ON NASH APPROXIMATION OF COMPLEX ANALYTIC SETS IN RUNGE DOMAINS

JANUSZ ADAMUS AND MARCIN BILSKI

Abstract. We prove that every complex analytic set $X$ in a Runge domain $\Omega$ can be approximated by Nash sets on any relatively compact subdomain $\Omega_0$ of $\Omega$. Moreover, for every Nash subset $Y$ of $\Omega$ with $Y \subset X$, the approximating sets can be chosen so that they contain $Y \cap \Omega_0$. As a consequence, we derive a necessary and sufficient condition for a complex analytic set $X$ to admit a Nash approximation which coincides with $X$ along its arbitrary given subset.

1. Introduction and main results

A basic problem in complex analysis is to approximate holomorphic maps by algebraic ones. Classical results here are the Runge approximation theorem and the Oka-Weil approximation theorem. These theorems have been generalized in many directions (see [11], [12], [13], [14], [18], [19], [20], [25], [27] and references therein).

The problem of algebraic approximation of holomorphic maps has a natural generalization in complex analytic geometry. Namely, one can ask whether a complex analytic set can be approximated by algebraic sets or by branches of algebraic sets (called Nash sets). In the case when the analytic set under consideration has only isolated singularities (or, even, is non-singular) the latter question is closely related to the classical problem of transforming an analytic set onto a Nash one by a biholomorphic map (see [3], [11], [19], [24], [26]).

The situation is quite different when the singular locus is of higher dimension. Then there exist germs of complex analytic sets which are not biholomorphically equivalent to any germ of a Nash set (see [31]). In general, only topological equivalence of analytic and Nash set germs holds true (cf. [21]). Nevertheless, by [5] and [11], every analytic subset $X$ of $D \times \mathbb{C}^p$ of pure dimension $n$ with proper projection onto $D$, where $D \subset \mathbb{C}^n$ is a Runge domain, can be approximated by (branches of) algebraic sets of pure dimension $n$. (This immediately implies that every analytic set admits a local algebraic approximation.)

The first goal of the present paper is to prove the following fundamental theorem, which strengthens the approximation results of [5] by showing that it is not necessary to require that $X$ have a proper projection onto some Runge domain in $\mathbb{C}^n$. Moreover, for every Nash subset $Y$ contained in $X$, the approximating sequence $(X_\nu)_{\nu \in \mathbb{N}}$ can be chosen so that $Y \subset X_\nu$ for all $\nu$. (See Section 2 for the definitions and basic properties of the notions used below.)

The research was partially supported by Natural Sciences and Engineering Research Council of Canada (J. Adamus) and NCN (M. Bilski).
Theorem 1.1. Let $\Omega$ be a Runge domain in $\mathbb{C}^q$, and let $X$ be a complex analytic subset of $\Omega$ of pure dimension $n$. Let $Y$ be a Nash subset of $\Omega$ such that $Y \subset X$. Then, for every open $\Omega_0$ relatively compact in $\Omega$, there exists a sequence $(X_\nu)_{\nu \in \mathbb{N}}$ of Nash subsets of $\Omega_0$ of pure dimension $n$ converging to $X \cap \Omega_0$ in the sense of holomorphic chains and such that $X_\nu \supset Y \cap \Omega_0$ for all $\nu$.

Given a complex analytic set $X$ in a Runge domain, denote by $\mathcal{NA}(X)$ the class of those sets $R \subset X$ for which $X$ admits a Nash approximation along $R$. Theorem 1.1 immediately implies that $R \in \mathcal{NA}(X)$ provided $R$ is contained in a Nash set $Y$ with $Y \subset X$. A natural question is whether the latter condition characterizes the class $\mathcal{NA}(X)$. In Section 4 we show that this is indeed the case. Moreover, using the results of [1], we show that the class $\mathcal{NA}(X)$ contains all the semialgebraic sets contained in $X$ (a family strictly larger than that of Nash sets contained in $X$).

Theorem 1.2. Let $\Omega$ be a Runge domain in $\mathbb{C}^q$. Let $X$ be a complex analytic subset of $\Omega$ of pure dimension $n$, and let $R$ be an arbitrary subset of $X$. The following conditions are equivalent:

(i) For every open $\Omega_0$ relatively compact in $\Omega$, there exists a sequence $(X_\nu)_{\nu \in \mathbb{N}}$ of Nash subsets of $\Omega_0$ of pure dimension $n$ converging to $X \cap \Omega_0$ in the sense of holomorphic chains and such that $X_\nu \supset R \cap \Omega_0$ for all $\nu$.

(ii) For every open $\Omega_0$ relatively compact in $\Omega$, there exists a sequence $(X_\nu)_{\nu \in \mathbb{N}}$ of Nash subsets of $\Omega_0$ of pure dimension $n$ converging to $X \cap \Omega_0$ locally uniformly and such that $X_\nu \supset R \cap \Omega_0$ for all $\nu$.

(iii) For every open $\Omega_0$ relatively compact in $\Omega$, there exists a semialgebraic set $S$ such that $R \cap \Omega_0 \subset S \subset X$.

(iv) For every point $a$ in the Euclidean closure of $R$ in $\Omega$, there is a semialgebraic germ $S_a$ such that $R_a \subset S_a \subset X_a$.

(v) For every open $\Omega_0$ relatively compact in $\Omega$, there exists a Nash set $Y$ in $\Omega_0$ such that $R \cap \Omega_0 \subset Y \subset X$.

(vi) For every point $a$ in the Euclidean closure of $R$ in $\Omega$, there is a Nash germ $Y_a$ such that $R_a \subset Y_a \subset X_a$.

The equivalence of conditions (ii) and (vi) above is related to the so-called holomorphic closure of $R$ at a point. Holomorphic closure of real analytic and semialgebraic sets has been studied in [1] and [2] and has been used to develop CR geometry in the singular setting. The above theorem can be regarded as a characterization of germs $R_a$ whose holomorphic closure is contained in a Nash subgerm of $X_a$. Namely, the latter holds precisely when $X$ can be approximated locally uniformly along $R$ by Nash sets in a neighbourhood of $a$.

In the following section, we recall basic definitions and facts used throughout the paper. Theorems 1.1 and 1.2 will be proved in Sections 3 and 4 respectively. Results on Nash approximation of analytic sets can be used, in particular, for approximation of holomorphic functions. We give an application of this kind in the last section.

2. Preliminaries

2.1. Analytic subsets of domains of holomorphy. The following proposition is well known (see, e.g., [10], p. 192).
Proposition 2.1. Let $\Omega \subset \mathbb{C}^q$ be a domain of holomorphy, let $A$ be an analytic subset of $\Omega$, and let $a \in \Omega \setminus A$. Then, there exists $f \in \mathcal{O}(\Omega)$ such that $A \subset f^{-1}(0)$ and $f(a) \neq 0$.

As an immediate consequence of Proposition 2.1 one obtains that analytic subsets of a domain of holomorphy can be described by global analytic functions.

Theorem 2.2. Let $\Omega \subset \mathbb{C}^q$ be a domain of holomorphy and let $A$ be an analytic subset of $\Omega$. Then, there are $f_1, \ldots, f_m \in \mathcal{O}(\Omega)$ such that $A = \{ z \in \Omega : f_1(z) = \ldots = f_m(z) = 0 \}$.

