**Reaction Conditions:** An oven dried 10 mL schlenk tube was charged with *meso*-1,2-dibromo-1,2-diphenylethane (0.3 mmol, 102 mg) and Methylene Blue (0.003 mmol, 1.1 mg). The contents were dissolved in 5 mL of dry DMF, followed by the addition of TMEDA (0.6 mmol, 90 µL). The reaction was purged with argon for 15 minutes, followed by irradiation with 2 warm white LEDs. The reaction mixture was extracted with ether (x3) and washed with brine (x5). The organic phase was dried with MgSO$_4$, and concentrated via rotary evaporation. Percent conversion and selectivity were determined by $^1$H NMR analysis.

\end{align*}
\]

**Reaction Conditions:** An oven dried 10 mL schlenk tube was charged with meso-1,2-dibromo-1,2-diphenylethane (0.3 mmol, 102 mg) and Ru(bpy)$_3$Cl$_2$ or fac-Ir(ppy)$_3$ (0.003 mmol). The contents were dissolved in 5 mL of dry DMF, followed by the addition of TMEDA (0.6 mmol, 90 µL). The reaction was purged with argon for 15 minutes, followed by irradiation with 2 warm white LEDs. The reaction mixture was extracted with ether (x3) and washed with brine (x5). The organic phase was dried with MgSO$_4$, and concentrated via rotary evaporation. E:Z ratios were determined by $^1$H NMR analysis.
G. Synthesis of 1-phenyl-1,2,3,4-tetrahydroisoquinoline

A 250 mL three-neck round bottom flask was charged with Cul (600 mg, 3.0 mmol) and K₃PO₄ (12.75 g, 60 mmol), and was evacuated and back-filled with argon. 2-Propanol (30 mL), ethylene glycol (3.33 mL, 30 mmol), 1,2,3,4-tetrahydroisoquinoline (6.0 mL, 45 mmol), and iodobenzene (3.36 mL, 30 mmol) were then added by syringe at room temperature. The reaction mixture was heated to 90 °C for 24 hours and then allowed to cool to room temperature. The reaction mixture was then diluted with diethyl ether (60 mL) and water (60 mL), and the organic layer was extracted with diethyl ether (x2). The organic phase was dried with MgSO₄, and the solvent was removed by rotary evaporation. The crude mixture was purified by flash column chromatography (20:1 Hexanes:EtOAc) to give the final product as an off-white solid (3.66 g, 58% isolated yield).

¹H NMR (400 MHz, CDCl₃): δ 7.34-7.27 (m, 2 H), 7.23-7.15 (m, 4 H), 7.00 (d, J=7.84 Hz, 2 H), 6.84 (t, J=7.25 Hz, 1 H), 4.43 (s, 2 H), 3.58 (t, J=5.88 Hz, 2 H), 3.00 (t, J=5.78 Hz, 2 H)

H. Light mediated Aza-Henry and control reactions using Methylene Blue

Note: For the following experiments, a 10 W 660 nm LED from LedEngin was used as the irradiation source to avoid any direct excitation of 1,3-diphenylisobenzofuran (DPBF).

Reaction Conditions: An oven dried 10 mL schlenk flask was charged with 2-phenyl-1,2,3,4-tetrahydroisoquinoline (0.3 mmol, 63 mg) and Methylene Blue (0.003 mmol, 1.1 mg). The contents were dissolved in 5 mL of a 4:1 mixture of MeCN:MeNO₂. The reaction was then irradiated for 2 h with a 10 W 660 nm LED. The reaction was then diluted with ether (20 mL) and H₂O (20 mL). The aqueous phase was extracted with ether (x2), and the combined organic phases were washed with brine, dried with MgSO₄, and concentrated by rotary evaporation. Yield reported as isolated yield.
**Reaction Conditions:** An oven dried 10 mL schlenk flask was charged with 2-phenyl-1,2,3,4-tetrahydrosisoquinoline (0.3 mmol, 63 mg) and Methylene Blue (0.003 mmol, 1.1 mg). The contents were dissolved in 5 mL of a 4:1 mixture of MeCN:MeNO₂, and was purged with argon for roughly 15 minutes. The reaction was then irradiated for 2 h with a 10 W 660 nm LED. The reaction was then diluted with ether (20 mL) and H₂O (20 mL). The aqueous phase was extracted with ether (x2), and the combined organic phases were washed with brine, dried with MgSO₄, and concentrated by rotary evaporation. Yield reported as isolated yield.

