ABSTRACT

Objective: The present study was designed to investigate the influencing factor of cardio-ankle vascular index (CAVI) in natural population of She minority in China.

Methods: Five hundred and twenty-four subjects were enrolled into our study (male 227 and female 297). Main analyzing indexes included vascular related markers namely of CAVI and carotid artery intima-media thickness (CIMT) and blood markers.

Results: Systolic blood pressure (SBP) and diastolic blood pressure (DBP) were high in the entire population (150.08±23.32 mmHg, 91.15±12.42 mmHg). CAVI, left CIMT and right CIMT were normal. Univariate analysis showed CAVI was positively correlated with age, waist hip ratio (WHR), SBP, DBP, pulse pressure (PP), blood urea nitrogen (BUN), serum creatinine (Cr), fasting plasma glucose (FPG), triglyceride (TG), total cholesterol (TC), low density lipoprotein cholesterol (LDL-C), high sensitive C reactive protein (hs-CRP), left CIMT and right CIMT (r=0.570, 0.240, 0.512, 0.372, 0.459, 0.231, 0.095, 0.182, 0.158, 0.164, 0.167, 0.169, 0.395, 0.407, all p<0.05). Multivariate linear regression analysis (selected factors including age, heart rate (HR), body mass index (BMI), WHR, SBP, DBP, PP, blood uric acid (UA), BUN, Cr, FPG, TC, TG, high density lipoprotein cholesterol (HDL-C), LDL-C, hs-CRP, left CIMT and right CIMT) showed that age, SBP, FPG, hs-CRP, TG and Cr were the independent related factors of CAVI (adjusted R²=0.399).

Conclusion: Age, systolic blood pressure, fasting plasma glucose, high sensitive C-reactive protein, triglyceride and creatinine levels were independent factors of CAVI in natural populations of She minority in China.

KEYWORDS: She minority; Arterial stiffness; Cardio-ankle vascular index (CAVI).

INTRODUCTION

Arterial stiffness has been considered as a surrogating indicator of atherosclerosis progression and degree of vascular injury. In addition, arterial stiffness is an independent risk factor and predictor of cardiovascular disease. There were many evaluation methods of arterial stiffness, cardio-ankle vascular index (CAVI) was a new marker reflecting the whole arterial stiffness from aortic to ankle and independently of immediate blood pressure during measurement. Therefore, CAVI was used as a reliable evaluation of early vascular injury. It has been considered as a quantitative assessment of disease progression and therapeutic efficacy. Recent
years, many studies about CAVI found that it was closely related to vascular injuries in patients with hypertension, diabetes mellitus and dyslipidemia, and was regarded as a useful tool for screening of vascular health in patients with metabolic syndrome.\textsuperscript{2,3} Furthermore, the new vascular health classification also included CAVI as an evaluation index of vascular health.\textsuperscript{2} However, few study assessed CAVI in a minority population of China. People of the minority lived in a natural mountain area without known vascular related diseases and with little interference from modern society. Therefore, the present study was to evaluate the vascular status using CAVI and assess its influencing factors.

### SUBJECTS

A total of 524 subjects from 6 natural minority villages using a cluster sampling method were enrolled into the present study, including male 227 and female 297 with 14-85 years old. Subjects with ankle brachial index equal or below 0.9, serious liver and kidney dysfunction, systematic inflammatory disease, infectious disease and cancer were excluded the study.

The ethics committee of Mindong Hospital in China approved the study. And all participants completed informed consent.

### METHODS

#### The Detection of CAVI

According to the guideline of early vascular detection system (the second report),\textsuperscript{1} CAVI was detected by the vascular measurement apparatus VS-1000 (Fukuda Denshi Co. Ltd, Japan) automatically. Subjects were asked to rest for 10 minutes with a supine position. Electrodes were placed on the wrists to collect the ECG waveform, and micro heart sound recorder was placed in the fourth intercostal space of left sternal to capture the heart sounds, and a blood pressure cuff was attached to the double arm in the fourth intercostal space of left sternal to capture the heart sounds, and a blood pressure cuff was attached to the double arm with appropriate tightness, and then the value of CAVI as an evaluation index of vascular health.\textsuperscript{12} However, in the present study, we found the mean level of both SBP and DBP were high, but the mean CAVI and CIMT were in a normal level. People were asked to complete a questionnaire for the collection of age, gender, history of diseases (such as hypertension, diabetes mellitus, coronary artery disease, cerebral infarction and peripheral artery disease) and life habits.

#### The Measurement of CIMT

According to the proposal of series studies on arterial stiffness (the second report),\textsuperscript{1} CIMT was measured at the lateral carotid sinus 1.5 cm as the CIMT examination site and found that CAVI was both increased by age. However, CAVI and CIMT were both in the mean normal level. People were asked to complete a questionnaire for the collection of age, gender, history of diseases (such as hypertension, diabetes mellitus, coronary artery disease, cerebral infarction and peripheral artery disease) and life habits.