2.2. Runge domains and polynomial polyhedra. A domain of holomorphy $\Omega \subset \mathbb{C}^q$ is called a Runge domain if every function $f \in \mathcal{O}(\Omega)$ can be uniformly approximated on every compact subset of $\Omega$ by polynomials in $q$ complex variables.

We say that a set $P$ is a polynomial polyhedron in $\mathbb{C}^q$ if there exist polynomials $f_1, \ldots, f_s \in \mathbb{C}[Z_1, \ldots, Z_q]$ and real constants $c_1, \ldots, c_s$ such that

$$P = \{ z \in \mathbb{C}^q : |f_1(z)| \leq c_1, \ldots, |f_s(z)| \leq c_s \}.$$

Let us recall a straightforward consequence of Theorem 2.7.3 and Lemma 2.7.4 from [16].

Theorem 2.3. Let $\Omega \subset \mathbb{C}^q$ be a Runge domain. Then, for every open $\Omega_0 \subset \Omega$ there exists a compact polynomial polyhedron $P \subset \Omega$ such that $\Omega_0 \subset P$.

(Here and throughout, we use the shorthand notation $A \in B$ to indicate that $A$ is a relatively compact subset of $B$.)

2.3. A division theorem. The following result is a simplified version of a division theorem of [17].

Theorem 2.4 (cf. [17 Cor. 2.10.3]). Let $\Omega \subset \mathbb{C}^q$ be a domain of holomorphy. Let $F = (F_1, \ldots, F_N) : \Omega \to \mathbb{C}^N$ be a holomorphic mapping with $F \neq 0$ and let $\mu = \min\{q, N-1\}$. Then, for any $G \in \mathcal{O}(\Omega)$ with $\|G \cdot |F|^{-(2\mu+1)}\|_{L^2(\Omega)} < +\infty$ there exist $u_1, \ldots, u_N \in \mathcal{O}(\Omega)$ such that $G = u_1 F_1 + \ldots + u_N F_N$.

Corollary 2.5. Let $D$ be any domain in $\mathbb{C}^q$ and let $\Omega \Subset D$ be a domain of holomorphy. Let $F = (F_1, \ldots, F_N) : D \to \mathbb{C}^N$ be a holomorphic mapping with $F \neq 0$. Then, for any $G \in \mathcal{O}(D)$ with $\{ F_1 = \ldots = F_N = 0 \} \subset \{ G = 0 \}$, there are $m \in \mathbb{N}$ and $u_1, \ldots, u_N \in \mathcal{O}(\Omega)$ such that $G^m = u_1 F_1 + \ldots + u_N F_N$ on $\Omega$.

Proof. The facts that $\{ F_1 = \ldots = F_N = 0 \} \subset \{ G = 0 \}$ and $\Omega$ is relatively compact in $D$ immediately imply that, for $m \in \mathbb{N}$ large enough, $\|G^m \cdot |F|^{-(2\mu+1)}\|_{L^2(\Omega)} < +\infty$, where $\mu = \min\{q, N-1\}$. Hence the assertion follows from Theorem 2.4.

2.4. Nash sets. By a Nash set (resp. germ, function, etc.) we shall always mean a complex Nash set (resp. germ, function, etc.), in the following sense. Let $\Omega$ be an open subset of $\mathbb{C}^q$ and let $f$ be a holomorphic function on $\Omega$. We say that $f$ is a Nash function at $\zeta \in \Omega$ if there exist an open neighbourhood $U$ of $\zeta$ in $\Omega$ and a polynomial $P \in \mathbb{C}[Z_1, \ldots, Z_q, W]$, $P \neq 0$, such that $P(z, f(z)) = 0$ for $z \in U$.

A holomorphic function on $\Omega$ is a Nash function if it is a Nash function at every point of $\Omega$. A holomorphic mapping $\varphi : \Omega \to \mathbb{C}^N$ is a Nash mapping if each of its components is a Nash function on $\Omega$.

A subset $X$ of $\Omega$ is called a Nash subset of $\Omega$ if for every $\zeta \in \Omega$ there exist an open neighbourhood $U$ of $\zeta$ in $\Omega$ and Nash functions $f_1, \ldots, f_s$ on $U$, such that
X \cap U = \{z \in U : f_1(z) = \cdots = f_s(z) = 0\}. A germ \(X_\zeta\) of a set \(X\) at \(\zeta \in \Omega\) is a Nash germ if there exists an open neighbourhood \(U\) of \(\zeta\) in \(\Omega\) such that \(X \cap U\) is a Nash subset of \(U\). Equivalently, \(X_\zeta\) is a Nash germ if its defining ideal can be generated by convergent power series algebraic over the polynomial ring \(\mathbb{C}[Z_1, \ldots, Z_q]\). A detailed exposition of complex Nash sets and mappings can be found in [28]. Let us only recall here a useful characterisation of irreducible Nash sets:

**Theorem 2.6** (cf. [28] Thm. 2.10, Thm. 2.11). Let \(X\) be an irreducible Nash subset of an open set \(\Omega \subset \mathbb{C}^q\). Then, there exists an algebraic subset \(Z\) of \(\mathbb{C}^q\) such that \(X\) is an analytic irreducible component of \(Z \cap \Omega\). Conversely, every analytic irreducible component of \(Z \cap \Omega\) is an irreducible Nash subset of \(\Omega\).

(Since irreducible components of a Nash set are Nash, an irreducible Nash set is simply a Nash set which is irreducible as a complex analytic set.)

### 2.5. Semialgebraic sets.

Identifying \(\mathbb{C}^q\) with \(\mathbb{R}^{2q}\), one can speak of semialgebraic sets and functions in \(\mathbb{C}^q\). Quite generally, let \(M\) be a finite-dimensional \(\mathbb{R}\)-vector space. A choice of base for \(M\) gives a linear isomorphism \(\psi : \mathbb{R}^m \to M\), where \(m = \dim M\). We say that a function \(f : M \to \mathbb{R}\) is a polynomial function on \(M\) if there exists \(P \in \mathbb{R}[X_1, \ldots, X_m]\) such that \((f \circ \psi)(x) = P(x)\) for all \(x = (x_1, \ldots, x_m) \in \mathbb{R}^m\).

Since linear base change is a polynomial mapping (with polynomial inverse), it follows that the above definition is independent of the choice of base for \(M\). We say that a subset \(S\) of \(M\) is semialgebraic if \(S\) is a finite union of sets of the form

\[
\{x \in M : f_1(x) = \cdots = f_r(x) = 0, g_1(x) > 0, \ldots, g_s(x) > 0\},
\]

where \(r, s \in \mathbb{N}\) and \(f_1, \ldots, f_r, g_1, \ldots, g_s\) are polynomial functions on \(M\). One easily checks that the union and intersection of two semialgebraic sets are semialgebraic, as is the complement of a semialgebraic set.

Let \(\Omega\) and \(\Delta\) be open subsets of finite-dimensional \(\mathbb{R}\)-vector spaces \(M\) and \(N\) respectively. A mapping \(\varphi : \Omega \to \Delta\) is called a semialgebraic mapping if its graph is a semialgebraic subset of \(M \times N\). The Tarski-Seidenberg Theorem (see, e.g., [8] Prop. 2.2.7) ensures that the image (resp. the inverse image) by \(\varphi\) of a semialgebraic subset of \(M\) (resp. \(N\)) is semialgebraic in \(N\) (resp. \(M\)). Apart from the above facts, we will use the following properties of semialgebraic sets:

**Remark 2.7.**

1. [8] Prop. 2.2.2. If \(S\) is semialgebraic in \(M\), then the topological closure and interior of \(S\) in \(M\) are semialgebraic sets.