### I. Kinetic analysis of the Aza-Henry reaction with Methylene Blue

As shown in Section H, addition of 1,3-diphenylisobenzofuran (DPBF) to the reaction mixture results in a decrease in yield of the Aza-Henry product, and formation of 1,2-phenylenebis(phenylmethanone) is observed as a result of the oxidation of DPBF. However, this information alone is not enough to rule out that the decrease in yield of the Aza-Henry product could also stem from DPBF outcompeting 2-phenyl-1,2,3,4-tetrahydrosisoquinoline in the bimolecular quenching of Methylene Blue’s triplet. In order to rule out this possibility, the excited-state kinetics of Methylene Blue and all the reaction substrates were examined, and are summarized in Table S1.
Table S1. Bimolecular quenching data for $^3$Methylene Blue and the reaction substrates.

| Substrate                                      | $^3$MB $k_q$ (M$^{-1}$ s$^{-1}$) |
|------------------------------------------------|----------------------------------|
| O$_2$                                          | $2.49 \times 10^9$              |
| 2-phenyl-1,2,3,4-tetrahydrosisoquinoline       | $1.05 \times 10^9$              |
| DPBF                                           | $< 10^6$                        |
| MeNO$_2$                                       | $< 10^6$                        |

Since we could not detect any bimolecular quenching of $^3$Methylene Blue by DPBF, we can assume that the observed decrease in reactivity observed is due to DPBF trapping reactive oxygen species, and not from DPBF outcompeting 2-phenyl-1,2,3,4-tetrahydrosisoquinoline for Methylene Blue’s triplet.

Since it is well known that Methylene Blue is an excellent sensitizer of singlet oxygen ($^1$O$_2$), we decided to examine the bimolecular quenching of $^1$O$_2$ by the reaction substrates to determine the role of $^1$O$_2$ in the overall reaction mechanism. Moreover, it is well known that $^1$O$_2$ is capable of oxidizing amines$^1$, an important step in the proposed mechanism for the Aza-Henry reaction.$^{2,3}$ The results of this kinetic investigation are summarized in Table S2 (see Figures S19 and S20 for the corresponding bimolecular quenching plots).

Table S2. Bimolecular quenching data for $^1$O$_2$ and the reaction substrates.

| Substrate                                      | $^1$O$_2$ $k_q$ (M$^{-1}$ s$^{-1}$) |
|------------------------------------------------|----------------------------------|
| 2-phenyl-1,2,3,4-tetrahydrosisoquinoline       | $1.13 \times 10^8$              |
| DPBF                                           | $1.19 \times 10^9$              |
| MeNO$_2$                                       | $< 10^6$                        |

Figure S19. Representative kinetic bimolecular quenching plot for $^1$O$_2$ and 2-phenyl-1,2,3,4-tetrahydrosisoquinoline.
From these data, we can conclude that any $^1\text{O}_2$ produced by Methylene Blue can indeed be trapped by 2-phenyl-1,2,3,4-tetrahydroisoquinoline. In good agreement, we also obtain a value approaching diffusion control for DPBF, a known excellent $^1\text{O}_2$ quencher. Therefore, it is possible that $^1\text{O}_2$ is indeed playing a role in the mechanism, as the addition of another potent $^1\text{O}_2$ quencher (DPBF) significantly impacts the yield. However, DPBF is not solely specific to $^1\text{O}_2$, as it can also trap other reactive oxygen species, such as superoxide ($\text{O}_2^\cdot$). Therefore, we cannot conclude from these data alone that the trapping of $^1\text{O}_2$ is what is responsible for the decrease in the yield, but can only say that the decrease is due to the trapping of reactive oxygen species.

J. Excited Dye quenching by 2-phenyl-1,2,3,4-tetrahydroisoquinoline

K. Excited Dye quenching by molecular oxygen

General Procedure: Experiments at variable oxygen concentrations were carried out by using mixtures of oxygen and nitrogen prepared with a gas flow controller-mixer system. The concentration of oxygen was calculated using Henry’s law:

$$[O_2] = \frac{\rho}{K_H}$$

where $K_H$ is the Henry’s constant, and its value is 769.23 L•atm/mol for water and 131.25 L•atm/mol for acetonitrile; $\rho$ is the partial pressure of oxygen obtained from the mixer scale readings. Henry’s constant for acetonitrile was calculated under the assumption that acetonitrile under an atmosphere of air ($\rho_{O_2}$ = 0.21 atm) contains $1.6 \times 10^{-3}$ mol/L O$_2$. In cases where the solutions were comprised of a mixture of acetonitrile and water it was necessary to determine the number of moles of O$_2$ based on each of the components and then take into consideration the total volume of the mixed solution.

