A COUNTEREXAMPLE TO DISPERSIVE ESTIMATES FOR
SCHRÖDINGER OPERATORS IN HIGHER DIMENSIONS

M. GOLDBERG AND M. VISAN

ABSTRACT. In dimension $n > 3$ we show the existence of a compactly supported potential in the differentiability class $C^\alpha$, $\alpha < \frac{n-3}{2}$, for which the solutions to the linear Schrödinger equation in $\mathbb{R}^n$,

$$-i\partial_t u = -\Delta u + Vu, \quad u(0) = f,$$

do not obey the usual $L^1 \to L^\infty$ dispersive estimate. This contrasts with known results in dimensions $n \leq 3$, where a pointwise decay condition on $V$ is generally sufficient to imply dispersive bounds.

1. Introduction

The evolution operator for the free Schrödinger equation, here denoted by $e^{-it\Delta}$, is subject to a wide variety of estimates. Functional analysis dictates that it must be an isometry on $L^2(\mathbb{R}^n)$ at every fixed time $t$. Representing $e^{-it\Delta}$ as a convolution operator with the kernel $(-4\pi it)^{-\frac{n}{2}} e^{-|x|^2/(4t)}$, leads to the dispersive bound

$$\| e^{-it\Delta} f \|_\infty \leq (4\pi |t|)^{-\frac{n}{2}} \| f \|_1$$

valid for each $t \neq 0$. Between these two estimates one already has most of the necessary elements to verify more subtle space-time properties of the Schrödinger evolution such as global Strichartz bounds.

It is natural to ask whether a perturbed operator $e^{itH}, H = -\Delta + V$, can satisfy (up to a constant) the same $L^1 \to L^\infty$ estimate as the free evolution. In general, it cannot. If $H$ has point spectrum (eigenvalues), the naive dispersive estimate (1.1) fails. Indeed, for any Schwartz function $f$ that has nonzero inner product with an eigenfunction, $\langle e^{itH} f, f \rangle$ does not converge to zero as $t \to \infty$. Therefore, it is a natural endeavour to prove

$$\| e^{itH} P_{ac}(H) f \|_\infty \leq C |t|^{-\frac{n}{2}} \| f \|_1,$$

where $P_{ac}(H)$ denotes the projection onto the absolutely continuous spectrum\footnote{For the potentials discussed here, there is no singular continuous spectrum by the Agmon-Kato-Kuroda Theorem.} of $H$.

It is known that (1.2) can fail for $t$ large in the presence of a zero-energy eigenvalue or resonance. For more details, see [7, Theorem 10.5], [5, Theorem 8.2], and [8, §3]. By assuming that zero is a regular point, that is, neither an eigenvalue nor a resonance of $H$, one can find conditions governing the decay and regularity (but not the size, or signature) of $V$ which are known to be sufficient to imply the dispersive bound (1.2). These are listed below for reference.

- $[3] \quad n = 1: \quad (1 + |x|)V \in L^1(\mathbb{R})$
- $[13] \quad n = 2: \quad |V(x)| \leq C(1 + |x|)^{-3-\varepsilon}$
\[ V \in L^{2-\varepsilon}(\mathbb{R}^3) \cap L^{2+\varepsilon}(\mathbb{R}^3) \]

\[ \hat{V} \in L^1 \text{ and } (1 + |x|^2)^{\gamma/2}V(x) \text{ is a bounded operator on the} \]
Sobolev space \( H^\nu \) for some \( \gamma > n + 4 \) and some \( \nu > 0 \)

For a more thorough discussion of the work on this problem, see the survey [14].

One might extrapolate from the results in dimensions 1, 2, and 3 that a suitable \( L^p \)-type condition for potentials should be sufficient in every dimension. The main result of this paper, Theorem 5.5, shows that this is not true: In every dimension \( n > 3 \), there exist continuous and compactly supported potentials for which the dispersive estimate (1.2) fails.

In constructing the counterexamples, we follow the approach of [3] and [2]. Specifically, we use Stone’s formula to construct the spectral measure from the resolvent, which in turn is studied via a finite Born series expansion (iteration of the resolvent identity). While we do not explicitly separate the contributions of high and low energies, the failure of dispersive estimates in this case should be recognized as a high-energy phenomenon.

The three dimensional analysis of [3] relies heavily on the simple explicit expression of the free resolvent. The free resolvent can be written in terms of elementary functions in all odd dimensions; however, the expressions become increasingly unwieldy as the dimension increases. In even dimensions, Bessel/Hankel functions are required. The key to avoiding this morass is the introduction of certain symbol classes, \( S^{i,j} \), which capture the essential features of the free resolvent. In particular, in dimension \( n \), one must integrate by parts approximately \( (n + 1)/2 \) times to obtain the appropriate power of \( t \); this seems quite impossible without such a unifying tool.

In dimensions four and higher, the Green's function is rather singular at the origin, specifically, it is not locally square integrable. This necessitates carrying the Born expansion much further than in [3], which adds to the complexity of our proof.

Our analysis contains certain partial positive results. To be precise, we show that (1.2) is attained by the tail of the Born series, taken after a finite number (depending on the dimension) of initial terms. The question of whether \( e^{itH}P_{ac}(H) \) is dispersive then reduces to an estimate on the initial terms in the Born series. We construct a potential for which the sum of these terms is bounded below by \( |t|^{-\alpha}, \alpha > \frac{n}{2} \), at certain times \( 0 < t < 1 \). In the limit \( t \to 0 \), this runs contrary to the desired bound of \( |t|^{-\frac{n}{2}} \). The Uniform Boundedness Principle is used to show that the worst possible limiting behaviour can be achieved.

It should again be emphasized that the non-dispersive phenomenon takes place over extremely short times; moreover, it is a high-energy phenomenon. Indeed by Theorem B.2.3 of [15], for any bounded compactly supported function \( \phi \), the operator \( e^{itH}\phi(H) \) maps \( L^1 \) into \( L^\infty \) uniformly in \( t \). This is true for very general potentials, in particular those that are bounded.

A physical interpretation is that even high-frequency waves travelling with large velocity can be effectively scattered by a non-smooth potential. Depending on the geometry of the potential, the first reflection may generate an unacceptable degree of constructive interference. For the purposes of our counterexample, “non-smooth” will mean that \( V \) is assumed to possess fewer than \( \frac{n-3}{2} \) continuous derivatives.

Compare this to the smoothness conditions in [8], which are sufficient to imply a dispersive bound. In that paper a potential is only explicitly required to possess
derivatives of order \( \nu \) for some \( \nu > 0 \). Indeed, there exist numerous examples of functions satisfying all the hypotheses of [8], yet which we would consider to be non-smooth. On the other hand, the potentials constructed in this paper are differentiable to order \( \frac{3n-3}{2} \) but the dispersive estimate still fails. This suggests that while a dispersive bound may hold for all sufficiently smooth potentials (with rapid decay at infinity), other criteria besides the number and size of derivatives determine what happens in the absence of such strong regularity.

The additional assumption in [8] is that \( \hat{V} \in L^1 \), which is satisfied by any potential in the Sobolev space \( H^{\frac{3n}{2}}(\mathbb{R}^n) \). Determining which functions of lesser regularity also have integrable Fourier transform is a well known difficult problem.

The counterexample constructed here is motivated by a different and explicitly geometric consideration, the focal pattern of reflections caused by an elliptical surface. Strictly speaking, the reflection is caused by a highly oscillatory potential whose level sets are ellipses. When presented in this light, it is clear that some notion of curvature and/or convexity can also determine whether dispersive estimates remain valid. There is still considerable room between the currently known sufficient conditions and the negative result presented here. We believe this middle ground can be explored via some combination of geometric and Fourier analysis and that these are most likely two sides of the same coin.

2. Notes on the free resolvent

We introduce here a class of symbols which will be relevant in the study of the free resolvent, simplifying both the notation and the analysis. For \( i, j \in \mathbb{Q} \), we denote by \( a_{i,j} \) a symbol belonging to the class \( S^{i,j} \), i.e., a symbol that satisfies the following estimates:

\[
\left| \frac{\partial^k a_{i,j}(x)}{\partial x^k} \right| \leq \begin{cases} 
  c_k x^{i-k} & \text{if } 0 < x \leq 1, \\
  c_k x^{j-k} & \text{if } x > 1 
\end{cases} \quad \forall k \geq 0.
\]

The calculus of these symbols is quite straightforward: the derivative of a symbol in \( S^{i,j} \) is a symbol in \( S^{i-1,j-1} \) and the product of a symbol in \( S^{i,j} \) with a symbol in \( S^{i',j'} \) is a symbol in \( S^{i+i',j+j'} \). In particular, the product of a symbol in \( S^{i,j} \) with \( x^\alpha \) belongs to \( S^{i+i\alpha,j+j\alpha} \).

Now let us consider the resolvent of the free Schrödinger equation,

\[ R_0(z) = (-\Delta - z)^{-1}. \]

In dimension \( n \geq 4 \), \( R_0(z) \) is given by the kernel:

\[ R_0(z)(x,y) = \frac{i}{4} \left( \frac{z^\frac{3}{2}}{2\pi |x-y|} \right)^{\frac{3}{2}-1} H^{(1)}_{\frac{3}{2}-1}(z^\frac{1}{2}|x-y|), \]

where \( \text{Im} \, z^\frac{3}{2} \geq 0 \) and \( H^{(1)}_{\frac{3}{2}-1} \) is the first Hankel function.

We encode the information contained in the asymptotic expansions of the first Hankel function near the origin and at infinity (see [1]), together with the information provided by the differential equation satisfied by the first Hankel function,

\[ H^{(1)}_{\nu-1}(z) - H^{(1)}_{\nu+1}(z) = 2 \frac{d}{dz} H^{(1)}_{\nu}(z), \]

into the following formula valid for \( \text{Re} \nu > -\frac{1}{2} \) and \( |\arg z| < \pi \),

\[ H^{(1)}_{\nu}(z) = e^{iz} a_{-\nu, -\frac{1}{2}}(z). \]
This together with (2.1) yield a representation for the kernel of the free resolvent in dimension $n \geq 4$ in terms of the aforementioned symbols, that is,

$$R_0^\pm (\lambda^2)(x,y) = a_{n-2, \frac{n-2}{2}}(\lambda|x-y|) \frac{e^{\pm i\lambda|x-y|}}{|x-y|^{n-2}},$$

where $R_0^\pm (\lambda^2)$ denote the boundary values $R_0(\lambda^2 \pm i0)$.

Let us also point out a similar formula for the imaginary part of the free resolvent,

$$\text{Im} \ R_0(\lambda^2)(x,y) = a_{n-2, \frac{n-2}{2}}(\lambda|x-y|) \frac{e^{\pm i\lambda|x-y|}}{|x-y|^{n-2}},$$

by which we mean that we can write it as the sum of two terms of this type, one with phase $e^{i\lambda|x-y|}$ and the other with phase $e^{-i\lambda|x-y|}$. Indeed, using (for example) the identity

$$\lambda^{n-2}(-\Delta - 1)^{-1}(\lambda x) = (-\Delta - \lambda^2)^{-1}(x)$$

for the kernels of the free resolvents, we can write

$$\text{Im} \ R_0(\lambda^2)(x,y) = \lambda^{n-2}(\lambda|x-y|) J_{n-2}(\lambda|x-y|),$$

where $J_{n-2}$ denotes the Bessel function near the origin and at infinity (see again [4]) and using the differential equation satisfied by the Bessel function,

$$J_{\nu-1}(z) - J_{\nu+1}(z) = 2 \frac{d}{dz} J_{\nu}(z),$$

one easily derives (2.3).

The purpose of understanding the free resolvent is that it enables us to study functions of $H$ through to the Stone formula for the spectral measure:

$$\langle F(H)P_{ac} f, g \rangle = 2 \int_0^{\infty} F(\lambda^2) \lambda \langle E'(\lambda^2) f, g \rangle d\lambda$$

$$= \frac{2}{\pi} \int_0^{\infty} F(\lambda^2) \lambda \langle \text{Im} \ R_V(\lambda^2) f, g \rangle d\lambda,$$

where $f, g$ are any two Schwartz functions, $P_{ac}$ denotes the projection onto the absolutely continuous spectrum of $H$, $E'(\lambda)$ denotes the spectral measure associated to $H$, and $R_V^\pm (\lambda^2) := (H - \lambda^2 \pm i0)^{-1}$ is the resolvent of the perturbed Schrödinger equation. We have chosen signs so that $2i \text{ Im} \ R_V(\lambda^2) = R_V^+(\lambda^2) - R_V^-(\lambda^2)$.

