Abstract

Background: Calf mortality represents a major production and livelihood constraint in the Somali region of Ethiopia. Disease was incriminated as a major underlying cause. However, epidemiology of major calf diseases in the region is not well documented.

Methods: Cross-sectional study was conducted between October 2014 and March 2015 to explore major camel calf (< 1 year) diseases and associated drivers in Gursosum and Kebribeya districts of Somali region. Participatory survey of camel husbandry and diseases was conducted on 51 camel holdings. Clinical and laboratory examination of health problems was performed on 189 camel calves.

Results: Camels accounted to 12.5% of average camel herds. Peak camel calving period was between October and March. Calving usually occurred from late-afternoon to night hours. Majority (90.2%) of producers restricted early colustrum intake and restricted milk sucking after 1 month. Further suckling restriction, introduction of green forages and herd mixing were practiced after 3 months of age. According to producers young calves were commonly affected by diarrhea (100%), orf (92.2%), respiratory illness (33.3%), plant poisoning (25.5%) and calf pox (7.9%). Major problems reported in older calves included; mange (94.1%) and tick (86.3%) infestations, ring worm (62.7%); camel pox (56.9%); trypanosomosis (51%) and respiratory illness (9.8%). Calf health investigation detected Sarcoptes scabius var cameli (16.4%) and mixed tick (H. dromedary, H. truncatum & R. pulchelis) (12.7%) infestations, diarrhea (3.7%) and respiratory illness (1.1%). Mange infection and plant poisoning were higher in Gursosum district whereas tick infestation was higher in small herds.

Conclusion: Camel calves were exposed to different debilitating and/or life threatening diseases. Potential risk factors include; inadequate colustrum feeding, under-nutrition, and premature exposure to endemic pathogens, vectors and harmful plants. Further epidemiological and intervention studies are recommended.

Introduction

The one humped camel (Camelus dromedarius) is multi-functional farm animal species uniquely adapted to arid and semi-arid zones. Ethiopia is home to an estimated 2.4 million camels found mainly in the arid to semi-arid regions [1]. For pastoralist and agro-pastoralist communities residing in these harsh environments, the camel represents a vital source of food, income and other services [2,3]. Developing camel production could offer a suitable alternative for meeting chronic and often escalating challenges of food insecurity in eastern Africa [4]. However, performance and hence livelihood and economic contribution of regional camel populations is very low owing to complex constraints such as; poor husbandry systems, widespread feed shortage and diseases, inadequate health and extension services, etc. [5].

Under east African pastoral/agro-pastoral production systems, heavy pre-weaning calf mortality represents a major impediment to camel herd growth and production potential. This is further compounded by low reproduction rates attributed to delayed maturation, long gestation period and long inter-calving intervals [6-8]. High camel calf mortality rate of up to 53.1%, before 1 year, has been reported in eastern Ethiopia [9]. Widespread diseases, malnutrition due to household competition for milk and predators accounted for the major share of these losses [5,6,10]. Studies in east Africa indicate that camel calves are susceptible to a wide range of diseases including; diarrhea, pox, contagious echyma, contagious skin necrosis, pneumonia, tick and mite infestations and internal parasites [11-13]. Withholding colostrum from neonates due to belief of many pastoralists that it causes fatal scouring was an important risk factor to heavy disease losses [4,14].

Epidemiological information on magnitude, causes and important risk factors of major calf diseases in the Somali region of Ethiopia is, at best, patchy. Therefore, the study attempted to describe major camel calf health problems and associated husbandry constraints in selected districts of the Ethiopian Somali region.

Methodology

Study area

The study was conducted in Gursosum and Kabribeya Districts of Fafem zone in the Ethiopian Somali Region. The altitude of Fafem zone

ranges between 1,500-1,800 m.a.s.l and the topography ranges from of flat to gentle slope, hilly and mountainous. The average annual rainfall from 300 mm to 500 mm and average monthly temperature ranges 16 to 20°C. Fafem zone is divided into three separate Food Economy Zones (FEZs), namely, sedentary agriculturalists (9.1%), agro pastoralists (56.8%) and pastoralists (34.1%) [15]. It has eight administrative districts, namely Jijiga, Kebribeyah, Harshin, Babile, Abware, Gursum, Tulul Guled and Gololchen. Of these, Gursum and Kebribeyah districts were selected for the study by considering accessibility of camel herds and representation of different production systems in the zone.

