Abstract

Background

Timely and appropriate health care seeking for diarrhea of under-five children is important to reduce severe and life-threatening complications. However, different findings indicate that mothers of under-five children often delay in seeking care which in turn contributes to the death of large number of children without ever reaching a health facility. Therefore, a proper understanding of determinants of delay in seeking care inform intervention strategies for health service planners. Objectives the aim of this study was to identify the determinants of delay in care seeking for diarrheal disease among Mothers/Caregivers of under-five children in Public Health Facilities of Arba Minch Town, South Ethiopia, 2019.

Methods

- Facility based Case Control study was conducted from March 4 to April 30, 2019. Total sample size was 400. Cases were selected by systematic random sampling technique while controls were mothers of under-five children with signs and symptoms diarrhea who came to the same health facility within 24 hours following cases. Data was collected by using pretested structured questionnaire by three data collectors and entered into EpiData V4 and exported to SPSS V23 for further analysis. Bivariable and Multivariable logistic regression was done and p-value <0.05 and 95%CI of AOR was used to declare statistical significance.

Result

- child sexAOR=1.93, (95%CI: 1.11,3.36), child ageAOR=4.47,95%CI:2.51,7.97), mothers’/caregivers educational status AOR=6.90, (95%CI:3.10,15.37), and AOR=3.12, (95%CI:1.44,6.73), household wealth index categoryAOR=2.81, (95%CI:1.20,6.58) and AOR= 2.61,(95%CI: 1.12, 6.09), response to first episode diarrhea AOR= 4.55, (95%CI:2.41,8.59), how the last six month visit helped for today’s visit AOR= 0.29,
(95%CI:0.15,0.55), and perceived health care professionals respectAOR=4.91, (95%CI:2.64,9.15) were important determinants of delay in seeking care.

Conclusions
-Sex and age of the child, educational status of the Mother/Caregiver, poor wealth index category, not visiting health facility at first response, satisfaction with the care and examination, and respect of health care professionals were important determinants of delay in seeking care among mothers/caregivers of under-five children with diarrhea illness. All concerned body should focus interventions on poor and less educated Mothers/Caregivers with emphasis on female children and <24 months. Health Workers are needed to provide respectful service to promote satisfaction level of clients.

Background
Globally, diarrheal disease is one of the five leading causes of morbidity and mortality among under-five children. In 2017 alone, 5.4 million children died before reaching their fifth birthday, out of all diarrheal deaths occurring among under-five children, Africa and South Asia jointly shared 78% in developing countries (1). Moreover, Sub-Saharan Africa remains the region with the highest under-five mortality rate in the world, with 76 deaths per 1,000 live births(2). In Ethiopia, 8% of under-five children mortality was contributed by the diarrhea(3). Seeking appropriate and prompt care could reduce by 20 percent of childhood deaths due to illnesses and prevent long-term complication(1). However, health care seeking behaviour was poor in Ethiopia and only a small proportion of under-five children receive appropriate treatment timely(4-7). EDHS 2016 shows that only 44% of under-five children with diarrheal diseases were taken for advice or treatment to a health facility. Different studies also identified low health care seeking behaviour of under-five children with diarrheal diseases(5, 8-11). In addition to that, even health care was sought, it was often delayed without ever reaching a health facility, and leads to morbidity and
mortality of large number of under-five children, otherwise leads to long term complications (5, 8-11). Ethiopian government has implemented Integrated Management of Childhood Illness (IMCI) protocols and community case management to improve both access to care and health care workers ability to address under-five illnesses, in addition to Health Extension Workers who provide community level disease prevention, health promotion and curative services. Moreover they were working to improve health care seeking behaviour of mothers/caregivers of under-five children with common childhood illness (12). As a result, the health care seeking behaviour has showed progress and it has increased from 13% in 2000, 22% in 2005, 32% in 2011 and 44% in 2016 (12, 13). In addition to that; the country has successfully achieved some of the Millennium Development Goals (MDGs), like reduction of under-five mortality by more than two-thirds, three years ahead the MDG deadline (1). A conceptual framework for determinants of delay in seeking timely care was adapted from Anderson health service utilization model. The model includes predisposing, enabling, need/disease and health system related factors and delay in seeking timely care was taken as outcome variable. Understanding the factors affecting the timely health care seeking behaviour is important for rational planning of intervention strategies, improve treatment compliance, evaluation of health care services and advance health promotion activities in a variety of contexts, particularly in Arba Minch Town, South Ethiopia. Identifying and having up-to-date evidence for the factors affecting the prompt health care seeking behaviour among mothers/caregivers of under-five children with diarrheal diseases in Ethiopia as well as at study area is essential and the result may assist town and zonal health program planners, local NGOs and other bodies interested in reducing mortality and morbidity of under-five children. Therefore, this study identified determining factors of delay in care seeking for diarrheal diseases among mothers/caregivers of under-five children who visit public health facility of Arba
Methods