In order to compute the kernel of $\text{Im} \ R_V(\lambda^2)$, we make use of the resolvent identity:

$$R_V^+(\lambda^2) = R_0^+(\lambda^2) - R_0^+(\lambda^2)V R_V^+(\lambda^2),$$

which by iteration gives rise to the following finite Born series expansion:

$$R_V^+(\lambda^2) = R_0^+(\lambda^2) + \sum_{l=0}^{2m+1} R_0^+(\lambda^2)[-V R_0^+(\lambda^2)]^l$$

$$+ R_0^+(\lambda^2)V[R_0^+(\lambda^2)V]^m R_0^+(\lambda^2)[VR_0^+(\lambda^2)]^m VR_0^+(\lambda^2).$$

Elementary algebra can also be used to solve for $R_V^+(\lambda^2)$ in terms of $R_0^+(\lambda^2)$:

$$R_V^+(\lambda^2) = (I + R_0^+(\lambda^2)V)^{-1} R_0^+(\lambda^2) := S^+(\lambda^2) R_0^+(\lambda^2)$$
For now this identity is only a formal statement, as we have not shown that $S^\pm(\lambda^2) = (I + R_0^\pm(\lambda^2)V)^{-1}$ exists as a bounded operator on any space. Existence and uniform boundedness of $S^\pm(\lambda^2)$ will be demonstrated in Section 4.

3. USEFUL LEMMAS

In this section we prove a few technical lemmas. We begin with certain results related to the boundedness of the Riesz potentials between various weighted spaces.

By Riesz potentials, we mean the operators

$$I_\alpha : f \mapsto |x|^{\alpha-n} * f$$

where $0 < \alpha < n$.

Let $\mathcal{I}_q$ denote the space of compact operators $T$ for which $\|T\|_{\mathcal{I}_q} = [\text{tr}(|T|^q)]^{\frac{1}{q}}$ is finite. We recall the following well-known result (see [10, Theorem XI.20]):

**Lemma 3.1.** Let $f, g \in L^q(\mathbb{R}^n)$, for some $2 \leq q < \infty$. Then, $f(x)g(-i\nabla) \in \mathcal{I}_q$ and

$$\|f(x)g(-i\nabla)\|_{\mathcal{I}_q} \leq (2\pi)^{-\frac{n}{2}} \|f\|_q \|g\|_q.$$

Here, $f(x)$ denotes multiplication by $f$ in physical space, while $g(-i\nabla)$ denotes multiplication by $g$ in frequency space.

As a consequence of Lemma 3.1, one can derive results on the boundedness of the Riesz potentials between various weighted spaces. To describe these spaces, we will use the notation

$$\|f\|_{L^p,\sigma} := \|\langle x \rangle^\sigma f\|_{L^p},$$

where $\langle x \rangle := (1 + |x|^2)^{1/2}$, $1 \leq p \leq \infty$, and $\sigma \in \mathbb{R}$. Following the notation of Jensen and Kato, we write $B(0, \sigma; 0, -\sigma')$ for the set of bounded operators from $L^{2,\sigma}$ to $L^{2,-\sigma'}$, while $B_0(0, \sigma; 0, -\sigma')$ denotes the set of compact operators from $L^{2,\sigma}$ to $L^{2,-\sigma'}$. Jensen shows (see Lemma 2.3 in [15]) the following result.

**Proposition 3.2.** 1) If $0 < \alpha < \frac{n}{2}$, $\sigma, \sigma' \geq 0$, and $\sigma + \sigma' \geq \alpha$, then $I_\alpha \in B(0, \sigma; 0, -\sigma')$. Moreover, if $\sigma + \sigma' > \alpha$, then $I_\alpha \in B_0(0, \sigma; 0, -\sigma')$.

2) If $\frac{n}{2} \leq \alpha < n$, $\sigma, \sigma' > \alpha - \frac{n}{2}$, and $\sigma + \sigma' \geq \alpha$, then $I_\alpha \in B(0, \sigma; 0, -\sigma')$. Moreover, if $\sigma + \sigma' > \alpha$, then $I_\alpha \in B_0(0, \sigma; 0, -\sigma')$.

The case $\alpha \geq n$ may appear qualitatively different from the Riesz potentials considered above; however, the mapping bounds between weighted $L^2$ spaces are still valid.

**Proposition 3.3.** Let $\alpha \geq n$. The convolution operator $I_\alpha := f \mapsto |x|^{\alpha-n} * f$ is an element of $B_0(0, \sigma; 0, -\sigma')$, provided $\sigma, \sigma' > \alpha - \frac{n}{2}$.

**Proof.** As every Hilbert-Schmidt operator is compact, in order to prove the proposition it suffices to show that $I_\alpha$ is a Hilbert-Schmidt operator between $L^{2,\sigma}$ and $L^{2,-\sigma'}$. In turn, this is equivalent to showing the finiteness of the integral

$$\iint \langle x \rangle^{-2\sigma} |x - y|^{2(\alpha-n)} \langle y \rangle^{-2\sigma'} \, dx \, dy.$$

Consider the integral with respect to $x$, namely

$$\int \langle x \rangle^{-2\sigma} |x - y|^{2(\alpha-n)} \, dx.$$
If \(|y| \leq 1\), this is dominated by the integral of \(\langle x \rangle^{2(\alpha - \sigma - n)}\), which is finite because \(\sigma > \alpha - \frac{n}{2}\).

Now suppose \(|y| > 1\). Over the region where \(|x| \leq \frac{1}{2}|y|\), the factor \(|x - y|\) is essentially of size \(|y|\), as can be seen from the triangle inequality. Meanwhile, the factor \(\langle x \rangle^{-2\sigma}\) is integrable because \(\sigma > \alpha - \frac{n}{2} \geq \frac{n}{2}\). Consequently, the integral over this region is bounded by \(|y|^{2(\alpha - n)}\), i.e.,

\[
\int_{|x| \leq \frac{1}{2}|y|} \langle x \rangle^{-2\sigma} |x - y|^{2(\alpha - n)} dx \lesssim |y|^{2(\alpha - n)}.
\]

Over the region where \(|x - y| \leq \frac{1}{2}|y|\), the triangle inequality dictates \(|x| \sim |y|\).

Hence,

\[
\int_{|x - y| \leq \frac{1}{2}|y|} \langle x \rangle^{-2\sigma} |x - y|^{2(\alpha - n)} dx \lesssim \langle y \rangle^{-2\sigma} \int_{|x - y| \leq \frac{1}{2}|y|} |x - y|^{2(\alpha - n)} dx \lesssim \langle y \rangle^{-2\sigma} |y|^{2\alpha - 2\sigma - n}.
\]

Everywhere else in \(\mathbb{R}^n\), the two functions \(|x|\) and \(|x - y|\) are of comparable size. Recalling that \(\sigma > \alpha - \frac{n}{2}\), the integral over this region is then dominated by

\[
\int_{|x| > \frac{1}{2}|y|} \langle x \rangle^{-2\sigma} |x|^{2(\alpha - n)} \lesssim \int_{|x| > \frac{1}{2}|y|} |x|^{2(\alpha - \sigma - n)} \lesssim |y|^{2\alpha - 2\sigma - n}.
\]

Therefore, the dominant term for large \(y\) comes from the region \(|x| \leq \frac{1}{2}|y|\). To complete the estimate for the Hilbert-Schmidt norm, it remains to bound the integral over the \(y\)-variable. As \(\sigma' > \alpha - \frac{n}{2}\), this is dominated by

\[
\int \langle y \rangle^{2(\alpha - n)} \langle y \rangle^{-2\sigma'} dy \lesssim 1.
\]

This concludes the proof of Proposition 3.3. \(\square\)

Propositions 3.2 and 3.3 immediately yield some mapping bounds for the free resolvent and its derivatives. Indeed, we have

**Corollary 3.4.** Let \(j\) be any nonnegative integer and suppose \(\sigma, \sigma' > j + \frac{1}{2}\) with \(\sigma + \sigma' > j + \frac{n+1}{2}\). Then

\[
\left\| \left( \frac{d}{d\lambda} \right)^j R_0^\pm (\lambda^2) f \right\|_{L^2, -\sigma'} \lesssim \lambda^{-j} \langle \lambda \rangle^{j + \frac{n+1}{2}} \| f \|_{L^2, -\sigma}.
\]

**Proof.** Recall that the kernel of \(R_0^\pm (\lambda^2)\) is given by \(|x|^{2-n} e^{\pm i\lambda |x|} a_{0, \frac{n+2}{2}+j}(\lambda |x|)\). When a symbol is differentiated, the effect is comparable to dividing by \(\lambda\); see Section 2 for the calculus of the symbols \(a_{i,j}\). Each derivative that falls on the exponential factor increases the power of \(|x|\) by one.

Based on these possible outcomes, the integral kernel of \((\frac{d}{d\lambda})^j R_0^\pm (\lambda^2)\) must be of the form \(\lambda^{-j} |x|^{2-n} e^{\pm i\lambda |x|} a_{0, \frac{n+2}{2}+j}(\lambda |x|)\), which is dominated pointwise by the kernel of \(\lambda^{-j} I_2 + \lambda^{\frac{n-1}{2}+j} I_{\frac{n+1}{2}+j}\). Thus, for the kernels, we have the pointwise inequality

\[
(3.1) \quad \left( \frac{d}{d\lambda} \right)^j R_0^\pm (\lambda^2) \lesssim \lambda^{-j} \langle \lambda \rangle^{j + \frac{n+1}{2}} (I_2 + I_{\frac{n+1}{2}+j}).
\]

The claim follows from Propositions 3.2 and 3.3. \(\square\)
The estimate above is based entirely on the size of the integral kernel of $R_0^±(\lambda^2)$ and its derivatives and completely ignores the oscillatory nature of these functions. If one takes advantage of this oscillation using Fourier analysis techniques, the result is a much more subtle mapping estimate known as the Limiting Absorption Principle for the free resolvent (see [Ag, Theorem XIII.33]).

**Lemma 3.5.** Choose any $\sigma, \sigma' > \frac{1}{2}$ and $\varepsilon > 0$. Then for all $\lambda \geq 1$,

$$\|R_0^±(\lambda^2)f\|_{L^{2,-\sigma'}} \lesssim \lambda^{-1+\varepsilon}\|f\|_{L^{2,\sigma}}.$$  

**Sketch of Proof.** First, one shows that (3.2) is a much more subtle mapping estimate known as the Limiting Absorption Principle for the free resolvent (see [Ag], [11, Theorem XIII.33]).

**Remark 3.7.** It is possible to mimic the proof of the Limiting Absorption Principle to prove stronger estimates in the cases where $1 \leq j < \frac{n-1}{2}$. These are interesting in their own right, but will not be needed here.

As mentioned in the introduction, the kernel of the free resolvent is not locally square integrable, which places it outside the context of the mapping estimates above. However, as the next results demonstrate, the kernel associated to $|VR_0^±|^m$ belongs to a weighted $L^2$ space, provided $m$ is big enough and $V$ decays sufficiently rapidly.

We start with the following
Lemma 3.8. Let \( \mu \) and \( \sigma \) be such that \( \mu < n \) and \( n < \sigma + \mu \). Then
\[
\int_{\mathbb{R}^n} \frac{dy}{(y)^n |x-y|^\mu} \lesssim \begin{cases} (x)^{n-\sigma-\mu}, & \sigma < n \\ (x)^{-\mu}, & \sigma > n. \end{cases}
\]

Proof. We analyze the integral on each of the following three disjoint domains:

Domain 1: \( |y| \leq \frac{|x|}{4} \). From the triangle inequality we get \( |x-y| \sim |x| \); we estimate the contribution of this domain to the integral by
\[
|x|^{-\mu} \int_{|y| \leq \frac{|x|}{4}} (y)^{-\sigma} dy \lesssim |x|^{-\mu} |x|^n (x)^{-\sigma} \lesssim \begin{cases} (x)^{n-\sigma-\mu}, & \sigma < n \\ (x)^{-\mu}, & \sigma > n. \end{cases}
\]

Domain 2: \( |x-y| \leq \frac{|x|}{2} \). On this domain \( |y| \sim |x| \) and we estimate its contribution to the integral by
\[
\int_{|x-y| \leq \frac{|x|}{2}} \frac{dy}{(y)^n |x-y|^\mu} = (x)^{-\sigma} \int_0^{\frac{|x|}{2}} r^{n-1} r^\mu dr \lesssim (x)^{n-\sigma-\mu},
\]
where the inequality holds because \( \mu < n \).