#### Laboratory Examination

All subjects were drawn the fasting venous blood and using EDTA anticoagulant, and TC, TG, LDL-C, HDL-C, FPG, UA, BUN, Cr and hs-CRP were measured by automatic analyzer.
Table 1: General clinical characteristics of all subjects.

| Variables (N=524) | Mean±standard deviation (x̅±s) |
|-------------------|-------------------------------|
| Age (year)        | 47.95±13.48                  |
| Male/Female       | 227/297                      |
| BUN (mmol/L)      | 5.09±1.73                    |
| Cr (μmol/L)       | 65.02±18.54                  |
| UA (μmol/L)       | 284.48±83.34                 |
| FPG (mmol/L)      | 5.42±1.35                    |
| TC (mmol/L)       | 5.15±1.37                    |
| TG (mmol/L)       | 1.25±1.04                    |
| HDL-C (mmol/L)    | 1.59±0.49                    |
| LDL-C (mmol/L)    | 2.93±0.89                    |
| hsCRP (mg/L)      | 3.87±6.46                    |
| BMI (kg/m²)       | 24.1±3.33                    |
| HR (beats/minutes)| 71.4±13.23                   |
| WHR               | 0.90±0.05                    |
| CAVI              | 7.32±1.30                    |
| SBP (mmHg)        | 150.08±23.32                 |
| DBP (mmHg)        | 91.15±12.42                  |
| PP (mmHg)         | 58.93±15.99                  |
| Left CIMT (μm)    | 557.55±134.15                |
| Right CIMT (μm)   | 541.01±132.86                |

Table 2: Pearson correlation between CAVI and other variables.

| Variables (N=524) | r     | p     |
|-------------------|-------|-------|
| Age (year)        | 0.570 | <0.05 |
| BMI (kg/m²)       | -0.060| 0.183 |
| WHR               | 0.240 | <0.05 |
| HR (beats/minutes)| 0.034 | 0.447 |
| SBP (mmHg)        | 0.512 | <0.05 |
| DBP (mmHg)        | 0.372 | <0.05 |
| PP (mmHg)         | 0.459 | <0.05 |
| BUN (mmol/L)      | 0.231 | <0.05 |
| Cr (μmol/L)       | 0.095 | <0.05 |
| UA (μmol/L)       | 0.086 | 0.079 |
| FPG (mmol/L)      | 0.182 | <0.05 |
| TG (mmol/L)       | 0.158 | <0.05 |
| TC (mmol/L)       | 0.164 | <0.05 |
| LDL-C (mmol/L)    | 0.167 | <0.05 |
| HDL-C (mmol/L)    | 0.025 | 0.610 |
| hs-CRP (mg/L)     | 0.169 | <0.05 |
| Left CIMT (μm)    | 0.395 | <0.05 |
| Right CIMT (μm)   | 0.407 | <0.05 |

Table 3: Multiple linear regression analysis between CAVI and other variables (adjusted R²=0.399).

| Final entered variables (Adjusted R²=0.399) | Adjusted β | p     |
|--------------------------------------------|------------|-------|
| Age (year)                                 | 0.346      | <0.05 |
| SBP (mmHg)                                 | 0.202      | <0.05 |
| FPG (mmol/L)                               | 0.179      | <0.05 |
| hs-CRP (mg/L)                              | 0.157      | <0.05 |
| TG (mmol/L)                                | 0.146      | <0.05 |
| Cr (μmol/L)                                | 0.138      | <0.05 |
Age, SBP, FPG, Cr were independent influencing factors of CAVI in Chinese; age, SBP, HDL-C, Cr, BMI, FPG were independent influencing factors of Japanese population. CAVI were both correlated with age, SBP, BMI in healthy women of Chinese and Japanese. In addition, CAVI were independently related to age, BMI, HbA1c, HDL-C in patients with hypertension and diabetes mellitus and community residents. In addition, CAVI level was different between the northern and southern area which was higher in the south region in China. Other studies also indicated CAVI were independently related to Cr and homocysteine. Study on another minority in China namely Miao minority showed that age, SBP, uric acid, BMI were independent influencing factors of CAVI. Therefore, the above studies informed us that the influencing factors of CAVI were different in different populations. Thus, the present study added some more information on CAVI in a She minority population in China. The results will provide special intervention for different populations and it was also the embodiment of precision medicine.

MERITS AND LIMITATIONS

The subjects enrolled into the study were from natural mountain areas of China. In these areas, people lived with farming works and far away from the cities. People there were influenced little by the modern society and lived with less mental stress. They also ate natural homemade foods. In addition, the participants were almost farmers, thus they knew little about their health or disease condition, therefore few of them were taking drugs which would have little influence on CAVI. Therefore, the results can reflect the natural relationship between CAVI and other markers. In addition, few studies in the China have assessed the influencing factors of She minority. The present study provided a reference for the related factors of CAVI in She minority and some clues for the following-up studies.

However, the above merits may also be the limitations of the study. We could not evaluate the difference between different diseases status in CAVI because of the limited medical knowledge of the local people. Finally, the study was observational and can only provide limited information about CAVI. We have conducted follow-up study for this population and further research results will add more information on CAVI and its influencing factors.

CONCLUSION

The mean level of blood pressure was high but the mean CAVI and CIMT were at the normal level in the natural population of She minority in China. Furthermore, age, systolic blood pressure, fasting plasma glucose, high sensitive C-reactive protein, triglyceride and creatinine levels were independent factors of CAVI in the minority in China. Therefore, in the She minority population, we should focus more on the above influencing factors on CAVI and carry out some early intervention strategies for prevention.