Study design

Participatory survey of camel producers and clinical examination of corresponding camel calf (<12 months) stocks was conducted Gursum and Kebribeyah districts from October 2014 to March, 2015. The study aimed to identify major health problems affecting camel calves and to describe corresponding animal, husbandry, and environment related risk factors in the study area.

Sampling

A total of 8 kebele’s were selected by random lottery method from a sampling frame of all Kebele’s in the two study districts. Subsequently, camel producers and corresponding calf stocks were sampled systematically by including every 5th consenting household during field visit to selected kebele’s. Taking logistic constraints in to account, a total of 51 camel rearing households and 189 calves aged ≤ 12 months were included in the study.

Data collection

Participatory interview survey was conducted on selected camel producers. Information pertaining to camel holding pattern, age related calf husbandry practices (early colustrum feeding, milk suckling, feeding forages, and housing/herding), and priority calf health problems was recorded using a semi-structured format prepared for the specific purpose. Local disease names were cross-checked against corresponding animal, husbandry, and environment related risk factors in the study area.

Calves (aged ≤ 12 months) in selected camel holdings were examined for clinical health status based on history and physical examination. Local disease names were cross-checked against reported symptoms to confirm disease identity.

Calving calf rearing practices

Participatory survey of camel producers and clinical examination of corresponding camel calf (<12 months) stocks was conducted Gursum and Kebribeyah districts from October 2014 to March, 2015. The study aimed to identify major health problems affecting camel calves and to describe corresponding animal, husbandry, and environment related risk factors in the study area.

Visible Ticks were manually collected from their attachment sites and placed in a universal bottle pre-filled with 70% alcohol. Skin scraping was collected from suspected cases of mange/mite infestation (exhibiting scales, crusts, alopecia and/or itching) in universal bottles pre-filled with 10% formalin according to [16]. All sample containers were properly labeled (household and animal id #, date, specimen type) and transported in an ice box to laboratories at College of Veterinary Medicine - Jigjiga University for analysis.

Tick species were identification based on standard procedure and morphological criteria as described by [17]. Skin scrapings were liquefied by adding KOH on petridish and examined under low power microscopy to identify species using a morphological key [18].

Statistical analysis

Participatory survey, clinical investigation and laboratory analysis data were entered on Microsoft Excel spreadsheets and analyzed using SPSS - 20 (SPSS inc). Numerical and categorical data were summarized using descriptive statistics (Mean ± SE and percentage (%)), frequency tables and graphs. Chi square test and comparison of means (independent-t and ANOVA tests) were used to draw inferential contrasts on camel holding patterns, calf rearing practices and health problems. Camel/calf holding sizes and calf age estimates were not normally distributed. Therefore, contrasts were made using natural logarithm (Ln) and reported in back transformed values. Statistical significance was determined at p<0.050.

Results

Camel holding pattern

Total herd size varied from 7 to 90 heads of camel with an average of 24.44 ± 1.08 camels/herd. Meanwhile, the size of calf stocks in herds varied from 1 to 11 and averaged 3.27 ± 1.07 calves/herd. Average total herd camel (p=0.016) and calf holdings (p=0.002) sizes were higher in Gursum (31.6 ± 3.14 camels and 4.23 ± 0.34 calves per herd) compared to Kebribeyah (22.45 ± 2.7 camels and 2.85 ± 0.32 calves per herd) district.

Calving calf rearing practices

Calving trends: According to surveyed camel producers, camels usually calved in late afternoon - evening hours 24 (47.1%) or during night time 20 (39.2%), and less commonly in the morning 7 (13.7%). Meanwhile, the calving month of calculated from reported calf age estimates showed higher (p<0.050) calving frequency during the long (Jilal) dry season (October -March) compared to the short (Haga) dry season as well as the Dira Gu (April-May) and Karan Gu (August-September) rainy periods (Figure 1a). Calving outside the long-dry season was comparatively more frequent (X²=7.8, p=0.039) in Gursum (34.8%) than Kebribeyah (17.5%) district (Figure 1b).

Colustrum provision: Only 5 (9.8%) of surveyed camel producers allowed full suckling of colustrum by the newborn calf on its first day of life. Remaining producers restricted initial colustrum intake by...
contagious eczema/orf 47 (92.2%), respiratory illness 17 (33.3%), plant poisoning 13 (25.5%) and camel pox 4 (7.9%). Meanwhile, mange
48 (94.1%) and tick 44 (86.3%) infestations; ring worm/dermatophytes
(alopoeia and scaliness) 32 (62.7%); camel pox (general illness plus
popular lesions around head) 29 (56.9%); trypanosomosis 26 (51%) and
respiratory illness 5 (9.8%) were frequently reported problems in
older growing (6-12 months) calves (Figure 2).