Domain 3: \( |y| > \frac{|x|}{4} \) and \( |x-y| > \frac{|x|}{2} \). The triangle inequality yields \( |x-y| \sim |y| \) and as \( n - \sigma - \mu < 0 \), we obtain the estimate
\[
\int_{|y| > \frac{|x|}{4}} (y)^{-\sigma} |y|^{-\mu} dy \lesssim (x)^{n-\sigma-\mu},
\]
by treating \( |x| \leq 1 \) and \( |x| > 1 \) separately. \(\square\)

Proposition 3.9. Suppose \( |V(x)| \leq C|x|^{-\beta} \) for some \( \beta > n + 3 \). Then for any integer \( 0 \leq j \leq \frac{n}{2} + 1 \) and any pair \( (p,q) \) such that either \( 1 < p < \frac{2n}{n+2} \) and \( \frac{1}{q} = \frac{1}{p} - \frac{1}{n+2} \) or \( p = 1 \) and \( 1 \leq q < \frac{n}{n-2} \), we have
\[
\left\| \left( \frac{d}{dx} \right)^j R_0^\beta (\lambda^2) f \right\|_{L^1} \lesssim \lambda^{-j} \langle \lambda \rangle^{j+\frac{2n}{n+2}} \|f\|_{L^1} \cdot \|f\|_{L^p}.
\]

Proof. In view of (3.8), we need only prove estimates for the operator \( V I_k \) for certain \( 2 \leq k \leq n + \frac{n}{2} \).

The weighted \( L^p \) estimate follows from
\[
\sup_{x \in \mathbb{R}^n} (x)^{-\frac{3}{2}} \int_{\mathbb{R}^n} (y)^{\frac{n}{2} - \beta} |x-y|^{k-n} dy \lesssim 1,
\]
which is a direct consequence of Lemma 3.8 with \( \sigma = \beta - \frac{3}{2} \) and \( \mu = n - k \).

We turn now to the smoothing estimate. Consider first the case \( p = 1 \). Lemma 3.8 with \( \sigma = q \beta \) and \( \mu = q(n-k) \) implies that for \( 1 \leq q < \frac{n}{n-2} \), we have
\[
\int |V(x)|^q |x-y|^{q(k-n)} dx \lesssim (y)^{\frac{2n}{n+2}}.
\]
Note that the upper bound on \( q \) is dictated by \( k = 2 \). Thus, in the case \( p = 1 \), the claim follows from Minkowski’s inequality:
\[
\left\| V(x) \int |x-y|^{k-n} f(y) dy \right\|_{L^q} \lesssim \int |f(y)| \langle y \rangle^{\frac{3}{2}} dy \lesssim \|f\|_{L^1},
\]
Lastly, we treat the case \( 1 < p < \frac{2n}{n+3} \). Note that given \( p \), the choice of \( q \) is governed by the Hardy-Littlewood-Sobolev inequality for \( I_2 \). As \( V \in L^\infty \), we obtain
\[
\| V I_2(f) \|_{L^q} \lesssim \|f\|_{L^p} \lesssim \|f\|_{L^1} \cdot \|f\|_{L^{1+\frac{n}{2}} \cap L^p}.
\]
It remains to consider \( I_k \) with \( k = \frac{n+1}{2} + j \). For \( 0 \leq j < \frac{n-1}{2} \), by the Hardy-Littlewood-Sobolev inequality and the fact that \( V \in L^1 \cap L^\infty \), we get
\[
\| V I_{\frac{n+1}{2} + j}(f) \|_{L^q} \lesssim \| V \|_{\frac{2n}{n-1+j}} \| I_{\frac{n+1}{2} + j}(f) \|_{\frac{2n}{n-1+j}} \lesssim \| f \|_{L^p} \lesssim \| f \|_{L^{1,\frac{2}{n+1+j}L^p}}.
\]
For the remaining values of \( j \), i.e., \( \frac{n-1}{2} \leq j < \frac{n}{2} + 1 \), we use again Lemma 3.8 with \( \sigma = q\beta \) and \( \mu = q(n-k) \) to obtain
\[
\int |V(x)|^q |x-y|^{q(k-n)} \, dx \lesssim \langle y \rangle^{\frac{q}{2}}
\]
for \( 1 \leq q < \frac{2n}{n-1} \). For the values of \( p \) currently under consideration, \( q \) is guaranteed to lie in this range. Another application of Minkowski’s inequality yields
\[
\| V I_{\frac{n+1}{2} + j}(f) \|_{L^q} \lesssim \| f \|_{L^{1,\frac{2}{n+1+j}L^p}}.
\]
This completes the proof of the proposition. □

**Proposition 3.10.** For any \( 0 \leq j \leq \frac{n}{2} + 1 \) and \( \sigma > j + \frac{1}{2} \),
\[
\left\| \left( \frac{d}{d\lambda} \right)^j R^\pm_0 (\lambda)^2 f \right\|_{L^{2,- \sigma}} \lesssim \lambda^{-j} \langle \lambda \rangle^{j+\frac{n+1}{2}} \| f \|_{L^{1,\frac{2}{n+1+j}L^2}}.
\]

**Proof.** We use the estimate (3.1) and split the resolvent kernel into two pieces, according to whether \( |x-y| < 1 \) or \( |x-y| \geq 1 \). The piece supported away from the diagonal \( x = y \) maps \( L^1 \) into \( L^{2,-\sigma} \) because of the bound
\[
\sup_{x \in \mathbb{R}^n} \int_{|x-y| \geq 1} \frac{dy}{|x-y|^{2(n-k)} |y|^{2\sigma}} \lesssim 1,
\]
valid for any \( k \leq \frac{n+1}{2} + j \). The piece supported close to the diagonal \( x = y \) is a convolution against an integrable function and hence it maps \( L^2 \) to itself. □

If the map \( VR_0^\pm (\lambda^2) \), or one of its derivatives (with respect to \( \lambda \)), is applied enough times to a locally integrable function with fast decay, the result will be locally in \( L^2 \). Any subsequent applications of the free resolvent will yield functions in weighted \( L^2 \) spaces. Each time the Limiting Absorption Principle is invoked, it improves the norm bounds by a factor of \( \langle \lambda \rangle^{-1+\varepsilon} \) until eventually, some polynomial decay in \( \lambda \) is achieved. Our primary estimate of this form is given below.

**Corollary 3.11.** Suppose \( |V(x)| \leq C \langle x \rangle^{-\beta} \) for some \( \beta > n+3 \). Let \( m_0 > \frac{n^2}{2} \) and \( 0 \leq j \leq \frac{\beta}{2} + 1 \). Then
\[
\left( \frac{d}{d\lambda} \right)^j [VR_0^\pm (\lambda^2)]^{m_0} f \right\|_{L^{2,- \sigma}} \lesssim \lambda^{-j} \langle \lambda \rangle^{j+1-\frac{n}{2}} \| f \|_{L^{1,\frac{2}{\beta}}}.
\]

**Proof.** The lower bound of \( \frac{n^2}{2} \) is not intended to be sharp and was obtained in the following manner: It requires about \( \frac{n}{2} \) iterations of \( VR_0^\pm (\lambda^2) \) to smooth an integrable function to local \( L^2 \) behavior (see Proposition 3.9) and one more to reach a weighted \( L^2 \) space (see Proposition 3.10). Also, \( \frac{n}{2} + 1 \) powers of \( VR_0^\pm (\lambda^2) \) can be lost to derivatives which we bound using Corollary 3.1. For each of these \( \frac{3n+8}{2} \) operations, we have established only a crude bound which grows like \( \lambda^{\frac{n+3}{2}} \). According to Lemma 3.8, each time the Limiting Absorption Principle is invoked, this reduces the degree of polynomial growth by \( 1 - \varepsilon \), so it needs to be done approximately \( \frac{(3n+8)(n-3)}{8} + 2n - 1 \) times. Setting \( m_0 > \frac{n^2}{2} \) is sufficient to obtain (3.3). □
We will also need the following mapping properties of $\text{Im} \, R_0(\lambda^2)$.

**Proposition 3.12.** Let $0 \leq j < \frac{2}{n} + 1$. Then, for $\sigma > \frac{n+3}{2}$ we have

$$\left\| \left( \frac{d}{d\lambda} \right)^j \text{Im} \, R_0(\lambda^2) \right\|_{L^2,\sigma \to L^2, -\sigma} \lesssim \lambda^{n-2-j} \langle \lambda \rangle^{j/2}.$$  

Moreover, assuming $|V(x)| \leq C|x|^{-\beta}$ for some $\beta > n + 3$, we have

$$\left\| \left( \frac{d}{d\lambda} \right)^j V \text{Im} \, R_0(\lambda^2) \right\|_{L^1 \to L^{1+\frac{j}{2}}} \lesssim \lambda^{n-2-j} \langle \lambda \rangle^{j/2}$$

while, for $m \geq 2m_0 > n^2$, $\sigma > \frac{n+3}{2}$, and $\beta > 2\sigma$, we have

$$\left\| \left( \frac{d}{d\lambda} \right)^j \text{Im} \, R_0^m(\lambda^2) \right\|_{L^{1+\frac{j}{2}}} \lesssim \lambda^{n-2-j} \langle \lambda \rangle^{j+\frac{\beta}{2} - 2n + \frac{n^2(n-3)}{4}}.$$  

**Proof.** From (2.33), we have the following formula for the kernel of $\text{Im} \, R_0(\lambda^2)$:

$$\text{Im} \, R_0(\lambda^2)(x, y) = a_{n-2, \frac{n-2}{2}}(\lambda|x-y|) \frac{e^{\pm i\lambda|x-y|}}{|x-y|^{n+1}}.$$  

Derivatives can affect $\text{Im} \, R_0(\lambda^2)$ in two ways: Whenever a derivative falls on the symbol, this has the effect of reducing the power of $\lambda$ by one. If a derivative falls on the phase, this has the effect of increasing the power of $|x-y|$ by one. Hence, using the calculus of the symbols $a_{i,j}$, we get

$$\left( \frac{d}{d\lambda} \right)^j \text{Im} \, R_0(\lambda^2)(x, y) = \sum_{j_1+j_2=j, j_1, j_2 \geq 0} \lambda^{-j_1} a_{n-2, \frac{n-2}{2}}(\lambda|x-y|) \frac{e^{\pm i\lambda|x-y|}}{|x-y|^{n-2-j_2}}$$

$$= \sum_{j_1+j_2=j, j_1, j_2 \geq 0} \lambda^{n-2-j} a_{j_2, j_2 - \frac{n+1}{2}}(\lambda|x-y|) e^{\pm i\lambda|x-y|}.$$  

Thus,

$$\left( \frac{d}{d\lambda} \right)^j \text{Im} \, R_0(\lambda^2)(x, y) \lesssim \lambda^{n-2-j} \langle \lambda |x-y| \rangle^{j-\frac{n+1}{2}}.$$  

The estimate (3.4) follows from (3.7) and

$$\int \frac{\langle y \rangle^{-2\sigma} \langle x \rangle^{-2\sigma}}{(\lambda|x-y|)^{n-1-2j}} dx\, dy \lesssim \langle \lambda \rangle^3.$$  

For $0 \leq j \leq \frac{1}{2}$, (3.8) follows from the bound $\langle \lambda|x-y| \rangle^{-n+1+2j} \lesssim 1$; the resulting integral is finite whenever $\sigma > \frac{3}{2}$. For $\frac{1}{2} < j \leq \frac{2}{n} + 1$, we first apply Lemma 3.8 to the integral in the variable $y$ to obtain

$$\int \frac{\langle y \rangle^{-2\sigma}}{(\lambda|x-y|)^{n-1-2j}} dy \lesssim \lambda^{n+1+2j} \int \frac{\langle y \rangle^{-2\sigma}}{|x-y|^{n-1-2j}} dx\, dy \lesssim \langle \lambda \rangle^3 \langle x \rangle^{-n+1+2j}.$$  

The remaining integral in the variable $x$ is finite under our assumptions on $\sigma$.