**Study area, study design and study population**

The institution based case control study was conducted in Public Health Facilities of Arba Minch Town from March 4 to April 30, 2019. Arba Minch Town is one of the city administrations found in Gamo Zone of SNNPR, Ethiopia. Arba Minch Town is located at a distance of 495 km south from Addis Ababa, capital of Ethiopia, and 275 km south west away from Hawassa, the regional capital. The town administration has an estimated total population of 115,639 with Male = 58,051, Female = 57,588, a total of 18,051 under-five children in 2018/2019 G.C. It also has 1 general public hospital which is serving as referral hospital for the patients from surrounding districts in the zone as well as surrounding zones, and 2 public Health Centers (14). Arba Minch General Hospital has emergency pediatric, OPD pediatric and Inpatient pediatrics to provide health care service for children. Pediatric and child health OPD and wards has 4 pediatricians, 1 from Hospital and 3 from Arba Minch University and 4 GP, 6 Health Officer, 5 BSc Nurses, 7 Clinical Nurses, 1 IMNCI trained professional. Arba Minch Health Center and Shecha Health Center have 2 and 1 IMNCI trained professionals, respectively who provide the care for under-five children. All Mothers/Caregivers of under-five children with diarrheal illness who utilize health care services from Public Health Facilities of Arba Minch Town were source population, and those Mothers/Caregivers of under-five children with diarrheal disease who were visited Public Health Facilities during data collection period were study population. **Cases** were under-five children with signs/symptoms of diarrhea whose mothers sought treatment after 24-hours of the recognition of diarrhea(15, 16). **Controls** were under-five children with signs/symptoms of diarrhea whose mothers sought treatment within 24-hours of the recognition of diarrhea(15, 16). The inclusion criteria’s
considered for the study subjects was all mothers/caregivers of under-five children seeking care for any type of diarrhea and visiting Pediatric/IMNCI clinic of Public Health Facilities of Arba Minch Town.

**Sample size determination and sampling technique**

Sample size was determined using Epi Info Version 7 software by using sample size calculation formula for unmatched case control study. Sample size was calculated for maternal educational status, presence of severity signs and child’s age in months. Finally, we have taken child’s age in months as main exposure variable, with proportion of exposure among cases and controls was 74.1% and 60.1%, respectively, 80% of power, 95% confidence level, OR of 1.9, 1 to 1 case to control ratio, since it yields larger sample size, 380(15). Considering 5% nonresponse rate, the final total sample size was 400.

All the Public Health facilities found in Arba Minch Town were included in the study. Last year, 2010 EFY, same quarter 2-month report data was used to estimate number of participants from each health facility. Then, depending on that number, i.e. out of total 844 patients received care last year, sampling interval, K, was calculated, which was $2.11 \approx 2$. Proportional allocation of respondents to three public health facilities was done.

So, cases were selected by systematic random sampling technique where every other person was included and controls were patients who came to the same health facility following the cases. The first participant of the case group was selected by lottery method while the control was under-five child with diarrheal illness who come to the health facility following the cases but within the 24 hours of onset of diarrheal illness. When Mothers/Caregivers complained of diarrhea in their child completed their consultation with a health care professional, they were moved to a private room for an interview until the total required sample size obtained.

**Data collection procedure**
Data was collected using semi-structured interviewer administered questionnaire which was adapted from EDHS_2016(17) and it includes predisposing, enabling, need/disease factors, promptness of treatment seeking, client perception towards pharmacy service, client satisfaction by the health facility service and client perception towards respect of health care professionals. Two diploma nurses in Heath Centers and 1 BSc Nurse in the Arba Minch General Hospital who were not assigned in Under-five clinic to provide the service for children presenting with medical case were collected the data. Two BSc Nurses supervised data collectors on daily bases to maintain the quality of data. Cases and Controls were recruited from Hospital and Health Centers after they came to the facilities and are diagnosed with diarrhea and they were moved to private room to provide information.