Plant poisoning in young (<6 months) calves was only reported
in Gursum (38.7%) district (p=0.001). Reporting frequency (RF) of
mange/mite infestation was higher (p=0.019) in Gursum (100%)
compared to Kebribeya (80%) district (Figure 3).

Field calf investigation: Examination of camel calves detected
64 (34.9%) apparent health problems including; Sarcoptes scabie var
cameli 31 (16.4%), tick infestation 24 (12.7%), diarrhea/scour 7 (3.7%)
and respiratory illness (nasal discharge and recent history of cough) 2
(1.1%). Tick infestations involves H. dromedary 22 (11.6%), R. pulchelis
19 (10.0%) and H. trancatum 16 (8.4%) species mainly as mixed
species affections (Table 1).

Mean age (months) of camel calves exhibiting diarrhea was
higher (p=0.000) than that of healthy calves or calves facing tick and
mange/mite infestation or respiratory illness (Figure 4). Prevalence of
mange/mite infestation was higher in Gursum 28 (21.2%) compared
to Kebribeya 3 (5.3%) district calf flocks (Table 2). Meanwhile, tick
infestation was more prevalent in small (<25 camel) 12/56 (21.4%)
compared to medium (25-50 camels) 8/106 (7.5%) or large (>50
camels) 4/27 (14.8%) herds (p=0.037).

Discussion

Overall camel holding pattern showed high variability among
limiting suckling 28 (54.9%) or partially milking colutrum before
the calf suckles 18 (35.3%). The practice was always associated to risk
of fatal scouring. Frequency of full suckling, restricted suckling and
milking - hand feeding in Gursum (9.7%, 51.6% and 38.7%,
respectively) and Kebribeya (10%, 10% and 80%, respectively) districts
showed variation (X²=9.7, p=0.003).

Feeding and watering: All participants reported that calves were
given only milk during the 1st months and milk plus water until 3
months of life thereafter. During the 1st month of life daily milk sucking
frequency ranged from ≥ 5 (94.1%) to ≤ 4 (5.9%) per day. Until the 3rd
month, 21.6% and 78.4% producers allowed ≤ 5 and ≤ 3 sucking per
day, respectively. After the 3rd month, sucking was reduced to 3 (7.8%)
and ≤ 2 (92.2%) times per day. Producers gradually initiated hand
feeding fresh-cut green grass/forages 12 (23.6%) or grazing on nearby
range plants 39 (76.5%) after latter age.

Housing/Herding: Majority of producers 42 (82.4%) kept the
newborn camel calf with its dam around homesteads during day
and in separate night enclosure until 3 months of age and 9 (17.6%) started
mixing neonates with older calves before latter age. After 3 months
of age, all mixed newborn calves with older immature herd mates for
daytime nearby range foraging and/or in night calf enclosures.

Calf health problems

Participatory survey: Overall, surveyed camel producers identified
nine major calf health problems showing (except for respiratory illness)
age-group related variations. Accordingly, the most frequently reported
young camel calf (<6 months) problems were; diarrhea 51 (100%),

according to study district (b).

Figure 2: Reporting frequency (RF) of major health problems relative to calf
age group.

Figure 3: Reporting frequency (RF) of major camel calf health problems
according to study districts.
Camel calves are born with an immature immune system. So they require immediate passive immune transfer through colostrum (first-milk) IgG intake within 24 hours of birth [22]. In contrast, majority (90.2%) of producers in the current study restricted early colustrum intake by limiting suckled volumes (54.9%) or by milking portions of the first-milk before calf is allowed to suckle (35.3%). The latter practice was frequent in Kebrhibeya district and could indicate more serious colustrum restriction as it denies any unobserved suckling opportunity in the first 24 hours of life. Camel pastoralists in Somali [10] and Borana [11] areas of Ethiopia and adjacent areas in eastern Africa [4,21,23] were widely recognized for restricting early colustrum intake. In contrast, [20] reported that up to 46.4% of camel producers in adjacent areas allow full colustrum suckling by camel newborns which could be attributed to difference of production systems covered by the study. In accordance with previous studies [4], the main reason for restricting early colustrum intake was a fear of fatal scour. In fact, camel colustrum is known to have powerful laxative effects attributed to its high total protein (15.8-19.5%) and mineral (1.4-2.8%) content [24]. However, risk of scour could be mitigated by dividing the optimum colustrum intake in to multiple feeding episodes mainly within 4 hours of birth as recommended for bovine calves [25].