In view of (3.7), the estimate (3.9) follows from

$$\sup_{x \in \mathbb{R}^n} \langle x \rangle^{-\frac{3}{2}} \int \frac{\langle y \rangle^{\beta - \frac{3}{2}}}{\langle \lambda|x-y| \rangle^{\beta - \frac{3}{2} - j}} \lesssim 1.$$  

To see (3.9), one considers separately the cases $0 \leq j \leq \frac{1}{2}$ and $\frac{1}{2} < j \leq \frac{2}{n} + 1$, bounding $\langle \lambda|x-y| \rangle^{-\frac{3}{2} + 1+j} \lesssim 1$ in the former case and applying Lemma 3.8 with $\sigma = \beta - \frac{3}{2}$ and $\mu = \frac{n-1}{2} - j$ in the latter case.
We turn now to (3.6). We rewrite \( \text{Im}[VR^+_0(\lambda^2)]^m = [VR^+_0(\lambda^2)]^m - [VR^-_0(\lambda^2)]^m \) using the following algebraic identity:

\[
(3.10) \quad \prod_{k=0}^M A_k^+ - \prod_{k=0}^M A_k^- = \sum_{l=0}^{M} \left( \prod_{k=0}^{l-1} A_k^- \right) \left( \prod_{k=l+1}^M A_k^+ \right).
\]

Then,

\[
(3.11) \quad \text{Im}[VR^+_0(\lambda^2)]^m = \sum_{m_1+m_2=m} [VR^-_0(\lambda^2)]^{m_1} V \text{Im} R_0 [VR^+_0(\lambda^2)]^{m_2}.
\]

We treat the cases \( m_1 < m_0 \) and \( m_2 < m_0 \) separately. In the first case, use Corollary 3.11 for \([VR^-_0(\lambda^2)]^{m_1} \), (3.4), and Corollary 3.13 for \([VR^-_0(\lambda^2)]^{m_1} \) to derive the claim. In the second case, use the weighted \( L^1 \) bound in Proposition 3.9 for \([VR^+_0(\lambda^2)]^{m_2} \), (5.5), and Corollary 3.11 for \([VR^-_0(\lambda^2)]^{m_1} \) to obtain (5.0). \( \square \)

We also record the following lemma whose proof is just an exercise in integration by parts:

**Lemma 3.13.** Given \( a \in C^\infty_c(\mathbb{R} \setminus \{0\}) \), we have

\[
\left| \int_0^\infty e^{it\lambda^2} \lambda a(\lambda) d\lambda \right| \lesssim |t|^{-N} \sum_{s=0}^N \int_\mathbb{R} e^{it\lambda^2} \lambda^{s+1-2N} a^{(s)}(\lambda) d\lambda,
\]

for every \( N \geq 0 \).

4. **Dispersive Estimate for the Final Term**

In this section we will show that the tail (2.4) of the finite Born series expansion (2.3) obeys dispersive estimates for any potential \( V(x) \) satisfying \( |V(x)| \lesssim \langle x \rangle^{-\beta} \), provided we take \( \beta \) and \( m \) large enough.

**Theorem 4.1.** Assume that the potential \( V \) satisfies \( |V(x)| \lesssim \langle x \rangle^{-\beta} \) for some \( \beta > \frac{3\alpha+\frac{5}{2}}{2} \) and that \( m > n^2 \). Then

\[
\sup_{x,y \in \mathbb{R}^3} \left| \int_0^\infty e^{it\lambda^2} \lambda \left\{ R^+_0(\lambda^2) V R^+_0(\lambda^2)^m S^+(\lambda^2) R^+_0(\lambda^2) \right\} (x,y) d\lambda \right| \lesssim |t|^{-\frac{5}{2}}.
\]

**Remark 4.2.** The condition \( \beta > \frac{3\alpha+\frac{5}{2}}{2} \) is not intended to be sharp. Since the function we eventually construct as a counterexample has compact support, decay conditions are not a matter of primary concern.

There are numerous oscillatory components in this integral, which suggests the use of stationary phase methods. Although it appears natural to take the critical point to be \( \lambda = 0 \), this turns out not to be the best choice. Define the functions \( G_{\pm,x}(\lambda^2)(\cdot) := e^{\mp \lambda |x|} R^\pm_0(\lambda^2)(\cdot, x) \). The expression in (4.1) can be rewritten as

\[
I^+(t,x,y) - I^-(t,x,y),
\]

where

\[
I^\pm(t,x,y) := \int_0^\infty e^{it\lambda^2} e^{\pm \lambda (|x| + |y|)} \lambda \langle S^\pm(\lambda^2) R^\pm_0(\lambda^2) [VR^\pm_0(\lambda^2)]^m V G_{\mp,y}(\lambda^2), [VR^\mp_0(\lambda^2)]^m V G_{\mp,x}(\lambda^2) \rangle d\lambda
\]

\[
= \int_0^\infty e^{it\lambda^2} e^{\pm i\lambda (|x| + |y|)} b^\pm_{x,y}(\lambda^2) d\lambda.
\]
It suffices to show that \(|I^+(t, x, y) - I^-(t, x, y)| \lesssim |t|^{-\frac{\sigma}{2}}\) uniformly in \(x\) and \(y\).

The first step is to establish some properties (including existence) of the operators \(S^\pm(\lambda^2)\). This is the crux of the Limiting Absorption Principle for perturbed resolvents. We sketch the details below.

**Proposition 4.3.** Suppose \(|V(x)| \leq C(x)^{-\beta}\) for some \(\beta > \frac{n+1}{2}\) and also that zero energy is neither an eigenvalue nor a resonance of \(H = -\Delta + V\). Then

\[
\sup_{\lambda \geq 0} \|S^\pm(\lambda^2)\|_{L^2(\sigma \to L^2,-\sigma)} < \infty
\]

for all \(\sigma \in \left(\frac{1}{2}, \beta - \frac{1}{2}\right)\).

**Proof.** Under our assumptions, \(\overset{\circ}{\text{Lemma 3.3}}\) and Proposition \(\overset{\circ}{\text{3.2}}\) imply that \(R^\pm_0(\lambda^2)V\) is a compact operator on the space \(L^2(\sigma)\). The Fredholm alternative then guarantees the existence of \(S^\pm(\lambda^2)\) unless there exists a nonzero function \(g \in L^2(\sigma)\) satisfying \(g = -R^\pm_0(\lambda^2)Vg\).

For \(\lambda > 0\), as \(g = -R^\pm_0(\lambda^2)Vg\) is formally equivalent to \((-\Delta + V)g = \lambda^2g\), it follows by a theorem of Agmon \(\overset{\circ}{\text{[Ag]}}\) (see also \(\overset{\circ}{\text{[10, Section XIII.8]}}\)) that \(g\) is in fact an eigenfunction, that is, \(g \in L^2\). As positive imbedded eigenvalues do not exist by Kato’s theorem (see, for example, \(\overset{\circ}{\text{[10, Section XIII.8]}}\)), we must have \(g \equiv 0\).

When \(\lambda = 0\), the free resolvent \(R_0(0)\) is a scalar multiple of \(I_2\). Since we are in dimension \(n \geq 4\), it is possible to improve the decay of \(g\) by a bootstrap argument to obtain \(g \in L^2(\sigma)\) for all \(\sigma' > 0\); in dimension \(n \geq 5\), it is in fact possible to bootstrap all the way to \(g \in L^2\). In other words, zero energy would have to be either an eigenvalue or a resonance of \(H\), contradicting our assumptions. Thus, we must have \(g \equiv 0\).

To obtain a uniform bound for \(S^\pm(\lambda^2)\), note that by \(\overset{\circ}{\text{Lemma 3.3}}\) we have

\[
\|R^\pm_0(\lambda^2)V\|_{L^2(\sigma \to L^2,-\sigma)} \lesssim \langle \lambda \rangle^{-1+\varepsilon}.
\]

Thus \(I + R^\pm_0(\lambda^2)V\) converges to the identity as \(\lambda \to \infty\). Its inverse, \(S^\pm(\lambda^2)\), will thus have operator norm less than 2 for all \(\lambda > \lambda_0\). On the remaining interval, \(\lambda \in [0, \lambda_0]\), observe that the family of operators \(R^\pm_0(\lambda^2)\) varies continuously with \(\lambda\). By continuity of inverses, \(S^\pm(\lambda^2)\) is continuous and bounded on this compact interval. \(\square\)

Derivatives of \(S^\pm(\lambda^2)\) can be taken using the identity

\[
\frac{d}{d\lambda} S^\pm(\lambda^2) = -S^\pm(\lambda^2) \frac{d}{d\lambda} \left(R^\pm_0(\lambda^2)\right) V S^\pm(\lambda^2).
\]

From this, Corollary \(\overset{\circ}{\text{3.3}}\) and Proposition \(\overset{\circ}{\text{3.8}}\) it follows that for \(1 \leq j \leq \frac{1}{2} + 1\).

\[
(4.3) \quad \left\| \left(\frac{d}{d\lambda}\right)^j S^\pm(\lambda^2) \right\|_{L^2(\sigma \to L^2,-\sigma)} \lesssim \lambda^{-j} \langle \lambda \rangle^{j+\frac{n-3}{2}},
\]

provided \(\frac{1}{2} + j < \sigma < \beta - (\frac{1}{2} + j)\) and \(\beta > \frac{n+1}{2} + j\). Moreover, it becomes clear that \(R^\pm_0(\lambda^2) = S^\pm(\lambda^2)R^\pm_0(\lambda^2)\) and its derivatives have mapping properties comparable to those of the free resolvent.

We now have estimates for every object in \(\overset{\circ}{\text{12}}\) except for the functions \(G_{\pm,0}(\lambda^2)\). These follow from another straightforward computation.
Proposition 4.4. Suppose $|V(x)| \leq C(x)^{-\beta}$ for some $\beta > \frac{3n+5}{2}$. Then for each $0 \leq j \leq \frac{n}{2} + 1$,

\begin{equation}
(4.4) \quad \left\| V(\frac{d}{dx})^j G_{\pm,y}(\lambda^2)(\cdot) \right\|_{L^1 \frac{2}{n+1}} \lesssim \frac{\lambda^{-j}}{(y)^{n-2}} + \frac{\lambda^{\frac{n+3-j}{2}}}{(y)^{\frac{n}{2} + j}} + \frac{\lambda^{\frac{n+3}{2}}}{(y)^{\frac{n}{2} + j}}.
\end{equation}

Proof. Write out the function $G_{\pm,y}(\lambda^2)$ in the form

$$G_{\pm,y}(\lambda^2)(x) = a_0 \rho_n \rho_\lambda (\lambda |x-y|) e^{\pm i\lambda (|x-y|-y)}.$$ 

Derivatives can affect $G_{\pm,y}$ in one of two ways. Whenever a derivative falls on the symbol, it has the effect of reducing the power of $\lambda$ by one (this property was utilized previously in Section 3). When derivatives fall on the exponential factor, the effect is to multiply by $|x-y|-\langle y \rangle$, which is smaller than $\langle x \rangle$. Thus, for $0 \leq j \leq \frac{n}{2} + 1$,

$$\left\| (\frac{d}{dx})^j G_{\pm,y}(\lambda^2)(x) \right\| \lesssim \sum_{j_1 + j_2 = j} \lambda^{j_1} a_0 \rho_n \rho_\lambda (\lambda |x-y|) \frac{(|x-y|-\langle y \rangle)^{j_2}}{|x-y|^{n-2}} e^{\pm i\lambda (|x-y|-y)}$$

and hence

$$\left\| (\frac{d}{dx})^j G_{\pm,y}(\lambda^2)(x) \right\| \lesssim \sum_{j_1 + j_2 = j} \left( \lambda^{j_1} \frac{\langle x \rangle^{j_2}}{|x-y|^{n-2}} + \lambda^{\frac{n+3}{2} - j_1} \frac{\langle x \rangle^{j_2}}{|x-y|^{\frac{n}{2} + j_2}} \right).$$

The result now follows from Lemma 3.8 provided $\beta > \frac{3n+5}{2}$.