**Data Quality Control**

The questionnaire was initially prepared in English and it was translated into Amharic, local language, and back into English by language experts, to check the consistency. Two-day training was given for data collectors and supervisors about the way of selecting study participants, way of interviewing and checking the already filled questionnaire by the principal investigator. Pretesting was performed at Shelle Health Center of Arba Minch Zuria district on 5% of sample size to check consistency and any ambiguity of the questionnaire a week back of actual data collection, then necessary revisions like some of the skipping pattern was modified. Data completeness was checked by the supervisor daily and weekly by the Principal Investigator for completeness and missing values.

**Data Processing and Analysis**

Data was entered into EpiData Version 4.4.2.1 and exported to SPSS version 23 for further analysis. Data cleaning and coding was conducted. Descriptive analysis was carried out and summarized by frequency tables, graphs and charts. Study participants’ household
wealth status was assessed by Principal component analysis. Then, participants were ranked into 3 groups, Poor, Middle, and Rich, based on the factor that explains largest variance in the included variables. The Hosmer Lemeshow statistics and deviance coefficient was used to check goodness of fit of the model and the model was good fit. No multicollinearity and outliers as it was checked by standard error of coefficients >2 and standardized residuals of >1.96 at 0.05 significance level respectively. Both bivariable and multivariable logistic regression was done to identify candidate variables and determinants of delay in seeking timely care, respectively. Statistical significance of variables at final model was declared at p-value <0.05 and 95% CI of adjusted odds ratio.

**Operational definitions**

**Caregiver:** - Any person above 18 years of age who is directly responsible for the care of the child at the time of the study(11, 18).

**Delay in seeking Care:** - Care that was sought from health facilities after 24 hours from the recognition of the presence of diarrhea in under-five children(15).

**Client perception towards pharmacy service:** - the perception of patients towards the pharmaceutical services provided in the health facility by pharmacy professionals were measured by 10 questions. The questions were organized to be responded in the Likert scale, ranging from 1(strongly disagree) to 5(strongly agree). Then, the mean score was calculated, and the scores above the mean were considered to have positive perception towards the pharmacy service and those who score below the mean were considered to have negative perception toward the pharmacy services(19).

**Client satisfaction:** - the satisfaction of patients with the service provided in the health facility by health professionals were measured with 12 questions. They were organized to be responded in the Likert scale, ranging from 1(Poor) to 5(Excellent). The, the mean value was calculated and those who score above the mean were considered to have good
satisfaction and those who score below the mean were considered to have poor satisfaction (19).

**Client perception towards respect of health workers:** the respect of health workers was measured in terms of patient’s response on the 5 questions provided. The questions were organized in Likert scale, ranging from 1 (strongly disagree) to 5 (strongly agree). Then, the mean score was calculated and those who score above the mean were considered as they got respect from health workers and those who score below the mean were considered that as they did not get respect from health workers (20).

**Results**

**Predisposing factors**

In this study 400 Mothers’/Caregivers’ (200 cases and 200 controls) were interviewed, making the response rate of 100%. The majority, 142 (71.0%) of the cases were children < 24 months but majority, 121 (60.5%) of controls were children ≥ 24 months. The age of cases ranges from 2 to 56 months, with a mean age of 22.24 (± 10.38SD) months and that of controls ranges from 2 to 58 months, with a mean age of 26.78 (± 12.22SD) months. More than half of respondents were females, 129 (64.5%) among cases but it was males 110 (55.0%) among controls (Table 1).

**Enabling factors**

Sixty-eight (34.0%) cases and 83 (41.5%) controls home was at a distance of 15-30 minutes from preferred health facility on foot. Seventy-four (37.0%) cases belong to poor wealth index, while 111 (55.5%) controls were among rich wealth index group. More than half, 107 (53.5%) cases and 103 (51.5%) controls responded that the cost of treatment at the health facility was easy. Examination given, 85 (42.5%) and short waiting time, 70 (35.0%) among cases and short waiting time, 89 (44.5%) among controls were the major reasons for the selection of Health Facility (Table 2).
**Need/disease related factors**

