1INTRODUCTION

The International League Against Epilepsy (ILAE) / American Epilepsy Society (AES) Task Force on the cardiac effects of lamotrigine was convened in response to a recent addition to the lamotrigine label by the US Food and Drug Administration (FDA). Lamotrigine is the nonproprietary name for a medicine that is sold under its generic name and several brand names including Lamictal™. The present advisory is based on an assessment of currently available evidence. It is not intended to replace regulatory requirements, nor is it intended to be an exhaustive review. Its purpose is to advise healthcare professionals worldwide on how to minimize cardiac safety risks associated with lamotrigine use.

2WHAT WAS ADDED TO THE US LABEL?

The following two paragraphs were added:

Warnings and precautions (5.4). Cardiac Rhythm and Conduction Abnormalities: In vitro testing showed that Lamictal exhibits class IB antiarrhythmic activity at therapeutically relevant concentrations [see Clinical Pharmacology (12.2)]. Based on this activity, Lamictal...
could slow ventricular conduction (widen QRS) and induce proarrhythmia, including sudden death, in patients with structural heart disease or myocardial ischemia. Therefore avoid the use of Lamictal in patients who have cardiac conduction disorders (eg, second- or third-degree heart block), ventricular arrhythmias, or cardiac disease or abnormality (eg, myocardial ischemia, heart failure, structural heart disease, Brugada syndrome, or other sodium channelopathies). Concomitant use of other sodium channel blockers may increase the risk of proarrhythmia.

Clinical Pharmacology (12.2). Effect of Lamictal: In vitro studies show that lamotrigine exhibits class IB antiarrhythmic activity at therapeutically relevant concentrations. It inhibits human cardiac sodium channels with rapid onset and offset kinetics and strong voltage dependence, consistent with other class IB antiarrhythmic agents. Lamictal did not slow ventricular conduction (widen QRS) in healthy individuals in a thorough QT study; however, it could slow ventricular conduction and increase the risk of arrhythmia in patients with structural heart disease or myocardial ischemia. Elevated heart rates could also increase the risk of ventricular conduction slowing with Lamictal.

3 | HAVE REGULATORY AGENCIES OTHER THAN THE FDA ADDED ANY WARNING?

To date, the European Medicines Agency (EMA) has not added any warnings, and we know of no new warnings from other countries at this time.

4 | ARE THESE WARNINGS AND PRECAUTIONS ONLY RELEVANT TO LAMOTRIGINE OR ARE THEY ALSO APPLICABLE FOR OTHER SODIUM CHANNEL BLOCKERS?

The cardiac concerns stem from lamotrigine's sodium channel blocking properties. No differences in the occurrence of EKG abnormalities have been reported in two small studies that compared lamotrigine with carbamazepine, including specifically elderly individuals with epilepsy. However, we are not aware of any head-to-head comparative thorough clinical study of the effects of lamotrigine and other sodium channel blockers on cardiac electrophysiology. A synergistic pharmacodynamic interaction with other substances with sodium channel blocking properties may be expected and potentially increase the risk of adverse cardiac effects (see also item #10).

5 | THESE WARNINGS STEM FROM IN VITRO DATA. ARE THESE DATA AVAILABLE?

We are aware of a previous study by Harmer et al that raised concerns at the FDA. While that study has limitations that bring its clinical relevance into question, it is our understanding that it led to a request by the FDA for a subsequent in vitro study from Lamictal's manufacturer, GlaxoSmithKline (GSK). As per GSK, that work was completed in 2019 and showed that lamotrigine can weakly inhibit cardiac sodium channels, showing class IB antiarrhythmic activity. That in vitro information led to the recent US package insert update and warning. The task force has requested the in vitro data from GSK, but to date this has not been provided.

6 | HAVE HUMAN STUDIES BEEN PERFORMED TO EVALUATE THIS?

While in vitro data indicate lamotrigine has class IB antiarrhythmic sodium channel blocking properties, there is no change in ventricular conduction (QRS duration) in healthy individuals and individuals with epilepsy without heart disease. A modest increase in the AV conduction interval (PR prolongation) may occur, especially at high doses. Significantly, unlike class IA antiarrhythmic drugs, lamotrigine does not prolong repolarization (no change in QT) in healthy people at thorough QT testing. At high doses of lamotrigine, there is a mild QT shortening observed, which is a class IB property. Thus, based on the absence of QRS or QT changes, and only mild PR prolongation even at high doses, there is not an apparent arrhythmia risk of lamotrigine therapy in healthy people without heart disease. It should also be noted that the class IB antiarrhythmic drugs lidocaine and mexiletine have a long record of use in people with ischemic heart disease.

7 | ARE THERE ANY DATA THAT ARRHYTHMIAS OR SUDDEN DEATHS DUE TO CARDIAC ISSUES ARE MORE COMMON IN PEOPLE ON LAMOTRIGINE COMPARED WITH OTHER ANTISEIZURE MEDICATIONS (ASMs)?