Proof of Theorem 4.1. Consider first what happens if $|t| \leq 4$. The bounds established in Corollary 3.11 (for $j = 0$), Proposition 4.3 and Proposition 4.4 (for $j = 0$) show that the function $b^\pm_{\epsilon, y}(\lambda^2)$ in (4.2) is smaller than $\langle \lambda \rangle^{-2}$ uniformly in $x$ and $y$. This bounds the value of $I^+(t, x, y) - I^-(t, x, y)$ by a constant, which is less than $|t|^{-\frac{n}{2}}$ as desired.

For the remainder of the calculation we will assume that $|t| > 4$.

Let $\rho : \mathbb{R} \to \mathbb{R}$ be a smooth even cutoff function which is identically one on the interval $[-1, 1]$ and identically zero outside $[-2, 2]$. Let $b^\pm_{x,y,1}(\lambda^2) := \rho(|t|^2 \lambda) b^\pm_{x,y}(\lambda^2)$ and $b^\pm_{x,y,2} := b^\pm_{x,y} - b^\pm_{x,y,1}$ and define $I^\pm_1(t, x, y)$ and $I^\pm_2(t, x, y)$ accordingly. By simplicity, the dependence on $x$ and $y$ will be suppressed whenever possible.

We consider the integrals $I^\pm_2(t, x, y)$ first.

Case 1: $|x| + |y| \geq |t|$. At least one of $|x|$, $|y|$ is greater than $\frac{|t|}{2}$; without loss of generality assume it is $|y|$. Then $|y|^{-1} \leq 2|t|^{-1} < |t|^{-\frac{n}{2}}$ and hence $|y|^{-1}$ does not belong to supp $b^\pm_{2}$. Moreover, for $\lambda \geq |y|^{-1}$, Proposition 4.4 yields the bound

\begin{equation}
(4.5) \quad \| V(\frac{d}{dx})^j G_{\pm,y}(\lambda^2) \|_{L^1 \frac{2}{n+1}} \lesssim \frac{\lambda^{\frac{n+3}{2} - j} \langle \lambda \rangle^j}{(y)^{\frac{n}{2} + j}} \lesssim |t|^{\frac{n+3}{2}} \lambda^{\frac{n+3}{2} - j} \langle \lambda \rangle^j.
\end{equation}

To bound $G_{\pm,x}(\lambda^2)$, we use

\begin{equation}
(4.6) \quad \| V(\frac{d}{dx})^j G_{\pm,x}(\lambda^2) \|_{L^1 \frac{2}{n+1}} \lesssim \lambda^{-j} \langle \lambda \rangle^{j + \frac{n}{2} - 1}.
\end{equation}

No additional improvement can be gained here, because the size of $|x|$ is unknown.

By Corollary 3.3, Corollary 3.11, Proposition 4.3, (4.3), (4.5), and (4.6), we can deduce

$$|b^\pm_{2}(\lambda^2)| \lesssim |t|^{\frac{n+3}{2}} \lambda^{\frac{n+3}{2} - 3n - 1} \lesssim |t|^{\frac{n+3}{2}} \langle \lambda \rangle^{-\frac{5n+5}{2}}.$$
and
\[ \left| \frac{d}{d\lambda} b^\pm_2(\lambda^2) \right| \lesssim |t|^{\frac{n-1}{2n}} \lambda^{\frac{n-1}{2n}} \langle \lambda \rangle - \frac{n+1}{2n} \langle \lambda \rangle. \]

Applying stationary phase around the critical point \( \lambda_0 = \mp \frac{|x|+|y|}{2t} \) and integrating by parts once away from the critical point, it follows that \( |I_2^\pm(t)| \lesssim |t|^{-\frac{3}{2}}. \)

**Case 2:** \( |t|^{\frac{3}{2}} \leq |x| + |y| < |t|. \) Again, assume without loss of generality that \( |y| \geq \frac{1}{2}|t|^\frac{3}{2}. \) Therefore, for \( \lambda \in \text{supp} \ b^\pm_2 \) we have \( |y| \geq \frac{1}{2}|\lambda|^{-1} \), which implies
\[ \| V \left( \frac{d}{d\lambda} \right)^j G_{\pm, y}(\lambda^2) \|_{L^{1, \frac{4}{3}}} \lesssim \frac{\lambda^{\frac{n-1}{2n}} \langle \lambda \rangle^{j-n/(n+1)} \langle y \rangle^{-\frac{n}{2}}} \]

For \( G_{\pm, x}(\lambda^2) \) we will use (4.6).

The critical point for the phase occurs at \( \lambda_0 = \mp \frac{|x|+|y|}{2t} \), which is comparable in size to \( \frac{|x|+|y|}{|t|} \) and greater than \( \frac{1}{2}|t|^{-\frac{3}{2}}. \) In the interval \( [\lambda_0 - \frac{1}{2}|t|^{-\frac{3}{2}}, \lambda_0 + \frac{1}{2}|t|^{-\frac{3}{2}}] \) we have the size estimate
\[ |b^\pm_2(\lambda^2)| \sim \left( \frac{|\lambda_0|}{|y|} \right)^{\frac{n-1}{n}} \sim |t|^{-\frac{n}{2}+\frac{1}{2}}. \]

An application of stationary phase yields the desired bound on this interval.

Away from the critical point, the derivatives of \( b^\pm_2(\lambda^2) \) obey the following bounds

(4.7)
\[ \left| \left( \frac{d}{d\lambda} \right)^j b^\pm_2(\lambda^2) \right| \lesssim \frac{\lambda^{\frac{n-1}{2n}} \langle \lambda \rangle^{-\frac{2(n+1)}{n+1}} \langle y \rangle^{-\frac{n}{2}}} \]

for all \( 0 \leq j \leq \frac{n}{2} + 1. \)

Over the intervals \( [|t|^{-\frac{3}{2}}, \lambda_0 - \frac{1}{2}|t|^{-\frac{3}{2}}] \) and \( [\lambda_0 + \frac{1}{2}|t|^{-\frac{3}{2}}, 2\lambda_0] \), (4.7) becomes
\[ \left| \left( \frac{d}{d\lambda} \right)^j b^\pm_2(\lambda^2) \right| \lesssim \frac{\lambda^{\frac{n-1}{2n}} \langle \lambda \rangle^{-\frac{2(n+1)}{n+1}} \langle y \rangle^{-\frac{n}{2}}} \]

for all \( 0 \leq j \leq \frac{n}{2} + 1. \) As on this region \( \lambda - \lambda_0 \gtrsim |t|^{-\frac{3}{2}}, \) each integration by parts in (4.7) gains us a factor of \( |t|^{-\frac{3}{2}}. \) Thus, integrating by parts twice (i.e., taking \( j = 2 \) and recalling that in this case \( \lambda_0 \gtrsim |t|^{-\frac{3}{2}}, \) we obtain the desired dispersive estimate.

Over the interval \( [2\lambda_0, 1] \) (where \( \lambda - \lambda_0 \gtrsim \frac{1}{2}|t|^{\frac{3}{2}} \)), we use (4.7) and the assumption \( |y| \geq \frac{1}{2}|t|^{\frac{3}{2}} \) to get
\[ \left| \left( \frac{d}{d\lambda} \right)^j b^\pm_2(\lambda^2) \right| \lesssim \lambda^{\frac{n-1}{2n}} \langle \lambda \rangle^{-\frac{2(n+1)}{n+1}} |t|^{-\frac{n-1}{2}} \]

for all \( 0 \leq j \leq \frac{n}{2} + 1. \) To obtain the desired decay in \( t, \) it is necessary to integrate by parts at least \( \frac{n+1}{2} \) times.

On the interval \( [1, \infty], \) (4.7) implies that \( b^\pm_2(\lambda^2) \) and its derivatives all decay faster than \( \langle \lambda \rangle^{-2} \langle y \rangle^{-\frac{n}{2}} \). Using again the assumption \( |y| \geq \frac{1}{2}|t|^{\frac{3}{2}} \) and integrating by parts another \( \frac{n+1}{2} \) times, we obtain the desired dispersive estimate.

**Case 3:** \( |x|, |y| < |t|^{\frac{3}{2}}. \) This time, the critical point \( \lambda_0 = \mp \frac{|x|+|y|}{2t} \) lies outside the support of \( b^\pm_2(\lambda^2). \) Therefore, one could safely integrate by parts; however, the lack
of a lower bound for $|x|$ and $|y|$ limits the usefulness of estimates like (4.3) in the regime $\lambda < 1$. Without loss of generality, assume $|y| \geq |x|$.

For $\lambda > 1$, $b^2_0(2\lambda^2)$ and its derivatives decay rapidly. Indeed, by Corollary 3.11, Proposition 4.3, (4.3), and Proposition 4.4, for $\lambda \geq 1$ and $0 \leq j \leq \frac{n}{2} + 1$ we get

$$\left| \left( \frac{d}{d\lambda} \right)^j b_2^{+} (\lambda^2) \right| \lesssim \lambda^{-2n-3} \left( \frac{1}{\langle x \rangle^{n-2}} + \frac{1}{\langle y \rangle^{n-2}} \right) \left( \frac{1}{\langle x \rangle^{n-2}} + \frac{1}{\langle y \rangle^{n-2}} \right).$$

As the powers of $\langle x \rangle$ and $\langle y \rangle$ in the denominator may not make a meaningful contribution (if $x,y$ are small), it is necessary to integrate by parts at least $\frac{n}{2}$ times in order to generate the desired $|t|^{-\frac{n}{2}}$ decay or better.

The regime $\lambda \in [\langle y \rangle^{-1}, 1]$ is similar to the interval $[2\lambda_0, 1]$ in the previous case. Indeed,

$$\| V (\frac{d}{d\lambda})^j G_{\pm, y}(\lambda^2) \|_{L^1, \frac{1}{2}} \lesssim \frac{\lambda^{\frac{n}{2} - j} \langle \lambda \rangle^j}{\langle y \rangle^{\frac{n}{2}}} \lesssim \frac{\lambda^{\frac{n}{2} - j}}{\langle y \rangle^{\frac{n}{2}}},$$

and

$$\| V (\frac{d}{d\lambda})^j G_{\pm, x}(\lambda^2) \|_{L^1, \frac{1}{2}} \lesssim \langle \lambda \rangle^{-j} \langle \lambda \rangle^{j+\frac{n}{2} - 2} \lesssim \langle \lambda \rangle^{-j}$$

for all $0 \leq j \leq \frac{n}{2} + 1$. Thus,

$$\left| \left( \frac{d}{d\lambda} \right)^j b_2^{+} (\lambda^2) \right| \lesssim \frac{\lambda^{\frac{n}{2} - j} \langle \lambda \rangle^j}{\langle y \rangle^{\frac{n}{2}}} \lesssim \frac{\lambda^{\frac{n}{2} - j}}{\langle y \rangle^{\frac{n}{2}}}$$

for all $0 \leq j \leq \frac{n}{2} + 1$. Integrating by parts $\frac{n}{2} \leq N \leq \frac{n}{2} + 1$ times is more than enough to create polynomial decay in $\lambda$:

$$|t|^{-N} \int_{\langle y \rangle^{-1}}^{1} (\lambda - \lambda_0)^{-N} \frac{\lambda^{\frac{n}{2} - N}}{\langle y \rangle^{\frac{n}{2}}} d\lambda \lesssim |t|^{-N} \langle y \rangle^{2N-n}.$$

Recalling that in this case we have $|y| < |t|^{\frac{1}{4}}$, the resulting bound for this piece is $|t|^{-\frac{n}{2}}$.