2. [8] Thm. 2.9.10. Every semialgebraic subset of \(M\) is a disjoint union of a finite family of sets, each of which is a connected real analytic manifold and a semialgebraic subset of \(M\).

For a concise introduction to semialgebraic geometry, we refer the reader to [8] Ch. 2 and [10].

### 2.6. Approximation of holomorphic maps into algebraic varieties.

The following approximation theorem is due to Lempert [19].

**Theorem 2.8** (cf. [19] Thm. 3.2). Let \(\Omega \subset \mathbb{C}^q\) be a Runge domain and let \(\Omega_0 \subset \Omega\) be an open set. Let \(f : \Omega \to \mathbb{C}^p\) be a holomorphic map that satisfies a system of equations \(P(z, f(z)) = 0\), for every \(z \in \Omega\), where \(P : \mathbb{C}^q \times \mathbb{C}^p \to \mathbb{C}^p\) is a polynomial map. Then \(f|_{\Omega_0}\) can be uniformly approximated by a Nash map \(F : \Omega_0 \to \mathbb{C}^p\) satisfying \(P(z, F(z)) = 0\) for every \(z \in \Omega_0\).
2.7. **Convergence of closed sets and holomorphic chains.** Let $U$ be an open set in $\mathbb{C}^q$. By a **holomorphic chain** in $U$ we mean a formal sum $A = \sum_{j \in J} \alpha_j C_j$, where $\alpha_j$ are nonzero integers and $\{C_j\}_{j \in J}$ is a locally finite family of pairwise distinct irreducible analytic subsets of $U$ (see [9], [29]; cf. [4]). The set $\bigcup_{j \in J} C_j$ is called the **support** of $A$ and is denoted by $|A|$, whereas the $C_j$ are called the **components** of $A$ with **multiplicities** $\alpha_j$. The chain $A$ is called **positive** if $\alpha_j > 0$ for all $j \in J$. If all the components of $A$ have the same dimension $n$ then $A$ is called an $n$-chain.

Below we introduce convergence in the sense of holomorphic chains in $U$. To do this, we will need first the notion of the local uniform convergence of closed sets: Let $X$ and $\{X_\nu\}_{\nu \in \mathbb{N}}$ be closed subsets of $U$. We say that the sequence $(X_\nu)$ **converges to $X$ locally uniformly** when the following two conditions hold:

1. For every $a \in X$ there exists a sequence $(a_\nu)$ such that $a_\nu \in X_\nu$ and $a_\nu$ converges to $a$ in the Euclidean topology on $\mathbb{C}^q$.
2. For every compact subset $K$ of $U$ such that $K \cap X = \emptyset$, one has $K \cap X_\nu = \emptyset$ for almost all $\nu$.

Then we write $X_\nu \rightarrow X$. (For the topology of local uniform convergence, see [30].)

Let now $Z$ and $\{Z_\nu\}_{\nu \in \mathbb{N}}$ be **positive $n$-chains** in $U$. We say that the sequence $(Z_\nu)$ **converges to $Z$**, when:

1. $|Z_\nu| \rightarrow |Z|$, and
2. For every regular point $a$ of $|Z|$ and every submanifold $T$ of $U$ of dimension $q - n$ transversal to $|Z|$ at $a$ and such that $\overline{T}$ is compact and $|Z| \cap \overline{T} = \{a\}$, one has $\deg(Z_\nu \cdot T) = \deg(Z \cdot T)$ for almost all $\nu$.

Then we write $Z_\nu \rightarrow Z$. (By $Z \cdot T$ we denote the intersection product of $Z$ and $T$ (see, e.g., [29]).) Observe that the chains $Z_\nu \cdot T$ and $Z \cdot T$ for sufficiently large $\nu$ have finite supports and the degrees are well defined. Recall that for a chain $A = \sum_{j=1}^d \alpha_j \{a_j\}$, $\deg(A) = \sum_{j=1}^d \alpha_j$.

The following lemma from [29] asserts that if $|Z_\nu| \rightarrow |Z|$ then for convergence of chains $Z_\nu \rightarrow Z$ it suffices that the condition (c2) be satisfied on a dense subset of the regular locus of $|Z|$.

**Lemma 2.9.** Let $n \in \mathbb{N}$, and let $Z$ and $\{Z_\nu\}_{\nu \in \mathbb{N}}$ be positive $n$-chains in $U$. If $|Z_\nu| \rightarrow |Z|$, then the following conditions are equivalent:

1. $Z_\nu \rightarrow Z$
2. For every point $a$ from a given dense subset of the regular locus $\text{Reg}(|Z|)$, there exists a submanifold $T$ of $U$ of dimension $q - n$ transversal to $|Z|$ at $a$ and such that $\overline{T}$ is compact, $|Z| \cap \overline{T} = \{a\}$ and $\deg(Z_\nu \cdot T) = \deg(Z \cdot T)$ for almost all $\nu$.

Let now $X$ and $\{X_\nu\}_{\nu \in \mathbb{N}}$ be analytic sets of pure dimension $n$ in an open $U$ in $\mathbb{C}^q$. We say that the sequence $(X_\nu)$ **converges to $X$ in the sense of (holomorphic) chains** when the sequence $(Z_\nu)$ of $n$-chains converges to the $n$-chain $Z$, where $Z$ and $\{Z_\nu\}_{\nu \in \mathbb{N}}$ are obtained by assigning multiplicity 1 to all the irreducible components of $X$ and $\{X_\nu\}_{\nu \in \mathbb{N}}$ respectively.

2.8. **Holomorphic closure.** Finally, let us recall the notion of holomorphic closure. Let $S$ be an arbitrary non-empty subset of $\mathbb{C}^q$ and let $a \in \overline{S}$. By Noetherianity, there exists a smallest (with respect to inclusion) germ of a complex analytic set at $a$ which contains the germ $S_a$. It is called the **holomorphic closure** of $S$ at $a$, and
is denoted $\overline{S}^n_{HC}$. For a systematic study of holomorphic closure of real analytic and semialgebraic sets, see [2] and [1] respectively. Here, we shall only need the following fundamental observation:

**Proposition 2.10** ([11] Prop. 1). The holomorphic closure of a semialgebraic set $S$ at a point $a \in \overline{S}$ is a Nash germ.

### 3. Approximation of analytic sets by Nash sets

We prove in this section our main result, Theorem [11]. We begin with an auxiliary proposition, which can be viewed as a global variant of the Rückert Lemma.

**Proposition 3.1.** Let $\Omega$ be a domain of holomorphy in $\mathbb{C}^q$ and let $X$ be a nonempty irreducible analytic subset of $\Omega$ of dimension $n < q$. Then, there are $g_1, \ldots, g_{q-n}, \ h_1, \ldots, h_p \in \mathcal{O}(\Omega)$ and a nowhere-dense subset $E$ of $X$ such that the following hold:

(i) $X = \{g_1 = \ldots = g_{q-n} = h_1 = \ldots = h_p = 0\}$

(ii) For every $a \in X \setminus E$ there is a neighbourhood $U$ of $a$ in $\Omega$ such that $\{g_1 = \ldots = g_{q-n} = 0\} \cap U = X \cap U$ and $(g_1, \ldots, g_{q-n})|_U$ is a submersion.