Camel newborns were totally dependent on milk for nutrition during the first 3 months of life. However, milk suckling frequency was substantially restricted by majority of producers (78.4%) after the 1\textsuperscript{st} month of life. In addition, after age of 1 month camel producers were reported to limit the number of tests a calf is allowed to suckle using various forms of physical barriers [20]. Widespread practice of suckling frequency and teat access restrictions probably reflect magnitude of calf - human (household/market) competition for milk. Such early milk restrictions hold substantial negative implications to survival and growth of newborn camel calves. Others suggested that conflicting trends of rising consumer demand and stagnantly-low productivity was tipping competition for camel milk against calves and contributing to heavy mortality losses in eastern Africa [21,26].

The age of 3 months was a particularly critical transition phase for camel calves in the study area. At this age, all producers mixed calves with older herd-mates and gradually introduced green forages wherein milk intake in to multiple feeding episodes mainly within 4 hours of birth as recommended for bovine calves [25].

According to surveyed producers the diseases commonly affecting camel calves in the study area were; diarrhea, orf, mange and tick infestations, ring worm, camel pox, trypanosomosis, respiratory...
illness and plant poisoning in the given order. These were comparable to range of diseases reported from different areas in Ethiopia [6,7] and neighbouring countries [12,13,23,27]. Cross-sectional field investigation of camel calf (≤ 12 months) diseases detected mange (Sarcoptes scabiei var cameli) infestation (16.4%), mixed tick (H. dromedary, H. truncatum and R. pulchellus) infestation (12.7%), diarrhea (3.7%) and respiratory illness (1.1%). Ecto-parasite infestation and diarrhea were recognized to be the principal camel calf health problems in the study area [20]. A higher prevalence of mange (Sarcoptes scabiei) infestation has been reported for camels aged ≥ 1 year [28]. Meanwhile, a longitudinal study (covering all major seasons) of camel calf diseases in Borana reported higher prevalence of sarcoptic mange (47.9%) and tick (25.6%) infestations, diarrhea (5.1%) and respiratory infections (4.5%) [11]. Observed and/or reported frequency of plant poisoning and mange infestation were higher in Gursum compared to Kebribeya district which was probably attributed to agro-ecological variations. Heavy mange and tick infestation in camel calves reflects potentially substantial direct morbidity losses as well risk of tick borne diseases. Considering availability of reasonably effective and affordable control strategies, prevailing camel calf ecto-parasite infestation challenges reflect critical gaps in animal health services and/or producers awareness

Major camel calf diseases demonstrated distinct age dependent predisposition trends. Accordingly, diarrhea, orf and plant poisoning were more common in younger (<6 months) calves. In contrast, mange and tick infestation, ring worm, pox and trypanosomosis mainly affected older growing (6-12 months) calves. Newborn camel calves have little natural immunity [22]. In the face of inadequate early colusrum intake and poorly hygienic husbandry practices, camel neonates would be highly exposed to diverse environmental and contagious pathogens associated with diarrhea. Owing to absence of colustral passive immune transfer, contagious eatham/orf most commonly affects very young animals in endemic areas. Meanwhile, introduction of lush green forages to young calves lacking well developed foregut and intestines could also predispose digestive disorders like diarrhea. Likewise, premature range grazing could force small calves (having limited browsing reach) to consume potentially poisonous low-growing shrubs like Lantana camara which was abundant in Gursum district. On the other hand, mange and tick infestation, ring worm and trypanosomosis were contact/vector transmitted endemic problems having chronic and progressive nature. Therefore, these conditions are likely to surface some time after young camel calves start mixing with older potential infected herd-mates and grazing in vector infested rangelands. Meanwhile, camel pox has been characterized as strong maternal passive immune transfer and transmitting by tick (H. dromedary) vectors [29]. Therefore, risk of infection would naturally increase when contact with potentially infected animals and/or vectors increase after maternal antibodies in circulation had dwindled.

Camel calves in the study area face different health problems including contagious and environmental infections; ecto-parasite infestation, vector borne diseases; and plant poisoning. Inadequate early colusrum feeding, poor health and hygiene management, and premature herd mixing and release to rangelands could be important epidemiological determinants. Effect of health problems could be compounded by nutritional disorders associated to premature milk restriction and forage/grazing introduction. Successful rearing of camel calves requires improved husbandry and health care practices matched to the physiological need of animals and local distribution of disease agents. This demands deeper and more comprehensive epidemiological characterization of important camel calf health problems in different agro-ecological settings.