For the remaining interval, $[|t|^{-\frac{1}{4}}, \langle y \rangle^{-1}]$, we exploit instead the cancellation between $R_0^+(\lambda^2)$ and $R_0^-(\lambda^2)$ using the algebraic identity (3.10). We apply (3.10) to $I_2^+(t,x,y) - I_2^-(t,x,y)$, where

$$I_2^+(t,x,y) = \int_0^\infty e^{it\lambda^2} (1 - \rho(|t|^{\frac{1}{4}}\lambda)) \lambda \{ R_0^+(\lambda^2) V [R_0^+(\lambda^2) V]^m S^+(\lambda^2) R_0^+(\lambda^2) \} \times [VR_0^+(\lambda^2)]^m VR_0^+(\lambda^2) d\lambda$$

$$= \int_0^\infty e^{it\lambda^2} (1 - \rho(|t|^{\frac{1}{4}}\lambda)) \lambda \{ R_0^+(\lambda^2) V [R_0^+(\lambda^2) V]^m S^+(\lambda^2), R_0^+(\lambda^2) \} \times [VR_0^+(\lambda^2)]^m VR_0^+(\lambda^2) d\lambda$$

$$= \int_0^\infty e^{it\lambda^2} c_{x,y,z}^+(\lambda^2) d\lambda.$$

Each term in the resulting sum contains a factor of $R_0^+(\lambda^2) - R_0^-(\lambda^2)$, an integral operator whose kernel is pointwise dominated by $\lambda^{n-2}$ (see (3.7)). This is even true if the cancellation falls on $S^+(\lambda^2)$ because we can write

$$S^+(\lambda^2) - S^-(\lambda^2) = -S^-(\lambda^2)(R_0^+(\lambda^2) - R_0^-(\lambda^2)) V S^+(\lambda^2).$$
We will integrate by parts \( \frac{n+1}{2} \) times if \( n \) is odd and \( \frac{n}{2} + 1 \) times if \( n \) is even. Our analysis relies on the estimates of Proposition 3.12.

In place of the weighted \( L^1 \) estimate (4.4), we use the following two bounds for the two possible initial functions on which the resolvents act. For \( 0 \leq j \leq \frac{n}{2} + 1 \), we have

\[
(4.8) \quad \left\| V(\cdot) \left( \frac{d}{d\lambda} \right)^j R_0^\pm(\lambda^2)(\cdot, y) \right\|_{L^{1, \frac{2}{3}}} \lesssim \frac{\lambda^{-j}}{\langle y \rangle^{n-2}},
\]

\[
(4.9) \quad \left\| V(\cdot) \left( \frac{d}{d\lambda} \right)^j (\text{Im } R_0(\lambda^2))(\cdot, y) \right\|_{L^{1, \frac{2}{3}}} \lesssim \lambda^{n-2-j}.
\]

To see (4.8), we use the pointwise bound

\[
\left| \left( \frac{d}{d\lambda} \right)^j R_0^\pm(\lambda^2)(x, y) \right| \lesssim \lambda^{-j} I_2 + \lambda^{\frac{n-3}{2}} I_{2, n-1+j},
\]

and apply Lemma 3.8 to obtain

\[
\left\| V(\cdot) \left( \frac{d}{d\lambda} \right)^j R_0^\pm(\lambda^2)(\cdot, y) \right\|_{L^{1, \frac{2}{3}}} \lesssim \frac{\lambda^{-j}}{\langle y \rangle^{n-2}} + \frac{\lambda^{\frac{n-3}{2}}}{\langle y \rangle^{n-2}} \lesssim \frac{\lambda^{-j}}{\langle y \rangle^{n-2}},
\]

where the last inequality holds for \( \lambda \leq \langle y \rangle^{-1} \).

Similarly, to prove (4.9) we use (3.4); applying Lemma 3.8 and treating the cases \( 0 \leq j \leq \frac{n-1}{2} \) and \( \frac{n-1}{2} < j \leq \frac{n}{2} + 1 \) separately, we obtain

\[
\left\| V(\cdot) \left( \frac{d}{d\lambda} \right)^j (\text{Im } R_0(\lambda^2))(\cdot, y) \right\|_{L^{1, \frac{2}{3}}} \lesssim \lambda^{n-2-j} (1 + \lambda^\frac{2}{3}(\langle y \rangle^2)) \lesssim \lambda^{n-2-j},
\]

again, for \( \lambda \leq \langle y \rangle^{-1} \).

Using the estimates in Proposition 3.12, (4.8), and (4.9), we get

\[
\left| \left( \frac{d}{d\lambda} \right)^j (c^+_{x,y,2}(\lambda^2) - c^-_{x,y,2}(\lambda^2)) \right| \lesssim \frac{\lambda^{n-1-j}}{\langle y \rangle^{n-2}}.
\]

Thus, an application of Lemma 3.8 with \( N = \frac{n+1}{2} \) for \( n \) odd, or \( N = \frac{n}{2} + 1 \) for \( n \) even yields the bound

\[
|t|^N \int_{|t|^{-\frac{1}{2}}}^{\langle y \rangle^{-1}} \frac{\lambda^{n-1-2N}}{\langle y \rangle^{n-2}} d\lambda \lesssim |t|^{-\frac{n}{2}}.
\]

In each of the three cases discussed above, the difference \( I_1^+(t, x, y) - I_1^-(t, x, y) \) is seen to be smaller than \( |t|^{-\frac{n}{2}} \).

To complete the proof of the theorem, we need to show

\[
|I_1^+(t, x, y) - I_1^-(t, x, y)| \lesssim |t|^{-\frac{n}{2}} \quad \text{for} \quad |t| > 4.
\]

Here,

\[
I_1^+(t, x, y) = \int_0^\infty e^{it\lambda^2} \rho(|t|^{\frac{1}{2}}\lambda^2) \lambda \left\{ R_0^+(\lambda^2) V[R_0^+(\lambda^2) V]^{m} S^+(\lambda^2) R_0^+(\lambda^2) \right\} \times \left[ VR_0^+(\lambda^2) \right]^{m} V R_0^+(\lambda^2) d\lambda,
\]

\[
I_1^-(t, x, y) = \int_0^\infty e^{it\lambda^2} \rho(|t|^{\frac{1}{2}}\lambda^2) \lambda \langle \delta_x, R_0^+(\lambda^2) V[R_0^+(\lambda^2) V]^{m} S^+(\lambda^2) R_0^+(\lambda^2) \rangle \times \left[ VR_0^+(\lambda^2) \right]^{m} V R_0^+(\lambda^2) \delta_x d\lambda,
\]

\[
= \int_0^\infty e^{it\lambda^2} \rho(|t|^{\frac{1}{2}}\lambda^2) \lambda \left\{ R_0^+ c^+_{x,y,1}(\lambda^2) \right\} \times \left[ VR_0^+(\lambda^2) \right]^{m} V R_0^+(\lambda^2) \lambda d\lambda.
\]

Arguing as in Case 3 above, we see that
\[ |c^+_{x,y,1}(\lambda^2) - c^-_{x,y,1}(\lambda^2)| \lesssim \lambda^{n-1}. \]
Thus,
\[ |I^+_1(t, x, y) - I^-_1(t, x, y)| \lesssim \int_0^{|t|^{-\frac{1}{2}}} \lambda^{n-2} d\lambda \lesssim |t|^{-\frac{3}{2}}. \]
This concludes the proof of Theorem 4.1. \( \square \)

5. Nondispersive Estimates

5.1. Nondispersive estimate for the term \( l = 1 \). To summarize the progress up to this point, we have decomposed the perturbed resolvent \( R^\pm_\lambda(\lambda^2) \) into a finite Born series with initial terms given by (2.6) and a tail given by (2.7). In the previous sections, the contribution of the tail was shown to satisfy a dispersive estimate at both high and low energies. The dispersive behavior of the full evolution \( e^{itH} P_\alpha(H) \) is therefore dictated by the contribution from the initial terms of the Born series.

We show that there are potentials in the class
\[ X = \left\{ V \in C^n(\mathbb{R}^n), \quad \alpha < \frac{\lambda + 3}{2}, \quad \text{supp} V \subset B(0, 5) \setminus B(0, 5) \right\} \]
that do not yield a dispersive estimate for the term corresponding to \( l = 1 \) in (2.6). It will follow, via an argument in the next subsection, that the entire expression (2.6) cannot satisfy a dispersive estimate either. To define the class of potentials more precisely, let \( X \) be the completion of the appropriately supported \( C^\infty \) functions with respect to the \( W^\alpha,\infty \)-norm,
\[ \|f\|_X := \|(1 + \Delta)^{\alpha/2}f\|_\infty. \]

Fix the points \( x_0, y_0 \in \mathbb{R}^n \) so that \( x_0 \) is the unit vector in the first coordinate direction and \( y_0 = -x_0 \). Now let \( f^\pm \) and \( g^\pm \) be smooth approximations of \( f = \delta_{x_0} \) and \( g = \delta_{y_0} \) which are supported in \( B(x_0, \varepsilon) \) and \( B(y_0, \varepsilon) \), respectively, and have unit \( L^1 \)-norm. Define the expression
\[
\begin{align*}
\alpha^+_1(t, \varepsilon, V) := & t^{\frac{1}{2}} \int e^{it\lambda} \psi_L(\lambda) \langle R^+_0(\lambda)(x_1, y)V(x_1)|R^+_0(\lambda)(x_1, y) \rangle x dx dy d\lambda \\
= & t^{\frac{1}{2}} \int I^+_1(t, |x - x_1|, |y - x_1|) V(x_1) f^+(x) g^-(y) dx dy d\lambda
\end{align*}
\]
where \( \psi \) can be any Schwartz function with \( \psi(0) = 1 \) and \( \psi_L(\lambda) = \psi(\lambda/L) \). Fubini’s theorem is used to perform the \( d\lambda \) integral first, noting that since \( f^\pm, g^\pm \), and \( V \) all have disjoint support, the singularities of \( R^+_0(\lambda)(x_1, y) \) and \( R^+_0(\lambda)(x_1, y) \) can be disregarded.

If the term corresponding to \( l = 1 \) in the Born series (2.6) satisfied a dispersive estimate, it would yield the bound
\[ \lim_{L \to \infty} |\alpha^+_1(t, \varepsilon, V)| \leq C(V) \|f^\pm\|_1 \|g^\pm\|_1 = C(V). \]
Observe that \( \alpha^+_1(t, \varepsilon, V) \) is linear in the last entry and can therefore be viewed as a family of linear maps indexed by the remaining parameters \( (L, t, \varepsilon) \). By the
Uniform Boundedness Principle, if a dispersive estimate for the $l = 1$ term held for every potential $V \in X$, it would imply the sharper inequality
\begin{equation}
\sup_{L \geq 1} |a_L^t(t, \varepsilon, V)| \leq C \|V\|_X.
\end{equation}

For $t \ll 1$ this will not be possible, thanks to the asymptotic description of the function $I_L(t, |x - x_1|, |y - x_1|)$ stated below.

**Lemma 5.1.** Suppose $n \geq 3$ and $0 < t \leq 1$. Let $\psi : \mathbb{R} \to \mathbb{R}$ be a Schwartz function with Fourier transform supported in the unit interval and satisfying $\psi(0) = 1$, and $K$ a compact subset of $(0, \infty)$. There exist constants $C_1, C_2 < \infty$ depending on $n$, $\psi$, and $K$ such that
\begin{equation}
|I_L(t, |x - x_1|, |x_1 - y|) - \frac{i}{2(-4\pi i)^{n-\frac{2}{3}}} \left( \frac{(|x-x_1|+|x_1-y|)^{n-2}}{|x-x_1| |x_1-y|^{\frac{n-2}{2}}} e^{-i \frac{(|x-x_1|+|x_1-y|)^2}{4t}} \right) | \leq C_1 t^{-n(\frac{1}{2})}
\end{equation}
for all $L > C_2 t^{-3}$ and $|x - x_1|, |x_1 - y| \in K$. If $t$ is held fixed, then the remainder converges as $L \to \infty$ to a function $G(|x - x_1|, |x_1 - y|, t)$ uniformly over all pairs of distances $|x - x_1|, |x_1 - y| \in K$.

The proof of Lemma 5.1 is technical and is given in Section 6 below. An immediate consequence of this lemma is the following

**Corollary 5.2.** Let $n \geq 3$, $0 < t \leq 1$, and $\varepsilon < \frac{1}{2}$. The following bound is valid for all functions $V \in X$ with $\|V\|_X \leq 1$:
\begin{equation}
\lim_{L \to \infty} |a_L^t(t, \varepsilon, V) - \frac{i L^{\frac{3-n}{2}}}{(-4\pi i)^{n-\frac{2}{3}}} \int \left( \frac{(|x-x_1|+|x_1-y|)^{n-2}}{|x-x_1| |x_1-y|^{\frac{n-2}{2}}} \right) e^{-i \frac{(|x-x_1|+|x_1-y|)^2}{4t}} V(x_1) f(x) g(y) dx_1 dy | \leq C L^{\frac{3-n}{2}} \|f\|_1 \|g\|_1.
\end{equation}

**Proof.** If $\varepsilon < \frac{1}{2}$, then we have $|x - x_1|, |x_1 - y| \in [1, 10]$ for every combination of points with $x \in \text{supp}(f^\varepsilon)$, $y \in \text{supp}(g^\varepsilon)$, $x_1 \in \text{supp}(V)$. Thus the conditions of Lemma 5.1 are satisfied, with the conclusion that $I_L(t, \cdot, \cdot)$ converges uniformly as $L \to \infty$ to a bounded function in $x, x_1, y$.