To our knowledge, an increased risk of arrhythmias or sudden deaths due to cardiac issues or need for pacemaker therapy in people on lamotrigine as compared to other ASMs has not been demonstrated. Sudden unexpected death in epilepsy (SUDEP) is, however, relatively common in people with epilepsy. In adults with epilepsy, the overall rate of SUDEP is approximately 1:1000/year, but the risk is higher in people with
frequent convulsive seizures. Thus, an increase in sudden cardiac death caused by lamotrigine could theoretically be missed if it occurred at a very low frequency in relation to SUDEP risk.

8 | THE WARNING STATES THAT LAMOTRIGINE COULD POSE A RISK TO PEOPLE WITH UNDERLYING CARDIAC DISEASE AND NOT HEALTHY INDIVIDUALS. SHOULD I BE PERFORMING EKGs IN MY HEALTHY PATIENTS TO LOOK FOR UNDERLYING CARDIAC DISEASE?

The risk of undiagnosed asymptomatic cardiac disease under the age of 60 years is minimal in the absence of major cardiovascular risk factors such as diabetes, hypertension, familial hypercholesterolemia, and smoking. In people over the age of 60 years, the likelihood of undiagnosed cardiac conduction abnormalities increases, and an EKG may be considered prior to initiating lamotrigine. An EKG should also be considered in people younger than 60 with known cardiac disease or significant risk factors as above.

9 | IF I PERFORM AN EKG AND IT IS ABNORMAL, DOES THAT MEAN I SHOULD NOT INITIATE LAMOTRIGINE?

Nonspecific EKG abnormalities (eg, nonspecific ST and T wave abnormalities) are not concerning and should not preclude these individuals from being prescribed lamotrigine.

The highest risk cases are those with 2nd- and 3rd-degree heart block, Brugada syndrome, arrhythmogenic ventricular cardiomyopathy (ARVC), left bundle branch block (LBBB), and right bundle branch block (RBBB) with left anterior or posterior fascicular block. These patients require thorough cardiological investigation to determine whether lamotrigine can be administered safely. If there are concerns, consultation with a cardiologist before initiating lamotrigine may be warranted.

10 | OFTEN ASMS NEED TO BE INITIATED AS QUICKLY AS POSSIBLE AFTER A DIAGNOSIS OF EPILEPSY IS MADE. DO I HAVE TO WAIT TO START LAMOTRIGINE UNTIL I OBTAIN THE RESULTS OF THE EKG?

In most cases, the initial EKG can be obtained while titrating, mainly when the individual is at the first dose of 25 mg/day because lamotrigine must be titrated slowly, and because cardiac adverse events are dose-related.

11 | ONCE AN INDIVIDUAL IS ON LAMOTRIGINE DOES THE EKG NEED TO BE REPEATED?

If used in people at risk, a repeat EKG should be considered at the target dose, mainly when the target dose (or the serum lamotrigine level) is near or above the upper limit of the therapeutic range, and always in the presence of concomitant use of other sodium channel blockers or substances known to impair atrioventricular and/or intraventricular cardiac conduction. Because concomitant use of such drugs put people at increased risk of impaired cardiac conduction when adding lamotrigine, an initial EKG should also be performed.

12 | ARE THERE ANY OTHER CARDIOVASCULAR SITUATIONS THAT I SHOULD WORRY ABOUT, PARTICULARLY FOR PEOPLE WHO ARE ALREADY ON LAMOTRIGINE?

Clinicians should consider obtaining an EKG and/or cardiology consultation in people on lamotrigine with sudden onset syncope or presyncope with loss of muscular tone without a clear vasovagal or orthostatic cause.

ACKNOWLEDGMENTS
This document was written with the contribution of experts selected by the International League Against Epilepsy (ILAE) and was approved for publication by the ILAE. Opinions expressed by the authors, however, do not necessarily represent the policy or position of the ILAE. Appreciation is expressed to Aatif Husain, MD, Chair of the AES Guidelines and Assessment Committee, for the early alert of the potential significance of the FDA warning to providers and patients and to Barry Gidal, PharmD, Chair of the American Epilepsy Society (AES) Treatments Committee, for facilitating AES-ILAE collaboration on this advisory statement.

CONFLICT OF INTEREST
DGV’s institution receives payment for his work as principal investigator on antiseizure medication trials for SK Life Science and Xenon, Inc. EP received speaker’s or consultancy fees from Amicus Therapeutics, Arvelle, Biogen, Corlieve, Eisai, GW Pharma, Intas Pharmaceuticals, Laboratorios Bagó, Sanofi, Sun Pharma, UCB Pharma, and Xenon Pharma. JAF receives NYU salary support from the Epilepsy Foundation and for consulting work and/or attending Scientific Advisory Boards on behalf of the Epilepsy Study Consortium for Adamas,
Epilepsia Open