**Proof.** First let us prove the following

**Claim.** If $Z$ is an irreducible analytic subset of $\Omega$ such that $X \subsetneq Z$, then for every $\zeta \in \text{Reg}(X) \cap \text{Reg}(Z)$ there is $g \in \mathcal{O}(\Omega)$ such that $X \subset \{g = 0\}$ and $(d\zeta)|_{\text{Reg}(Z)} \neq 0$.

Fix an arbitrary $\zeta \in \text{Reg}(X) \cap \text{Reg}(Z)$. By irreducibility of the sets $X$ and $Z$, one has $\dim_z X < \dim_z Z$ for every $z \in X$. Therefore, there are a neighbourhood $V$ of $\zeta$ in $\Omega$ and $u \in \mathcal{O}(V)$ such that $X \cap V \subset \{u = 0\}$ and $(d\zeta)|_{\text{Reg}(Z)} \neq 0$.

Let $\mathcal{J}(X)$ denote the full sheaf of ideals of $X$ on $\Omega$ (see, e.g., [15]). By Cartan’s Theorem A, the global sections $H^0(\Omega, \mathcal{J}(X))$ generate $\mathcal{J}(X)$ for all $z \in \Omega$ (cf. [15], p. 243). Consequently, there are $f_1, \ldots, f_m \in \mathcal{O}(\Omega)$ with $X \subset \{f_1 = \ldots = f_m = 0\}$ and there are $v_1, \ldots, v_m$ holomorphic in some neighbourhood of $z$ in $\Omega$ such that $u \zeta = u_1 f_1 + \ldots + u_m f_m \zeta$. Since $(d\zeta)|_{\text{Reg}(Z)} \neq 0$, there must be $g \in \{f_1, \ldots, f_m\}$ such that $(d\zeta g)|_{\text{Reg}(Z)} \neq 0$, which completes the proof of the claim.

Let us return to the proof of the proposition. Without loss of generality, one can assume that $\Omega$ is connected. Set $Z_1 = \Omega$. Then, by Claim, there is $g_1 \in \mathcal{O}(\Omega)$ such that $X \subset \{g_1 = 0\}$ and $(d\zeta g_1)|_{\text{Reg}(Z_1)} \neq 0$ for some $\zeta \in \text{Reg}(X) \cap \text{Reg}(Z_1)$. It follows that $\zeta \in \text{Reg}(X) \cap \text{Reg}(Z_1 \cap \{g_1 = 0\})$.

Let $Z_2$ be the irreducible component of $Z_1 \cap \{g_1 = 0\}$ containing $X$. If $q-n > 1$, then $X \subsetneq Z_2$ and $\text{Reg}(X) \cap \text{Reg}(Z_2) \neq \emptyset$. By Claim, there exists $g_2 \in \mathcal{O}(\Omega)$ such that $X \subset \{g_2 = 0\}$ and $(d\zeta g_2)|_{\text{Reg}(Z_2)} \neq 0$ for some $\zeta \in \text{Reg}(X) \cap \text{Reg}(Z_2)$. Then, again, $\zeta_2 \in \text{Reg}(X) \cap \text{Reg}(Z_2 \cap \{g_2 = 0\})$, and hence there exists a unique irreducible component of $Z_2 \cap \{g_2 = 0\}$ containing $X$: call it $Z_3$. If $q-n > 2$, then $X \subsetneq Z_3$ and $\text{Reg}(X) \cap \text{Reg}(Z_3) \neq \emptyset$ and Claim can be applied again. We repeat this procedure until we get $Z_1, Z_2, \ldots, Z_q-n$ and $g_1, g_2, \ldots, g_{q-n}$.

Clearly, $X$ is the unique irreducible component of $Z_{q-n} \cap \{g_{q-n} = 0\}$ containing $X$. Moreover, Theorem [22] implies that there are $h_1, \ldots, h_p \in \mathcal{O}(\Omega)$ such that $X = \{g_1 = g_2 = \ldots = g_{q-n} = h_1 = \ldots = h_p = 0\}$. Set $E = \text{Sing}(X) \cup \bigcup_{j=1}^{q-n} (E_j \cap X)$, where $E_j = \text{Sing}(Z_j) \cup \{z \in \text{Reg}(Z_j) : (d\zeta g_j)|_{\text{Reg}(Z_j)} = 0\}$. By construction, $g_1, \ldots, g_{q-n}$ and $E$ have all the required properties. □
We are now ready to prove our approximation theorem. Let \( \Omega \) be a Runge domain in \( \mathbb{C}^n \), let \( X \) be a complex analytic subset of \( \Omega \) of pure dimension \( n \), and let \( Y \) be a Nash subset of \( \Omega \) with \( Y \subset X \).

**Proof of Theorem 2.1** Fix an open \( \Omega_0 \subset \Omega \). We want to find a sequence \( (X_\nu)_{\nu \in \mathbb{N}} \) of Nash subsets of \( \Omega_0 \) of pure dimension \( n \) converging to \( X \cap \Omega_0 \) in the sense of chains and such that for all \( \nu \).

Since irreducible components of \( X \) can be approximated separately, \( X \) can be assumed irreducible. One can also assume that \( X \) is nonempty and \( X \subsetneq \Omega \). The proof will be divided into three steps according to the properties of the Nash set \( Y \).

**Step 1.** First, suppose that \( Y = \emptyset \).

By Proposition 3.1 we can fix \( g_1, \ldots, g_{q-n}, h_1, \ldots, h_p \in \mathcal{O}(\Omega) \) and a nowhere-dense subset \( E \) of \( X \) with the following properties:

- \( X = \{ g_1 = \ldots = g_{q-n} = h_1 = \ldots = h_p = 0 \} \)
- For every \( a \in X \setminus E \), there is a neighbourhood \( U \) of \( a \) in \( \Omega \) such that \( \{ g_1 = \ldots = g_{q-n} = 0 \} \cap U = X \cap U \) and \( (g_1, \ldots, g_{q-n}) \mid U \) is a submersion.

Let \( \Theta \) be the union of all irreducible components of \( \{ g_1 = \ldots = g_{q-n} = 0 \} \) different from \( X \). By Proposition 2.1 one can choose \( f \in \mathcal{O}(\Omega) \) such that

\[
\Theta \subset \{ f = 0 \} \text{ and } f \text{ does not vanish identically on } X.
\]

Let \( \Omega' \subset \Omega \) be a Runge domain with \( \Omega_0 \Subset \Omega' \). By Corollary 2.5 there is a positive integer \( t \) and there are \( \alpha_{i,j} \in \mathcal{O}(\Omega') \) such that

\[
f^t h^i_j = \sum_{j=1}^{q-n} \alpha_{i,j} g_j, \text{ for } i = 1, \ldots, p,
\]

on \( \Omega' \). Theorem 2.8 implies that there are sequences \( (f_\nu), (h_{i,\nu}), (g_{j,\nu}), \) and \( (\alpha_{i,j,\nu}) \) of Nash functions on \( \Omega_0 \) approximating \( f|_{\Omega_0}, h_i|_{\Omega_0}, g_j|_{\Omega_0}, \) and \( \alpha_{i,j}|_{\Omega_0} \), respectively, and such that, for every \( \nu \in \mathbb{N} \),

\[
f^t h^i_{j,\nu} = \sum_{j=1}^{q-n} \alpha_{i,j,\nu} g_{j,\nu}, \text{ for } i = 1, \ldots, p.
\]

For \( \nu \in \mathbb{N} \), define \( \bar{X}_\nu = \{ g_{1,\nu} = \ldots = g_{q-n,\nu} = h_{1,\nu} = \ldots = h_{p,\nu} = 0 \} \), and let \( X_\nu \) be the \( n \)-dimensional part of \( \bar{X}_\nu \) (i.e., the union of all the \( n \)-dimensional irreducible components of \( X_\nu \)). We shall prove that \( (X_\nu)_{\nu \in \mathbb{N}} \) converges to \( X \cap \Omega_0 \) in the sense of chains.