The result then follows from the dominated convergence theorem and the observation that $\|V\|_1 \leq C \|V\|_X \leq C$.

If the integral in (5.4) were taken in absolute values, the resulting bound on $a_L^t(t, \varepsilon, V)$ would be of size $|t|^{\frac{3-n}{2}}$. In dimension $n \geq 4$, this contrasts with the desired estimate
\begin{equation}
\lim_{L \to \infty} |a_L^t(t, \varepsilon, V)| \leq C,
\end{equation}
which is uniform in $t$. Furthermore, for a fixed small time $t$ it is not difficult to construct a potential $V_t \in X$ which negates the oscillatory factor of $e^{-i (|x-x_1|+|x_1-y|)^2/(4t)}$.

Let $\phi$ be a smooth cutoff which is supported in the interval $[6, 8]$ and $F : \mathbb{R} \to \mathbb{R}$ a nonnegative smooth function which satisfies $F(s) = 0$ for all $s \leq 0$ and $F(s) = s$ for all $s \geq \frac{1}{2}$. Given a time $0 < t \leq 1$, define
\begin{equation}
V_t(x_1) = C_n t^{\alpha} \phi(|x_0 - x_1| + |x_1 - y_0|) F \left( \frac{(|x_0 - x_1| + |x_1 - y_0|)^2}{4t} \right).
\end{equation}
The constant $C_n$ will be chosen momentarily. It is perhaps unnecessary to modify
the cosine function with $F$; however, the positivity of $F$ does guarantee that zero
energy will be neither an eigenvalue nor a resonance of $-\Delta + V_t$.

**Proposition 5.3.** There exists a constant $C_n > 0$ so that the function $V_t$ defined
above satisfies $\|V_t\|_X \leq 1$ for all $0 < t \leq 1$.

*Proof.* It is equivalent to show that in the absence of the coefficient $C_n$, $\|V_t\|_X$
would be bounded by a finite constant uniformly in $t$.

The support of $\phi(|x_0 - x_1| + |x_1 - y_0|)$ is located within an annular region bounded
by the ellipsoids with foci $x_0, y_1$ and major axes of length 6 and 8, respectively. As
this region is bounded away from both $x_0$ and $y_0$, the length sum $|x_0 - x_1| + |x_1 - y_0|$
is a scalar $C^\infty$-function of $x_1$.

It follows that any sufficiently smooth function of $\frac{|x_0 - x_1| + |x_1 - y_0|}{4t}$
on this domain should have $C^n$-norm controlled by $(1 + t^{-n})$. The leading coefficient $t^n$
then ensures that the $X$-norm will be controlled by a uniform constant for all $|t| \leq 1$. Finally,
multiplication by the fixed smooth cutoff $\phi(|x_0 - x_1| + |x_1 - y_0|)$ only increases the
norm by another finite constant.

Now it is a simple matter to show that $V_t$ produces a counterexample to (5.2)
and hence to (5.1) for $0 < t \ll 1$.

**Proposition 5.4.** Suppose $n > 3$. There exist constants $T, C_1, C_2 > 0$ such that if
$0 < t \leq T$ and $0 < \varepsilon < C_1 t$, then

$$\lim_{L \to \infty} \left| a^L_1(t, \varepsilon, V_t) \right| \geq C_2 t^{-\left(\frac{2n-1}{2} - 2\varepsilon \right)}.$$

*Proof.* Start with the asymptotic integral formula in (5.4). For any choice of points
$x \in \text{supp}(f^\varepsilon)$, $y \in \text{supp}(g^\varepsilon)$, $x_1 \in \text{supp}(V_t)$, the expression
$(|x-x_1| + |x_1-y|)^{n-2} (|x-x_1| + |x_1-y|)^{n-1/2}$ is a
smooth positive function of size comparable to 1.

Consider what happens to the integral over $dx_1$ in the special case when $x = x_0,
y = y_0$. Then, the oscillatory part of $V_t(x_1)$ is synchronized with the real part of
$e^{-i(|x-x_1| + |x_1-y|)^2/4t}$ so that the real part of the product is always positive and of
size approximately 1 on a set of approximately unit measure. The real part of
the integral is then bounded below by a positive constant.

For arbitrary $x \in \text{supp}(f^\varepsilon)$ and $y \in \text{supp}(g^\varepsilon)$, it is possible to differentiate under
the integral sign in either of the variables $x$ or $y$ and each partial derivative is
controlled by $t^{-1}$. Thus the lower bound on the real part of the integral remains
valid so long as $|x - x_0|, |y - y_0| \lesssim t$, which is ensured by setting $\varepsilon < C_1 t$.

The definition of $V_t$ also includes a factor of $t^n$. When this is substituted into
(5.4), the resulting leading coefficient is proportional to $t^{-\left(\frac{2n-1}{2} - 2\varepsilon \right)}$. There is also
an error term of unknown sign, but with size controlled by $t^{-\left(\frac{2n-1}{2} - 2\varepsilon \right)}$. This can be absorbed into the lower bound for any $0 < t \leq T$, provided $T$ is chosen sufficiently
small.

5.2. Nondispersive Estimate for the Full Evolution.

**Theorem 5.5.** Suppose $n > 3$. There cannot exist a bound of the form

$$\|e^{itH} P_{ac} f \|_\infty \leq C(V) |t|^{-\frac{n}{2}} \|f\|_1$$

with $C(V) < \infty$ for every potential $V \in X$, $\|V\|_X \leq 1$. 

Proof. Assume the contrary and write \( V = \theta W \) with \( \|W\|_X \leq 1 \) and \( \theta \in [0, 1] \). By assumption, we would then have the bound
\[
|\langle e^{itH_P}f, g \rangle| = \frac{1}{2\pi} \sup_{L \geq 1} \left| \int_0^\infty e^{it\lambda} \psi_L(\lambda) (|R_{\theta W}(\lambda + i0) - R_{\theta W}(\lambda - i0)|) f, g \, d\lambda \right|
\]
(5.6)
for \( \psi \) as in Lemma 5.1 and for every \( f, g \in L^1 \cap L^2 \) and, in particular, for the functions \( f^\epsilon, g^\epsilon \) defined in subsection 5.1.

The finite Born series expansion (2.5) allows us to write the perturbed resolvent \( R_{\theta W}(\lambda \pm i0) \) as the sum of a polynomial of degree \( 2m + 1 \) in \( \theta \) and a tail. When this is substituted into (5.6) above, along with the functions \( f^\epsilon, g^\epsilon \), the tail is shown in Theorem 4.1 to be controlled by \( C|t|^{-\frac{3}{2}} \|f\|_1 \|g\|_1 \) for some \( C \).

This, however, is precisely the same statement as (5.1) which was already shown to be false.

\[ \square \]

6. Proof of Lemma 5.1

The main ingredients of Lemma 5.1 are a recurrence relation (in \( n \)) for the resolvent kernels and explicit computations in dimensions 2 and 3. With some
abuse of notation, define $R_n^\pm(\lambda)$ to be the free resolvent $\lim_{\varepsilon \downarrow 0} (-\Delta - \lambda \pm i\varepsilon)^{-1}$ in $\mathbb{R}^n$. The Stone formula dictates that

$$\frac{1}{2\pi i} \int_0^\infty e^{it\lambda} \langle [R_n^+(\lambda) - R_n^-(\lambda)] f, g \rangle \, d\lambda = \langle e^{-it\Delta} f, g \rangle = (-4\pi i t)^{-\frac{n}{2}} \int_{\mathbb{R}^{2n}} e^{-\frac{(x - y)^2}{4t}} f(x)\overline{g(y)} \, dx \, dy$$

for all $t \neq 0$ and $f, g$ (say) Schwartz functions.

Recall that the resolvents $R_n(z) = (-\Delta - z)^{-1}$ can be defined for all $z \in \mathbb{C} \setminus \mathbb{R}^+$, and that $R_n^\pm(\lambda)$ are the analytic continuations onto the boundary from above and below, respectively. It follows that both $R_n^+(\lambda)$ and $R_n^-(\lambda)$ can be defined for negative values of $\lambda$. Moreover, $[R_n^+(\lambda) - R_n^-(\lambda)] = 0$ for all $\lambda \leq 0$. The integral above may therefore be taken over the entire real line.

One further observation is that since $R_n^+(\lambda)$ is a holomorphic family of operators for $\lambda$ in the upper halfplane and is uniformly bounded (as operators on $L^2$, for example) away from the real axis, its inverse Fourier transform must be supported on the halfline $\{t \leq 0\}$. Similarly, $R_n^-(\lambda)$, which is holomorphic in the lower halfplane, has inverse Fourier transform supported in $\{t \geq 0\}$. This leads to the conclusion

$$(6.1) \quad \int e^{it\lambda} R_n^- (\lambda, |x|) \, d\lambda = \begin{cases} -2\pi i (-4\pi i t)^{-\frac{n}{2}} e^{-\frac{|x|^2}{4t}}, & \text{if } t > 0 \\ 0, & \text{if } t < 0 \end{cases}$$

for all $x \in \mathbb{R}^n$. Setting $|x| = r$ in the preceding identity leads to the recurrence relation

$$(6.2) \quad R_{n+2}^-(\lambda, r) = -\frac{1}{2\pi r} \frac{\partial}{\partial r} [R_n^- (\lambda, r)].$$

The same identity also holds for $R_n^+(\lambda, r)$.

### 6.1. The cases $n = 2, 3$. It should first be noted that the integral $\int_\mathbb{R} e^{it\lambda} R_n^- (\lambda, r) \, d\lambda$ in (6.1) is never absolutely convergent and is properly interpreted as the Fourier transform of a distribution. As such, its behavior at $t = 0$ requires additional clarification.

**Lemma 6.1.** For any fixed $r > 0$ and $n = 2, 3$, the expression $\int_\mathbb{R} e^{it\lambda} R_n^- (\lambda, r) \, d\lambda$ agrees with the distribution $f$ given by

$$(6.3) \quad (f, \phi) = -2\pi i (-4\pi i)^{-\frac{n}{2}} \lim_{a \downarrow 0} \int_a^\infty t^{-\frac{n}{2}} e^{-\frac{|x|^2}{4t}} \phi(t) \, dt$$

for all Schwartz functions $\phi$.

**Proof.** Because of analyticity considerations, the identity above must be correct modulo distributions supported on $t = 0$. Let $\phi \in \mathcal{C}^\infty_c(\mathbb{R})$ have nonvanishing derivatives at $t = 0$ and consider pairings of the form $(f, N\phi(N\cdot))$.