Most of the Mothers’/Caregivers’ 112 (56.0%) among cases, and 162 (81.0%) among controls responded to diarrhea of children by taking them to the health facility at the first episode. About 65 (32.5%) of cases and 47 (23.5%) of controls took their children immediately when diarrhea of children was complicated with blood. But, only 35 (17.5%) of cases and 53 (26.5%) of controls Mothers’/Caregivers’ reported that they seek medical care for any diarrhea. For the current diarrhea, 125 (62.5%) of cases and 75 (37.5%) of controls complained that child vomits everything eaten. Regarding type of diarrhea, 80 (40.0%) of Mothers/Caregivers of case group and 89 (44.5%) of Mothers’/Caregivers’ of control group complained watery type of diarrhea. The dehydration status of under-five children with diarrheal illness shows that 169 (84.5%) and 167 (83.5%) among cases and controls did not have dehydration respectively, some dehydration found to be 31 (15.5%) and 33 (16.5%) among cases and controls respectively, but no under-five child with severe dehydration among those who visited health facilities during study period (Table 3).

**Patient perception towards health system related factors**

Majority of respondents, 60.5% of case group have negative perception towards pharmacy service of the health facility, while about half of control group have such perception towards pharmacy service. Regarding client’s perception on respect of health care professional, more than half, 104 (52.0%) among cases and 160 (80.0%) among have good perception (Table 4).

**Determinants of delay in care seeking**

Bivariable and Multivariable Binary logistic regression result was presented with 95% CI of both COR and AOR to identify candidate variables for multivariable logistic regression and for determinants of delay in timely care seeking among mothers’/caregivers of under-five children with diarrheal illness, respectively. Multivariable Binary Logistic regression result
shows that sex and age of the child, Mother/Caregiver educational status, wealth index, mother/caregiver’s perception about the respect of health care professional, first response to child diarrhea, and how last visit helped were associated with delays in care seeking among mothers/caregivers of under-five children with diarrheal illness. The odds of being female was 1.93 times (AOR = 1.93, 95%CI:1.11, 3.36) higher in case group than controls as compared with male children. The odds of being young child (<24 months) was 4.47 times (AOR=4.47, 95%CI:2.51, 7.97) higher in case group than controls when compared with older age (≥24 months). The odds of not attending formal education and attending primary education was 6.9 times (AOR=6.90, 95%CI:3.10, 15.37) and 3.12 times (AOR = 3.12, 95%CI: 95%CI:1.44,6.73) higher in cases than controls as compared to college and above educational status. Household wealth index also has association with care seeking of mothers/caregivers of under-five children with diarrheal illness. The odds of poorest and poor wealth index category were 2.81 times (AOR=2.81, 95%CI:1.20,6.58) and 2.61 times(AOR=2.61,95%CI:1.12, 6.09) higher in cases than controls as compared to richest and rich wealth index category, respectively. The odds of did not visited health facility by mothers/caregivers of under-five children at first episode of diarrhea was 4.55 times (AOR=4.55,95%CI:2.41, 8.59) higher among cases than controls as compared to those who had visited health facility. The odds of satisfaction with the care and examination of the child in the previous visit was 0.29 times less (AOR=0.29,95%CI: 0.15-0.55) among cases than controls as compared to those who were only counseled on importance of early visit. Mothers/caregivers perception on the respect of health care professional was associated with the delay in seeking care. The odds of having poor perception on the respect of health care professional was 4.9 times (AOR=4.91,95%CI:2.64, 9.15) higher among cases than controls as compared to those with good perception(Table 5).

Discussion
This finding explored the predisposing, enabling, need/disease and health system related factors associated with delay in seeking health care for diarrheal illness and its overall result was in the expected direction and in line with most of the previous research findings in Jeldu, Woliso, Addis Ababa, Kersa district and Central Arsi Zone in Ethiopia, India, Rwanda and Global trends report(4-6, 11, 15, 21-24). Female children, children less than 24 months, Mothers/Caregivers without formal education and those attended only primary school, Mothers/Caregivers from poor wealth index households, Poor respondent’s perception on respect of health care professional, not visiting health facility as first response diarrhea, and Mothers/Caregivers who were satisfied with the care and examination of the child in the last six month were important predictors of delay in care seeking for diarrheal illness among Mothers/Caregivers of under-five children with diarrheal illness. The odds of being female was higher in case group than controls as compared with male children. The finding is consistent with previous research in Woliso in Ethiopia, India and rural Uganda(15, 21, 25) and study reported by Global DHS on care seeking and access to health care for childhood illness reported that males were more likely to seek care early(22). In addition, the existing literature in different developing countries regarding health care seeking for females display that female disadvantage in health care seeking(26). The possible reason for the difference in seeking care among Mothers/Caregivers of male and female children could be due to cultural influence, gender inequality, that systematically disadvantage females in the community, which, in turn may led to Mothers/Caregivers to pay attention only for males. However, this study is differed from studies conducted in Malaysia and Sierra Leone where sex had no significant association with either health care seeking and delay in seeking care(27-29).