First let us show that \( (X_\nu) \) converges to \( X \cap \Omega_0 \) locally uniformly (i.e., that (11) and (12) of Section 2.7 are satisfied). The condition (12) is immediate. Indeed, for any compact \( K \subset \Omega_0 \) with \( K \cap X = \emptyset \), we have \( \inf_{z \in K} (\sum_{i=1}^{q-n} |g_i(z)| + \sum_{j=1}^p |h_j(z)|) > 0 \). Consequently, \( \inf_{z \in K} (\sum_{i=1}^{q-n} |g_{i,\nu}(z)| + \sum_{j=1}^p |h_{j,\nu}(z)|) > 0 \) for \( \nu \) large enough, hence \( \bar{X}_\nu \cap K = \emptyset \).

As for (11), the density of \( X \setminus (E \cup \{ f = 0 \}) \) in \( X \) implies that it suffices to check whether for every \( a \in X \setminus (E \cup \{ f = 0 \}) \) there is a sequence \( (a_\nu) \) with \( a_\nu \in X_\nu \) and \( \lim_{\nu \to \infty} a_\nu = a \). Fix \( a \in X \setminus (E \cup \{ f = 0 \}) \), and set \( X'_\nu := \{ g_{1,\nu} = \ldots = g_{q-n,\nu} = 0 \} \), for \( \nu \in \mathbb{N} \). Recall that \( (g_1, \ldots, g_{q-n}) \) is a submersion in some neighbourhood \( V \) of \( a \) such that \( X \cap V = \{ g_1 = \ldots = g_{q-n} = 0 \} \cap V \). Shrinking \( V \) if needed, one can assume that \( (g_1, \ldots, g_{q-n}) \mid V \) is also a submersion, for almost all \( \nu \). For such \( \nu \),
$X'_ν ∩ V$ is then an $n$-dimensional complex analytic manifold and one can readily find a sequence $(a_ν)$, $a_ν ∈ X'_ν$, convergent to $a$. Notice however that $X'_ν ∩ V = X_ν ∩ V$ for $ν$ large enough: Clearly, $X_ν ∩ V ⊆ X'_ν ∩ V$ for any $ν$. On the other hand, it follows from (3.1) that, for $ν$ large enough, we have $f_ν|X'_ν ≠ 0$. For every such $ν$, the $h_{i,ν}$ ($i = 1, . . . , p$) vanish identically on $X'_ν ∩ V$, by (3.3), and hence $X'_ν ∩ V ⊆ X_ν ∩ V$, as required.

To complete the proof of the theorem in the case when $Y = ∅$, it remains to check that $X ∩ Ω_0$ and $(X_ν)_{ν ∈ N}$ satisfy condition (c2) of Section 2.7. By Lemma 2.9 it suffices to show that, for every $a ∈ X \setminus (E ∪ \{f = 0\})$, there exists a submanifold $T$ of $Ω_0$ of dimension $q − n$ transversal to $X$ at $a$ and such that $T$ is compact, $X ∩ T = \{a\}$ and $X_ν ∩ T$ is a singleton for all but finitely many $ν$. Fix a point $a ∈ X \setminus (E ∪ \{f = 0\})$. Choose a neighbourhood $V$ of $a$ in the same way as in the previous paragraph. Let $L$ be the $q − n$ dimensional affine subspace of $C^q$ normal to $X$ at $a$. It is now clear that any sufficiently small open ball $T ⊆ V ∩ L$ centered at $a$ satisfies the above requirements.

Step 2. Suppose now that $Y$ is a Nash set of pure dimension $d$.

Shrinking $Ω$ if necessary, one can assume that $Y$ has finitely many irreducible components. We shall construct a system of equations such that if $g_1, . . . , g_{q − n}, h_1, . . . , h_p$, in addition to (3.3), satisfy that system (together with some other functions), then $Y ∩ Ω_0 ⊆ X_ν$.

By Theorem 2.6 one can choose an algebraic subset $Z$ of $C^q$ of pure dimension $d$ such that $Y$ is the union of certain analytic irreducible components of $Z ∩ Ω$. Let $Σ$ be the union of all analytic irreducible components of $Z ∩ Ω$ which are not contained in $Y$. By Proposition 2.41 there is $f ∈ O(Ω)$ such that

$$\tag{3.4} Σ ⊆ \{f = 0\} \text{ and } f \text{ does not vanish identically}$$

on any irreducible component of $Y$.

Let $g_1, . . . , g_r$ be polynomials in $q$ complex variables such that $Z = \{g_1 = . . . = g_r = 0\}$. Let $g_1, . . . , g_{q − n}, h_1, . . . , h_p$ be the functions describing $X$ and let $Ω′ ⊆ Ω$ be a Runge domain such that $Ω_0 ⊆ Ω′$, as in Step 1 of the proof.

Corollary 2.7 implies that there is an integer $u$ and there are $β_{k,j}, γ_{k,i} ∈ O(Ω′)$ such that, in addition to (3.2), we have

$$\tilde{f}^u g_j^u = \sum_{k=1}^r β_{k,j} g_k, \text{ for } j = 1, . . . , q − n,$$

$$\tilde{f}^u h_i^u = \sum_{k=1}^r γ_{k,i} g_k, \text{ for } i = 1, . . . , p.$$
Then, as proved in Step 1, the $n$-dimensional part $X_\nu$ of $\tilde{X}_\nu = \{g_{1,\nu} = \ldots = g_{q-n,\nu} = h_{1,\nu} = \ldots = h_{p,\nu} = 0\}$ approximates $X \cap \Omega_0$ in the sense of chains. Moreover, by (3.5), $Y \cap \Omega_0 \subset \tilde{X}_\nu$, but we still do not know whether $Y \cap \Omega_0 \subset X_\nu$ for almost all $\nu \in \mathbb{N}$. To ensure the latter inclusion we shall need some additional polynomial relations fulfilled.

First observe that $Y \cap \Omega_0$ can be assumed to have a finite number of analytic irreducible components (if this were not the case, one can replace $\Omega_0$ with a slightly larger polynomial polyhedron which is a relatively compact subset of $\Omega'$). Next, after a linear change of coordinates in $\mathbb{C}^q$ if needed, one can assume that $Z$ as a subset of $\mathbb{C}^q = \mathbb{C}^n \times \mathbb{C}^{q-n}$ has proper projection onto $\mathbb{C}^n$, and that for every analytic irreducible component $\hat{Y}$ of $Y \cap \Omega_0$ there is a polydisc $D_1 \times D_2 \subset \Omega_0 \subset \mathbb{C}^n \times \mathbb{C}^{q-n}$ such that $\hat{Y} \cap (D_1 \times D_2) \neq \emptyset$ and $X \cap (D_1 \times D_2)$ has proper projection onto $D_1$.