On one hand, the function $t^{-n/2} e^{-ir^2/(4t)} \chi(0, \infty)$ has a continuous anti-derivative $I(t)$ with asymptotic behavior $I(t) = O(t^{2 - \frac{n}{2}})$ as $t$ approaches zero. Integrating by
For fixed $r > 0$, the resolvent $R_n(\lambda, r)$ possesses the asymptotic expansion
\[ R_n(\lambda, r) = c_1 r^{\frac{1}{2}} \lambda^{\frac{n+3}{4}} e^{-ir\sqrt{\lambda}} + O(\lambda^{-\frac{n+5}{4}}) \]
as $\lambda \to \infty$ and is integrable near $\lambda = 0$. Thus, it has a continuous anti-derivative $J(\lambda, r)$ which grows no faster than $O(\lambda^{\frac{n+1}{4}})$. Integrating by parts,
\[ \langle f, N\phi(N\cdot) \rangle = -N^{-1} \int_{\mathbb{R}} J(\lambda, r) \hat{\phi}(\lambda/N) \, d\lambda \]
\[ = O(N^{-\frac{n+1}{4}}). \]

As $n = 2, 3$, the difference between the left and right sides of (6.3) grows no faster than $O(N^{\frac{n}{2}})$ when applied to the test functions $N\phi(Nt)$. It is well-known that any nonzero distribution $g$ supported on $t = 0$ has the form $g = \sum_{k=1}^{M} c_k \phi^{(k)}(0)$, and would therefore grow at least as fast as $O(N)$ when applied to the same family of test functions. \[\Box\]

Having established the inverse Fourier transform of $R_n(\lambda, r)$ for each $r > 0$, it is possible to calculate the inverse Fourier transform of any product $R_n(\lambda, r)R_n(\lambda, s)$ by taking convolutions. Given a choice of $r, s, t > 0$,
\[ \int_{\mathbb{R}} e^{it\lambda} R_n(\lambda, r)R_n(\lambda, s) \, d\lambda = \frac{-2\pi}{(-4\pi i)^{\frac{n}{2}}} \int_{0}^{t} e^{-i\left(\frac{r^2}{4} + \frac{s^2}{4} - tu + r^2 t^2 - u^2 - r^2 t^2\right)} \frac{du}{u^{\frac{n}{2}}(t-u)^{\frac{n}{2}}} \]
where the Fourier transform has introduced a normalizing factor of $(2\pi)^{-1}$. To make the complex exponential more manageable, change variables to
\[ \frac{v}{t} = \frac{r^2}{u} + \frac{s^2}{t-u} - \frac{r^2 + s^2}{t} = \frac{(t-u)^2r^2 + u^2s^2}{u(t-u)t}. \]
The range of possible values for $v$ is $[2rs, \infty)$. Based on the quadratic relationship
\[ (r^2 + s^2 + v)u^2 - (2r^2 + v)tu + r^2t^2 = 0, \]
the variable substitutions for $u$ and $(t-u)$ are given by
\[ u = \left(\frac{2r^2}{2r^2 + v + \sqrt{v^2 - 4r^2s^2}}\right)t, \quad t-u = \left(\frac{1}{2r^2 + v + \sqrt{v^2 - 4r^2s^2}}\right)t. \]
The substitution formula for the differentials is
\[ du = \pm t \left(\frac{r(\sqrt{v+2rs} + \sqrt{v-2rs})}{2r^2 + v + \sqrt{v^2 - 4r^2s^2}}\right)^2 \frac{dv}{\sqrt{v^2 - 4r^2s^2}}. \]
Making all appropriate substitutions and correctly accounting for the fact that each value of \( v > 2rs \) is attained twice in \( u \in (0, t) \), the integral in (6.5) becomes

\[
\int_{\mathbb{R}} e^{it\lambda} R_{2}^{-} (\lambda, r) R_{2}^{-} (\lambda, s) \, d\lambda = \frac{1}{4\pi i} \int_{2rs}^{\infty} \frac{e^{-i\frac{\pi}{4}}}{\sqrt{v^2 - 4r^2s^2}} \, dv = \frac{1}{4\pi i} e^{-i\frac{\pi}{4}} H_{0}^{(1)} \left( -\frac{rs}{2i} \right)
\]

(6.5)

in the case \( n = 2 \). Here, \( H_{0}^{(1)} \) is the Hankel function introduced in Section 2. Some relevant properties of this function are that \( H_{0}^{(1)} (z) \) is analytic in the upper halfplane and decays asymptotically like \( \sqrt{\pi/2}ze^{iz} \) as \( z \to \infty \) along any ray.

In the case \( n = 3 \), the integral in (6.5) becomes

\[
\int_{\mathbb{R}} e^{it\lambda} R_{3}^{-} (\lambda, r) R_{3}^{-} (\lambda, s) \, d\lambda = -\frac{2\pi}{(-4\pi i)^{3/2}} \int_{2rs}^{\infty} \left[ \left( \frac{2r^2 + v^2 - 4rs}{r(\sqrt{v^2 - 4rs})} \right) + \left( \frac{2r^2 + v^2 - 4rs}{r(\sqrt{v^2 + 4rs})} \right) \right] \times \frac{e^{-i\frac{\pi}{4}}}{\sqrt{v^2 - 4r^2s^2}} \, dv
\]

\[
= -\frac{2\pi}{(-4\pi i)^{3/2}} \frac{r + s}{rs} \int_{2rs}^{\infty} \frac{e^{-i\frac{\pi}{4}}}{\sqrt{v - 2rs}} \, dv.
\]

At this point it remains to calculate the Fourier transform of an inverse square-root function, which yields

\[
\int_{2rs}^{\infty} \frac{e^{-i\frac{\pi}{4}}}{\sqrt{v - 2rs}} \, dv = e^{-i\frac{\pi}{4}} \sqrt{4\pi it}.
\]

The final result is

(6.6)

\[
\int_{\mathbb{R}} e^{it\lambda} R_{3}^{-} (\lambda, r) R_{3}^{-} (\lambda, s) \, d\lambda = \frac{1}{2i(-4\pi it)^{3/2}} \left( \frac{r + s}{rs} \right) e^{-i\frac{\pi}{4}} e^{i\frac{\pi}{4}}.
\]

6.2. Dimensions \( n > 3 \). The recurrence relation for \( R_{n+2}^{-} (\lambda) \) makes it possible to compute the analogous terms in dimensions \( n = 5, 7, \ldots \), by repeatedly applying the differential operator \( (4\pi^2rs)^{-1} \partial^2_{r^2} \) to the three-dimensional result (6.6). For small values of \( t \), the leading-order term occurs when all derivatives fall on \( e^{-i(r+s)^2/(4t)} \). This leads to the following asymptotic expression as \( t \to 0 \), which is valid in any odd dimension \( n \geq 3 \).

(6.7)

\[
\int_{\mathbb{R}} e^{it\lambda} R_{n}^{-} (\lambda, r) R_{n}^{-} (\lambda, s) \, d\lambda = \frac{1}{2it(-4\pi it)^{n/2}} \left[ (r + s)^{n-2} \right] \frac{e^{-i(r+s)^2/4t}}{rs^{n-1}} + O(t^{-(n-\frac{3}{2})}).
\]

The same result is true in even dimensions as well. To see this, recall that \( H_{0}^{(1)} (z) = \left( \frac{\pi}{2z} \right)^{1/2} e^{iz} \omega(z) \), where the derivatives of \( \omega \) satisfy the following bounds as \( |z| \) goes to infinity:

\[
\lim_{z \to \infty} \omega(z) = 1, \quad \left( \frac{\pi}{2z} \right)^{k} \omega(z) = O(|z|^{-k}), \quad k = 1, 2, \ldots
\]

The expression in (6.5) can then be rewritten as

\[
\int_{\mathbb{R}} e^{it\lambda} R_{2}^{-} (\lambda, r) R_{2}^{-} (\lambda, s) \, d\lambda = \frac{1}{2it(-4\pi it rs)^{1/2}} e^{-i(r+s)^2/4t} \omega \left( -\frac{rs}{2it} \right).
\]
Applying the differential operators $\frac{\partial}{\partial r}$ and $\frac{\partial}{\partial s}$ only increases the degree of the singularity at $t = 0$ when the derivative falls on the term $e^{-i(r+s)^2/(4t)}$. If the derivative falls instead on $\omega(-\frac{z^2}{2t})$, one power of $t$ is added to the denominator, but the effect is cancelled by the faster decay of $\frac{\partial}{\partial r} \omega(z)$. Consequently, when $(4\pi^2rs)^{-1} \frac{\partial^2}{\partial r \partial s}$ is applied iteratively to (5.5), the leading-order term results from having all of the derivatives fall on $e^{-i(r+s)^2/(4t)}$. The recurrence relation for $R_{n+2}(\lambda)$ then dictates that

$$
\int_{\mathbb{R}} e^{it\lambda} R_n^-(\lambda, A) R_n^-(\lambda, B) \, d\lambda = \frac{1}{2i(-4\pi i t)^{n-\frac{1}{2}}} \left[ \frac{(r+s)^{n-2}}{(rs)^{\frac{n}{2}}} \right] e^{-i(r+s)^2/4t} + O(t^{-(n-\frac{3}{2})})
$$

for dimensions $n = 4, 6, \ldots$, as desired. The results of this calculation can be summarized as follows.

**Proposition 6.2.** Suppose $n \geq 3$ and let $K$ be a compact subset of $(0, \infty)$. There exist constants $C_1, C_2 < \infty$, depending on $n$ and $K$, such that the remainder function

$$
G(r, s, t) := \int_{\mathbb{R}} e^{it\lambda} R_n^-(\lambda, A) R_n^-(\lambda, B) \, d\lambda - \frac{1}{2i(-4\pi i t)^{n-\frac{1}{2}}} \left( \frac{(r+s)^{n-2}}{(rs)^{\frac{n}{2}}} \right) e^{-i(r+s)^2/4t}
$$

satisfies the estimates

$$
|G(r, s, t)| \leq C_1 t^{-(n-\frac{3}{2})}, \quad \left| \frac{\partial}{\partial t} G(r, s, t) \right| \leq C_2 t^{-(n-\frac{3}{2})},
$$

uniformly in $r, s \in K$ and $0 < t \leq 1$.

**Proof.** One obtains an exact expression for $G(r, s, t)$ by differentiating the base case $n = 2$ or $n = 3$. Under the assumption $r, s \in K$, every monomial in $r$ and $s$ (including those with fractional and/or negative exponents) can be dominated by a constant. Every expression of the form $t^{-k} \frac{d^k}{dx^k} \omega(z)$ can also be bounded by a constant. Finally, nonnegative powers of $t$ are smaller than 1.

The function $G(r, s, t)$ consists of all the lower-order terms where at least one of the partial derivatives $\frac{\partial}{\partial r}$, $\frac{\partial}{\partial s}$ does not fall on the exponential $e^{-i(r+s)^2/(4t)}$. It follows that each of these terms is $O(t^{-(n-\frac{3}{2})})$. If the derivative $\frac{\partial}{\partial t}$ is taken at the end, this can only increase the sharpness of the singularity by a factor of $t^{-2}$. \qed

To be precise, the proposition above is describing the Fourier transform of a distribution as the integrand $R_n^-(\lambda, r) R_n^-(\lambda, s)$ experiences growth on the order of $|\lambda|^{\frac{n}{2}}$. In Lemma 5.1, the auxiliary function $\psi_L(\lambda)$ is introduced to make the integral absolutely convergent. This has the effect of convolving the distribution $G(r, s, \cdot)$ with the approximate identity $(2\pi)^{-1} \hat{\psi}_L$.

At a fixed time $0 < t \leq 1$, if $L \geq 2t^{-1}$ one can estimate the effect of the convolutions

$$
\left| \left[ (2\pi)^{-1} \hat{\psi}_L * (\cdot)^{-(n-\frac{3}{2})} e^{-i\frac{2+x^2}{4t}} \right] (t) - t^{-(n-\frac{3}{2})} e^{-i\frac{2+x^2}{4t}} \right| \leq C_{n, K} L^{-1} t^{-(n+\frac{3}{2})}
$$

and

$$
\left| \left[ (2\pi)^{-1} \hat{\psi}_L * G(r, s, \cdot) \right] (t) - G(r, s, t) \right| \leq C_{n, K} L^{-1} t^{-(n-\frac{3}{2})}
$$

by using the Mean Value Theorem and the support property of $\hat{\psi}$. If $L > Ct^{-3}$, these resulting differences are no larger than the initial size estimate for $G(r, s, t)$. 

Furthermore, at fixed $0 < t \leq 1$ they vanish in the limit $L \to \infty$ uniformly over all pairs $r, s \in K$.

Recall the definition of $I_L(t, |x - x_1|, |x_1 - y|)$ in the notation of this section:

$$I_L(t, |x - x_1|, |x_1 - y|) = \int e^{it\lambda} \left[ R_+^+(\lambda, |x - x_1|)R_+^-(\lambda, |x_1 - y|) - R_-^-(\lambda, |x - x_1|)R_-^+(\lambda, |x_1 - y|) \right] d\lambda.$$ 

Under the substitutions $r = |x - x_1|$ and $s = |x_1 - y|$, we have fully characterized the contribution of the term $e^{it\lambda} R_-^-(\lambda, r)R_-^+ (\lambda, s)$ to the integral. The inverse Fourier transform of $R_+^+(\lambda, r)R_+^-(\lambda, s)$ is a distribution supported on the half line $\{ t \leq 0 \}$ because of analyticity considerations. After convolution with $\hat{\psi}_L$, it will be supported in $(-\infty, L^{-1}]$ and therefore vanishes at any $t > 0$ once $L > t^{-1}$.

This concludes the proof of Lemma 5.1.