The odds of being young child (<24 months) was higher in case group than controls when compared with older age (≥24 months). This finding is in line with previous study
from Woliso in Ethiopia, Niger and India (15, 21, 22, 30). This finding may be due to
Mother’s link diarrhea with eruption of teeth that in younger children result in mild and
self-limited diarrhea. However, this finding is in contrary to the study from Malaysia and
Global reports on trend in care seeking and access of health service utilization, where
young children were more likely to seek early care (22, 28). In addition to that, the age of
the child was not significant (7, 27).

The odds of not attending formal education and attending primary education was higher in
cases than controls as compared to college and above educational status. This pattern has
been shown consistently in previous studies from Woliso in Ethiopia, Slums of Addis Ababa
in Ethiopia, Global trends report of 2015, Malaysia and India DHS data analysis report (4,
15, 21, 22, 28). It is suggested that Mothers/Caregivers with no formal education or
attended only primary school were less likely to recognize severe symptoms in their sick
child, are more likely to seek traditional treatment and are less likely to have financial
and other resources to take the sick child to the health facility, so, they are more likely to
wait diarrhea improvement by itself at home. Moreover, Mothers/Caregivers with no formal
education may not have basic awareness about the effect of delay in seeking care for
children with diarrheal illness. However, this is in contrary to the EDHS 2011 and study
conducted in rural Niger (7, 30). This difference may be due to study design, study area
and sample size, since EDHS 2011 data analysis used large sample.

The odds of poor wealth index were higher in cases than controls as compared to rich
wealth index category. This study finding is consistent with the study from Slums of Addis
Ababa of Ethiopia, EDHS 2011, Global trend in care seeking, India DHS, Malaysia and
seven rural districts of Sierra Leone (4, 7, 21, 22, 27, 28). This may be due to a number of
factors, like lack of money to pay user fee/medicine cost, transportation cost to and from
health facility, and time lost from work/farming to take the child for treatment. However,
it was in contrary to the study from Woliso of Central Ethiopia, Jeldu district of Ethiopia and kigal in Rwanda, where monthly income/wealth index of respondents had no significant association with health care seeking behavior(11, 15, 24). This may be due to that respondents who have been utilizing these health facilities may have little variation in their capacity to pay service user fee or medicine cost in these study areas.

Visiting health facility at first episode of childhood diarrhea was associated with early care seeking of mothers. The odds of did not visited health facility by mothers/caregivers of under-five children as first response to diarrhea was higher among cases than controls as compared to those who had visited health facility. This study finding was consistent with the study conducted in Woliso of Central Ethiopia and Kersa district of Eastern Ethiopia(6, 15). This may be associated with the counseling from health care professional providing the service at the first episode of diarrhea on early visit to or the client may be satisfied with the service provided in the health facility. However, this finding is contrary to study conducted in Rwanda, where Mothers/Caregiver of under-five children with diarrheal illness who had first consultation at public health institution were more likely to be delayed(24). This may be due to Mothers’/Caregivers of under-five children may be dissatisfied with the service provided and may wait at home or take the sick child to traditional treatment, so they may take their sick child after complications has developed.

The odds of satisfaction with the care and examination of the child in the previous visit was lower among cases than controls as compared to those who were only counseled on importance of early visit. This study finding is consistent with the study conducted in Woliso of Central Ethiopia and evidence based national survey of Ethiopia(15, 31).

Health care professionals respect to clients was also important determinant of delay in seeking health care in this study. The odds of having poor perception on the respect of health care professional was higher among cases than controls as compared to those with
good perception. However, the effect of this variable was not studied previously.

Cost of treatment, health facility distance were not predictors of delay among mothers/caregivers of under-five children with diarrheal illness. This is contrary to other studies that cited cost and distance from nearby health facility as an important determinant for delay in seeking and not seeking health care. However, different studies in Ethiopia and Niger support this finding. The difference may be due to the fact that capacity to pay for service fee or medicine cost at health facilities may not vary to a large extent, so that most of them report that the cost is easy to pay. In addition, this study was conducted in town administration where most of the study participants were from the town, distance is less likely to be barrier for early seeking health care.