Let $\hat{Z}$ denote the image of the projection of $Z$ onto $\mathbb{C}^n$. Clearly, $\hat{Z}$ is an algebraic set of pure dimension $d$ and there are polynomials $w_1, \ldots, w_s$ in $n$ complex variables such that $\hat{Z} = \{w_1 = \ldots = w_s = 0\}$. Let $\hat{X} \subset \Omega$ denote the $d$-dimensional part of $X \cap (\hat{Z} \times \mathbb{C}^{q-n})$.

By Step 1 of the proof, we know that $\hat{X} \cap \Omega_0$ can be approximated by Nash subsets of $\Omega_0$ of pure dimension $d$. More precisely, there are polynomials $Q_1, \ldots, Q_N$ and there are $F_1, \ldots, F_M, \tau_1, \ldots, \tau_R \in \mathcal{O}(\Omega)$ such that:

- $\hat{X} = \{F_1 = \ldots = F_M = 0\}$ and $Q_j(F_1, \ldots, F_M, \tau_1, \ldots, \tau_R) = 0$ for $j = 1, \ldots, N$.
- For all sequences $(F_{1,\nu}), \ldots, (F_{M,\nu}), (\tau_{1,\nu}), \ldots, (\tau_{R,\nu})$ of Nash functions on $\Omega_0$ approximating the restrictions $F_1|_{\Omega_0}, \ldots, F_M|_{\Omega_0}, \tau_1|_{\Omega_0}, \ldots, \tau_R|_{\Omega_0}$, respectively, and such that $Q_j(F_{1,\nu}, \ldots, F_{M,\nu}, \tau_{1,\nu}, \ldots, \tau_{R,\nu}) = 0$ for $j = 1, \ldots, N$, the $d$-dimensional parts of the sets $\{F_{1,\nu} = \ldots = F_{M,\nu} = 0\}$ approximate $\hat{X} \cap \Omega_0$ in the sense of chains.

By Proposition 2.1 one can choose $\hat{F} \in \mathcal{O}(\Omega)$ with the following properties: $\hat{F}$ vanishes identically on every irreducible component $S$ of $X \cap (\hat{Z} \times \mathbb{C}^{q-n})$ with $S \not\subset \hat{X}$, and $\hat{F}$ does not vanish identically on any irreducible component of $\hat{X}$. Corollary 2.3 then implies that there is an integer $v$ and there are $G_{i,j}, H_{l,i}, W_{l,k} \in \mathcal{O}(\Omega')$ such

\begin{equation}
\hat{F}^v F_l^v = \sum_{i=1}^{q-n} G_{i,j} g_j + \sum_{i=1}^{p} H_{l,i} h_i + \sum_{k=1}^{s} W_{l,k} w_k, \text{ for } l = 1, \ldots, M.
\end{equation}

By Theorem 2.5 there are Nash approximations of all the functions which we have approximated so far satisfying (3.3) and (3.5), and there are Nash approximations $(\hat{F}_\nu), (F_{1,\nu}), (\tau_{1,\nu}), \ldots, (\tau_{R,\nu}), (G_{i,j,\nu}), (H_{l,i,\nu}),$ and $(W_{l,k,\nu})$ of $\hat{F}|_{\Omega_0}, F_1|_{\Omega_0}, \tau_1|_{\Omega_0}, \ldots, \tau_R|_{\Omega_0}, G_{i,j}|_{\Omega_0}, H_{l,i}|_{\Omega_0},$ and $W_{l,k}|_{\Omega_0}$, respectively, such that

\begin{equation}
Q_j(F_{1,\nu}, \ldots, F_{M,\nu}, \tau_{1,\nu}, \ldots, \tau_{R,\nu}) = 0 \text{ for } j = 1, \ldots, N,
\end{equation}

and

\begin{equation}
\hat{F}_{\nu}^v F_{l,\nu}^v = \sum_{j=1}^{q-n} G_{i,j,\nu} g_{j,\nu} + \sum_{i=1}^{p} H_{l,i,\nu} h_{i,\nu} + \sum_{k=1}^{s} W_{l,k,\nu} w_k, \text{ for } l = 1, \ldots, M.
\end{equation}

We claim now that $Y \cap \Omega_0$ is contained in the $n$-dimensional part $X_\nu$ of $\tilde{X}_\nu = \{g_{1,\nu} = \ldots = g_{q-n,\nu} = h_{1,\nu} = \ldots = h_{p,\nu} = 0\}$ for $\nu$ large enough. Suppose that this is not the case. Then, one can choose an irreducible component $\hat{Y}$ of $Y \cap \Omega_0$ which is not contained in $X_\nu$ for infinitely many $\nu \in \mathbb{N}$. 
For this \( \hat{Y} \), choose a polydisc \( D_1 \times D_2 \subset \Omega_0 \subset \mathbb{C}^n \times \mathbb{C}^{q-n} \) as above. Then \( \hat{Y} \cap (D_1 \times D_2) \neq \emptyset \) and \( X \cap (D_1 \times D_2) \) has proper projection onto \( D_1 \). Shrinking \( D_1 \) and \( D_2 \) if needed, one can additionally assume that \( \hat{Z} \cap D_1 \) is a connected \( d \)-dimensional complex analytic manifold, that \( X \cap (\hat{Z} \times \mathbb{C}^{q-n}) \cap (D_1 \times D_2) = \hat{Y} \cap (D_1 \times D_2) \), and that \( \hat{Y} \cap (D_1 \times D_2) \) is a manifold such that over every point in \( \hat{Z} \cap D_1 \) there is precisely one point in \( \hat{Y} \cap (D_1 \times D_2) \).

Finally, we may assume that \( \inf_{D_1 \times D_2} |\bar{F}| > 0 \). Indeed, since \( \hat{Y} \cap (D_1 \times D_2) \) is of pure dimension \( d \), it follows that \( X \cap (\hat{Z} \times \mathbb{C}^{q-n}) \cap (D_1 \times D_2) = \hat{X} \cap (D_1 \times D_2) \). But \( \bar{F} \) does not vanish identically on any irreducible component of \( \hat{X} \), so shrinking \( D_1 \times D_2 \) we get \( \inf_{D_1 \times D_2} |\bar{F}| > 0 \).

Set \( \hat{E}_\nu := X_\nu \cap (\hat{Z} \times \mathbb{C}^{q-n}) \cap (D_1 \times D_2) \). Now, by (3.5), we know that \( \hat{Y} \cap (D_1 \times D_2) \subset \hat{E}_\nu \) for \( \nu \) large enough. Note also that each \( X_\nu \) (for \( \nu \) large enough) has irreducible components of dimension at most \( n \). Therefore, if \( \hat{Y} \not\subset X_\nu \), then over a generic point in \( \hat{Z} \cap D_1 \) there are at least two points in \( \hat{E}_\nu \).