L. Spectral data of reaction products

According to the general procedure, meso-1,2-dibromo-1,2-diphenylethane (102 mg, 0.3 mmol), photosensitizer (0.003 mmol), and DMF (5 mL) were purged with argon and irradiated with two warm-white LEDs for 5 minutes. The reaction mixture was extracted with ether (x3) and washed with brine (x5) and concentrated to afford a crude product containing the title compound. Percent conversion was determined by $^1$H NMR (10-94% conversion).
\(^1\)H NMR: (400 MHz, CDCl\(_3\)): \(\delta\) 7.55-7.50 (m, 4 H), 7.40-7.34 (m, 4 H), 7.29-7.24 (m, 2 H), 7.12 (s, 2 H)

Reference: *J. Org. Chem.* 2015, 80, 6922.

According to the general procedure, 1-phenyl-1,2,3,4-tetrahydroisoquinoline (63 mg, 0.3 mmol), photosensitizer (0.003 mmol), and a mixture of MeCN:MeNO\(_2\) (4:1, 5 mL) were irradiated for 1 hour with two-warm white LEDs. The reaction was then diluted with ether (20 mL) and H\(_2\)O (20 mL). The aqueous phase was extracted with ether (x2), and the combined organic phases were washed with brine, dried and concentrated. The crude reaction mixture was purified by flash column chromatography (20:1 Hexanes:EtOAc) to afford the title compound as a yellow oil (9-66% isolated yield).

\(^1\)H NMR (400 MHz, CDCl\(_3\)): \(\delta\) 7.36-7.09 (m, 5 H), 6.99 (d, \(J=8.03\) Hz, 2 H), 6.89-6.82 (m, 1 H), 5.56 (t, \(J=7.25\) Hz, 1 H), 4.88 (dd, \(J=11.76,7.84\) Hz, 1 H), 4.57 (dd, \(J=11.76, 6.66\) Hz, 1 H), 3.73-3.55 (m, 2H), 3.18-3.01 (m, 1 H), 2.80 (dt, \(J=16.31, 4.97\) Hz, 1 H).

Reference: *J. Am. Chem. Soc.* 2010, 132, 1464.

According to the procedure described in Section H of the ESI, 2-phenyl-1,2,3,4-tetrahydrosisoquinoline (0.3 mmol, 63 mg), 1,3-diphenylisobenzofuran (0.05 mmol, 14 mg), Methylene Blue (0.003 mmol, 1.1 mg), and a mixture of MeCN:MeNO\(_2\) (4:1, 5 mL) was irradiated for 2 h with a 10 W 660 nm LED. The reaction was then diluted with ether (20 mL) and H\(_2\)O (20 mL). The aqueous phase was extracted with ether (x2), and the combined organic phases were washed with brine, dried and concentrated. The crude reaction mixture was purified by Prep TLC (20:1 Hexanes:EtOAc) to afford the final product as a white solid (6.5 mg, 46% isolated yield).

\(^1\)H NMR (400 MHz, CDCl\(_3\)): \(\delta\) 7.72-7.68 (m, 4 H), 7.62 (s, 4 H), 7.55-7.49 (m, 2 H), 7.41-7.34 (m, 4 H)

N. Determination of triplet energies by laser flash photolysis

In order to determine the triplet energy of the newly characterized dyes, quenchers with known triplet energies were employed, and their bimolecular quenching constants were determined using laser flash photolysis. Once no bimolecular quenching between the dye excited-state and the quencher was observed (<10^6 M^-1 s^-1), the triplet energy was calculated to be the midpoint between the failed quencher and the last quencher employed. The data for the determination of the triplet energies are summarized in Tables S3-S6 followed by their corresponding bimolecular quenching plots. The triplet energies for the following compounds can be found in the appropriate section of the Appendix section. All measurements were performed in acetonitrile, unless otherwise noted, using the same general procedure previously described.

Table S3. Bimolecular quenching values for New Methylene Blue N and a series of quenchers.

| Quencher                  | Quencher E_T (eV) | k_q (M^-1 s^-1) |
|---------------------------|-------------------|-----------------|
| O_2                       | 0.91              | 9.9 x 10^8      |
| 1,3-diphenylisobenzofuran | 1.47              | 2.9±0.5 x 10^8  |
| Perylene                  | 1.53              | 2.3±0.3 x 10^8  |
| Azulene                   | 1.69              | 1.2±0.1 x 10^8  |
| 9,10-diphenylantracene    | 1.77              | < 10^6          |

^1Performed in CH_2Cl_2