Conclusions

This study revealed that child’s age in months, child sex, educational status of the Mother/Caregiver, visiting health facility as first response to childhood diarrhea, wealth index category of the household, health care professionals respect to the clients during service provision were important determinants of delay in seeking health care among mothers/caregivers of under-five children. On the other hand, Mothers/Caregivers who were satisfied with care and examination of the child in the previous last six month visit to the health facility has protective effect on the delay in seeking health care among Mothers/Caregivers of under-five children with diarrheal illness. Consider intervention on misinterpretation of diarrheal disease among children <24 months and cultural practices with emphasis on poor and less educated families, families with female under-five children to have largest impact on child health improvement programme. awareness creation on effect of delayed care seeking and diarrhea danger signs among Mothers/Caregivers of under-five children should also be well thought-out.

Declarations

Authors contributions: AF conceived and designed the study, developed the data collection instruments, performed the statistical analysis and wrote first version of the manuscript. GA and DH design, implementation, analysis and writing. All authors critically revised and approved the final manuscript.

Availability of data and materials: For those who are interested; the datasets of this study could be accessed from the corresponding author on reasonable request.

Consent to publish

Not applicable. But we didn’t take image, voice and video at all. By considering the benefit of the study the findings is submitted for publication.

Competing interests: The authors declare that they have no competing interests.

Funding: Not applicable

Participant consent: Obtained

Acknowledgement We are grateful to almighty lord. We also extend our appreciation to Arba Minch University, College of Medicine and Health Science, Department of Public Health, study participants, data collectors, Supervisors, Arba Minch Town Health Unit, Arba Minch General Hospital Managers, Arba Minch and Shecha Health Centers.

Ethics and consent to participate

Ethical approval was obtained from the Institutional Review Board of Arba Minch
University, College of Medicine and Health Science. A formal letter was written to Arba Minch Town health office and Arba Minch General Hospital for permission and support by Arba Minch University Department of Public Health. Then permission letter was written from Arba Minch Town health Unit to Health Centers. Informed verbal consent was obtained from actual study. Health education on the effect of delayed care seeking was given on spot for those who came to health facility after 24 hours of recognizing symptoms of diarrhea. The aim of study was clearly explained to the mothers/caregivers of children of under-five years. The data was de-identified, de-linked and stored in a secure location. Respondents were assured about the confidentiality of the information they provided as well as their right to withdraw at any time during interview.

## Tables

Table 1: Predisposing factors of delay in seeking care among mothers/caregivers of <5 children with diarrheal diseases in Public Health Facilities of Arba Minch Town, South Ethiopia, 2019 (n = 400).

| Variables                                      | Cases = 200 | Controls = 200 |
|------------------------------------------------|-------------|----------------|
| Age of child in months                         |             |                |
| <24                                            | 142         | 71             |
| ≥24                                            | 58          | 29             |
| Sex of the child                               |             |                |
| Male                                           | 71          | 35.5           |
| Female                                         | 129         | 64.5           |
| Birth order of the child                       |             |                |
| ≤2                                             | 120         | 60.0           |
| 3-4                                            | 76          | 38.0           |
| ≥5                                             | 4           | 2.0            |
| Age category of the mother/caregiver           |             |                |
| 15-25                                          | 94          | 47.0           |
| 26-34                                          | 81          | 40.5           |
| ≥35                                            | 25          | 12.5           |
| Number of under-five children in the house hold|             |                |
| 1-2                                            | 83          | 41.5           |
| 3-4                                            | 74          | 37.0           |
| ≥5                                             | 43          | 21.5           |
| Place of residence                             |             |                |
| Rural                                          | 54          | 27.0           |
| Urban                                          | 146         | 73.0           |
| Educational level of mother/caregiver          |             |                |
| No formal education                            | 79          | 39.5           |
| Primary Education                              | 50          | 25.0           |
| Secondary Education                            | 44          | 22.0           |
| College and above                              | 27          | 13.5           |
| Educational Level of father                    |             |                |
| No formal education                            | 19          | 9.5            |
| Primary education                              | 58          | 29.0           |
| Secondary education                            | 84          | 42.0           |
| College and above                              | 39          | 19.5           |
| Knowledge of diarrhea danger sign              |             |                |