On the other hand, by the fact that \( \inf_{D_1 \times D_2} |\bar{F}_\nu| > 0 \) for \( \nu \) large enough, and by (3.3), we have \( \hat{E}_\nu \subset \{ F_1, \ldots = F_M, \nu = 0 \} \cap (D_1 \times D_2) \). Consequently, the \( d \)-dimensional part of \( \{ F_1, \ldots = F_M, \nu = 0 \} \cap (D_1 \times D_2) \) does not converge to \( \{ F_1 = \ldots = F_M = 0 \} \cap (D_1 \times D_2) = \hat{Y} \cap (D_1 \times D_2) \) in the sense of chains; a contradiction.

**Step 3.** Now, let \( Y \) be an arbitrary Nash subset of \( \Omega \) contained in \( X \). Let \( Y = Y_0 \cup \ldots \cup Y_{\dim(Y)} \) be the equidimensional decomposition of \( Y \). Fix \( j \in \{0, \ldots, \dim(Y)\} \). By Step 2 of the proof, there is a system \( (T_j) \) of polynomial equations satisfied by a system \( (s) \) of holomorphic functions, such that:

- \( (s) \) contains the functions \( g_1, \ldots, g_{q-n}, h_1, \ldots, h_p \)
- For every system \( (s_\nu) \) of Nash functions sufficiently close to those from \( (s) \) on \( \Omega_0 \), and satisfying \( (T_j) \), the following holds: The \( n \)-dimensional part \( X_\nu \) of \( X_\nu = \{ g_1, \ldots = g_{q-n}, h_1, \ldots = h_p, \nu = 0 \} \) approximates \( X \cap \Omega_0 \) and \( Y_j \cap X_\nu (\nu \in \mathbb{N}) \), where \( g_1, \ldots, g_{q-n}, h_1, \ldots, h_p, \nu \) are Nash functions from \( (s_\nu) \) approximating \( g_1, \ldots, g_{q-n}, h_1, \ldots, h_p, \) respectively, on \( \Omega_0 \).

Theorem [2,8] allows one to approximate the systems of functions simultaneously for all \( j \in \{0, \ldots, \dim(Y)\} \) in such a way that the corresponding systems of polynomial equations are satisfied, which implies that we can obtain the sequence \( (X_\nu)_{\nu \in \mathbb{N}} \) with all the required properties.

\[ \square \]

4. **Geometric obstruction to Nash approximation along a subset**

In the present section, we study the question of Nash approximation of a complex analytic set along its arbitrary subset. Our interest originally developed from considerations of pairs \( (X, R) \) of a complex analytic set \( X \) and its real analytic subset \( R \), but it turned out that the approximation question is independent of the real analytic structure of \( R \). Instead, it depends on the holomorphic closure of \( R \). The following proposition characterizes a local geometric obstruction to Nash approximation.

**Proposition 4.1.** Let \( X \) be a complex analytic subset of an open set \( U \) in \( \mathbb{C}^n \), and let \( R \) be an arbitrary subset of \( X \). For every point \( a \in R \), the following conditions are equivalent:

- \( a \) is a Nash point of \( X \)
- \( a \) is a Nash point of \( X \setminus \text{sing}(X) \)
- \( a \) is a Nash point of \( X \setminus \text{sing}(X) \cap R \)
- \( a \) is a Nash point of \( X \setminus \text{sing}(X) \cap R \)
(i) There is an open neighbourhood $V$ of $a$ in $U$ and a sequence $(X_\nu)_{\nu=1}^\infty$ of Nash sets in $V$ locally uniformly convergent to $X \cap V$ and such that $X_\nu \supset R \cap V$ for all $\nu$.

(ii) There is a semialgebraic germ $S_a$ at $a$ such that $R_a \subset S_a \subset X_a$.

(iii) There is a Nash germ $Y_a$ at $a$ such that $R_a \subset Y_a \subset X_a$.

Proof. For the implication (i) $\Rightarrow$ (ii), suppose that $V$ is an open neighbourhood of $a$ in $U$ and $(X_\nu)_{\nu=1}^\infty$ is a sequence of Nash sets in $V$ convergent to $X \cap V$ locally uniformly on $V$, and such that $X_\nu \supset R \cap V$ for all $\nu$. We will show that there exists a Nash set $Y$ in $V$ such that $R_a \subset Y_a \subset X_a$.

For a proof by contradiction suppose there is no such $Y$. Then the smallest (with respect to inclusion) Nash subset of $V$ containing $R \cap V$, call it $Z$, is not a subset of $X \cap V$. On the other hand, for every $\nu$, $X_\nu \cap Z$ is a Nash subset of $V$ containing $R \cap V$. We claim that, for $\nu$ large enough, $X_\nu \cap Z$ is a proper subset of $Z$, thus contradicting the minimality of $Z$. Indeed, choose a point $b \in Z \setminus X$. The set $X$ being closed in $U$, there is a positive $\epsilon$ such that $B_\epsilon(b) \cap X = \emptyset$, where $B_\epsilon(b)$ denotes the Euclidean ball with radius $\epsilon$ centered at $b \in C^\infty$. The problem being local, one can assume without loss of generality that $(X_\nu)$ converges to $X \cap V$ in the sense of Hausdorff metric (cf. [22] and Section 2.4). Hence, for $\nu$ large enough, the Hausdorff distance between $X \cap V$ and $X_\nu$ is less than $\epsilon/2$, and so $B_2(\epsilon)(b) \cap X_\nu = \emptyset$ for all such $\nu$. In particular, $b \in Z \setminus X$, so that $X_\nu \cap Z \subset Z$.

The implication (iii) $\Rightarrow$ (ii) is immediate, since every Nash germ is a germ of a semialgebraic set, by [3] Prop. 8.1.8.

As for (ii) $\Rightarrow$ (i), suppose that there is a semialgebraic germ $S_a$ at $a$ such that $R_a \subset S_a \subset X_a$. By Proposition 2.10 the holomorphic closure of $S_a$ is a Nash germ, say $Y_a$. Since, by definition, $Y_a$ is the smallest complex analytic germ containing $S_a$, it follows that $Y_a \subset X_a$. In other words, locally near $a$, $R$ is contained in a Nash subset $Y$ of $X$. Now, by Theorem 1.1 (in fact, here it suffices to use [3] Thm. 1.1), there exists a neighbourhood $V$ of $a$ in $U$ and a sequence $(X_\nu)_{\nu=1}^\infty$ of Nash subsets of $V$ convergent locally uniformly to $X \cap V$ and such that $X_\nu \supset Y \cap V$ for all $\nu$; hence property (i) holds.

Let us now turn to the proof of Theorem 1.2. As asserted by the theorem, the global obstruction to Nash approximation of a complex analytic set along its arbitrary subset is of the same nature as the local one.

Proof of Theorem 1.2. We shall prove that the following sequence of implications holds: (i) $\Rightarrow$ (ii) $\Rightarrow$ (v) $\Rightarrow$ (vi) $\Rightarrow$ (iv) $\Rightarrow$ (iii) $\Rightarrow$ (i).

The implications (i) $\Rightarrow$ (ii) and (v) $\Rightarrow$ (vi) are trivial. As for (vi) $\Rightarrow$ (iv), it is an immediate consequence of the fact that every Nash germ is a germ of a semialgebraic set, by [3] Prop. 8.1.8.

For the proof of (iv) $\Rightarrow$ (iii), fix a relatively compact open subset $\Omega_0$ of $\Omega$. Under the assumptions of (iv) one can find a finite open covering $\{V_1, \ldots, V_s\}$ of $\Omega_0$ such that, for every $j = 1, \ldots, s$, $V_j$ contains a subset $S_j$ semialgebraic and satisfying $R \cap V_j \subset S_j \subset X \cap V_j$. Then $S = S_1 \cup \cdots \cup S_s$ is a required semialgebraic set.

The implication (iii) $\Rightarrow$ (i) follows from Theorem 1.1 and Proposition 1.2 below. Finally, for the proof of (ii) $\Rightarrow$ (v), we proceed by contradiction: Suppose that there is an open $\Omega_0 \subset \Omega$ such that no Nash subset of $\Omega_0$ which contains $R \cap \Omega_0$ is contained in $X$. Let $Z$ be the smallest (with respect to inclusion) Nash subset of
Ω₀ which contains \( R \cap Ω₀ \). Then \( Z \not\subset X \cap Ω₀ \). Now, let \( (X_ν)_{ν=1}^{∞} \) be a sequence of Nash subsets of Ω₀ that exists by property (ii) of the theorem. As in the proof of Proposition 4.1, one shows that for \( ν \) large enough the set \( X_ν \cap Z \) is a Nash subset of \( Ω₀ \) containing \( R \cap Ω₀ \) and properly contained in \( Z \). This contradicts the choice of \( Z \), which completes the proof of the theorem. □

The following result is a global analogue of Proposition 2.10.

**Proposition 4.2.** Let \( Ω \) be an open subset of \( C^q \) and let \( X \) be complex analytic in \( Ω \). For every semialgebraic \( S \) contained in \( X \), there exists a Nash set \( Y \) in \( Ω \) such that \( S \subset Y \subset X \).

**Proof.** By semialgebraic stratification (Remark 2.7(2)), it suffices to consider the case when \( S \) is a semialgebraic connected real analytic closed submanifold of an open subset of \( Ω \). Then, by Proposition 2.10, there exist an open set \( V \subset Ω \) and an irreducible Nash subset \( N \) of \( V \), such that \( S \cap V \) is a nonempty connected manifold and \( S \cap V \subset N \subset X \). By Theorem 2.6, one can choose an irreducible complex algebraic set \( Z \) in \( C^q \) such that \( N \subset Z \) and \( \dim N = \dim Z \). By irreducibility of \( N \), there exists a unique analytic irreducible component of \( Z \cap Ω \) which contains \( N \); call it \( Y \). Then, by Theorem 2.6 again, \( Y \) is a Nash set. Moreover, we have \( S \subset Y \subset X \). Indeed, \( Y \) is an irreducible complex analytic set whose nonempty open subset contains a nonempty open subset of \( S \) and is contained in \( X \). The inclusions thus follow from the Identity Principle. □

**Remark 4.3.** The above proposition is closely related to the problem of finding a global holomorphic closure of a given set. It is important to notice that in Proposition 4.2, one cannot expect that \( S_a^{HC} = Y_a \) at every point \( a \in S \). That is, in general, it may happen that \( S_a^{HC} \) is a proper subgerm of \( Y_a \) at some \( a \in S \), for every choice of a Nash set \( Y \) satisfying the conclusion of the proposition, as can be seen in the following example. On the other hand, if in addition \( S \) is coherent, then its global holomorphic closure exists in some neighbourhood of \( S \) (that is, possibly after shrinking \( Ω \)), by [23, Thm. 1.1].

**Example 4.4.** Let \( ϕ : C \setminus \{±i\} \to C^2 \) be given as

\[
ϕ(ζ) = \left( \frac{ζ^2 - 1}{ζ^2 + 1}, \frac{2ζ(ζ^2 - 1)}{(ζ^2 + 1)^2} \right).
\]

Set \( S' := \{ζ = x + iy : (x - 4/3)^2 + y^2 = 1/9\} \), and \( S := ϕ(S') \). Then \( S \) is a connected irreducible (even smooth) semialgebraic real analytic set in \( C^2 \), and since \( ϕ \) parametrizes the irreducible algebraic curve

\[
Y = \{(z, w) \in C^2 : z^4 - z^2 + w^2 = 0\},
\]

it follows that \( Y \) is the smallest Nash subset of \( Ω = C^2 \) that contains \( S \). However, the germ \( Y_{(0,0)} \) consists of two irreducible components and only one of them is the holomorphic closure of \( S_{(0,0)} \).

As an example of application of Proposition 4.2 and Theorem 1.2, we give here a criterion for existence of approximations of a holomorphic map along a given subset of its domain. For \( w = (w_1, \ldots, w_m) \in C^m \), set \( ||w|| = \max_{j=1,\ldots,m} |w_j| \).
Theorem 4.5. Let $U$ be a Runge domain in $\mathbb{C}^n$, let $F : U \to \mathbb{C}^m$ be a holomorphic mapping, and let $A$ be an arbitrary subset of $U$. The following conditions are equivalent:

(i) For every open $V \subseteq U$ and $\epsilon > 0$, there exists a Nash mapping $H : V \to \mathbb{C}^m$ which coincides with $F$ on $A \cap V$ and such that $\|H(z) - F(z)\| < \epsilon$ for all $z \in V$.

(ii) For every open $V \subseteq U$, there exist a semialgebraic set $T$ with $A \cap V \subset T \subset U$ and a semialgebraic mapping $G : T \to \mathbb{C}^m$ such that $F|_T \equiv G$.

Proof. Set $\Omega := U \times \mathbb{C}^m$, $X := \{(z, F(z)) : z \in U\}$, and $R := \{(z, F(z)) : z \in A\}$. Clearly, $X$ is of pure dimension $n$. Given an open $V$ relatively compact in $U$, there is $M_V > 0$ such that $\|F(z)\| < M_V$ for all $z \in V$, and so

$$\Omega_V := V \times \{w = (w_1, \ldots, w_m) \in \mathbb{C}^m : |w_j| < M_V, j = 1, \ldots, m\}$$

is a relatively compact open subset of $\Omega$.

With this terminology, condition (ii) of the theorem is now equivalent to saying that for every $\Omega_V$ as above there is a semialgebraic set $S$ such that $R \cap \Omega_V \subset S \subset X$. The implication (ii) $\Rightarrow$ (i) thus follows from Proposition 4.2 and [25, Thm. 3.6]. (Of course, it could be also derived from Theorem 1.1.)

Condition (i), on the other hand, implies that for every open $\Omega_0 \subseteq \Omega$, $X \cap \Omega_0$ can be approximated locally uniformly along $R \cap \Omega_0$ by a sequence $(X_\nu)_{\nu \in \mathbb{N}}$ of Nash subsets of $\Omega_0$ of pure dimension $n$. Therefore, (i) $\Rightarrow$ (ii) is a consequence of the implication (ii) $\Rightarrow$ (iii) in Theorem 1.2. $\square$

Theorem 4.5 can be used, in particular, for Nash approximation of holomorphic extensions of a given map. Indeed, the theorem characterizes those pairs $(F, f)$ of a holomorphic extension $F$ of a given map $f$ for which $F$ can be approximated by Nash mappings each of which extends $f$.

Acknowledgements

We would like to thank Professor Marek Jarnicki for pointing out the division theorem in Section 2.3 as an elegant tool for deriving the global Nullstellensatz on domains of holomorphy. We are also grateful to Professor Rasul Shafikov for stimulating discussions.
