1. Introduction

Since the second half of the twentieth century, nonlinear science has made great development. Chaos, as a research hotspot of nonlinear science, is considered to be the third revolution after relativity theory and quantum mechanics [1]. So, it is paid more attention by many researchers. They found some important properties about different kinds of chaotic systems, especially including chaotic systems with hidden attractors [2–6]. These attractors are widely present in different dynamic systems, such as the Chua circuit [7], Van der Pol–Duffing oscillator [8], induction motor-driven drilling system model [9], convective fluid motion-like Lorenz system [10], and multilevel DC converter [11]. Hidden attractors are not intersected with any small neighborhoods of unstable equilibrium points, which can lead to unpredictable catastrophic responses, such as airplane crashes, sudden climate changes, severe diseases, financial crises, and commercial equipment problems [12, 13]. Therefore, the research studies on chaotic control of the systems with hidden attractors are of great significance. Sharma et al. [14] applied the scheme of linear augmentation to control the multistability in the hidden attractors. Feng and Wei [15] studied time-delay feedback control to the generalized Sprott B system with hidden attractors. Adaptive control of the hyperchaotic system with a hidden attractor was designed by Vaidyanathan [16]. Wei et al. [17] applied the nonlinear feedback controller, sliding mode controller, and their hybrid combination to control the chaotic system with hidden attractors. In circuits [18–22], Lai et al. proposed a no-equilibrium chaotic system with hidden attractors and coexisting attractors [22]. Marius and Michal [23] proved that the impulsive difference equation can generate hidden attractors; they also restrained the chaotic behavior of one-dimensional discrete dynamical systems by using pulse control. The construction of multiple hidden attractors was achieved by Wu et al. [24] through a universal pulse control. In [25], a sliding mode controller was used to control a three-dimensional multistate time-delay chaotic system with hidden attractors.

About the control of chaotic systems with hidden attractors, the traditional control strategies have already achieved the above research studies. Recently, many control methods have been introduced into chaotic systems, such as energy information. The Hamiltonian energy functions of some classical chaotic systems were calculated and verified by Sarasola [26–28]. In 2005, Sarasola et al. [29] proposed chaotic systems with phase-space variable functions and
analyzed the energy flow under different coupling intensities. Torrealdea et al. [30, 31] described the energy function of a Hindmarsh–Rose neuron and evaluated the energy consumption of the neuron during its signal activity. The energy effect on synchronization for a pair of structurally flexible coupled neurons was studied by Mouajhid et al. [32]. In [33], the Hamilton energy function of Hindmarsh–Rose neurons was calculated. Wang Chun-Ni et al. [34] extended the Helmholtz theorem [35] in the electromagnetic field theory to dimensionless dynamic systems. Li and Yao [36] analyzed the Hamilton energy of a multivolume attractor chaotic system. Ma et al. [37] designed the Hamilton energy function for three types of attractors and studied the energy modulation of the attractor.

Compared with the general chaotic system, the dynamic behavior of the chaotic system with hidden attractors is more complicated. So, the energy consumption is more, and the Hamilton energy value is lower. In order to obtain the better control effect for the chaotic system with hidden attractors, this paper regards the expected minimum energy consumption as a controller target to control chaotic state of the system. Based on the above analysis, this paper constructs a new dynamic system without equilibrium points and calculates the Hamilton energy function through the Helmholtz theorem, and then an energy feedback controller is designed to control the chaotic system by reducing the energy consumption.

The structure of this article is as follows. The dynamic behavior of the chaotic system with hidden attractors is analyzed in the second part. In the third part, we calculate the Hamiltonian energy function of the improved system and design the system controller. In the fourth part, we do the numerical simulations in order to verify the theoretical results. Conclusions are given in the last part.

2. Chaotic System with Hidden Attractors

2.1. Model Building. A chaotic system with special properties can be obtained as follows:

\[
\begin{align*}
\dot{x} &= x, \\
\dot{y} &= -x + ayz + b \cos z, \\
\dot{z} &= c - y^2,
\end{align*}
\]  

(1)

where \(x, y,\) and \(z\) are all state variables and \(a, b,\) and \(c\) are positive real numbers. So, equation (1) is a system with hidden attractors. When \(a = 15, b = 0.01,\) and \(c = 1,\) the phase trajectories of system (1) are shown in Figure 1.

2.2. Dynamic Analysis. For system (1), the divergence [38] is as follows:

\[
\nabla V = \frac{\partial \dot{x}}{\partial x} + \frac{\partial \dot{y}}{\partial y} + \frac{\partial \dot{z}}{\partial z} = 1 + az.
\]  

(2)

When \(-1 - az < 0,\) system (1) is dissipative. It converges in exponential form \((dv/dt) = e^{-(1+az)t},\) which means that a volume element with an initial volume \(V(0)\) converges to a volume element \(V(t)e^{-(1+az)t}\) at time \(t.\) Therefore, when \(t \to +\infty,\) each small volume element including the trajectories of the system converges to zero at an exponential rate \(-1 - az.\) At this time, the trajectories of system (1) will eventually be limited to a set of limit points. Its asymptotic dynamical behavior will be fixed on an attractor. As the system parameters are changed, different states will appear. To set the initial condition as \((0.1, 0.1, 0.1),\) the largest Lyapunov exponent is shown in Figures 2(a) and 2(b) as the parameters \(a\) and \(b\) are changed, respectively. The Lyapunov exponent of system (1) is shown in Figure 2(c). From Figures 2 and 3, we can find that, as \(\lambda_1 = 0, \lambda_2 < 0,\) and \(\lambda_3 < 0,\) system (1) is in the periodic state. When \(\lambda_1 > 0,\) \(\lambda_2 = 0,\) and \(\lambda_3 < 0,\) system (1) is in the chaotic state.

3. Hamilton Energy Control

3.1. Hamilton Energy Theory. Helmholtz theorem decomposes any electromagnetic field into the superposition of the gradient field and vortex field, and the field equation satisfies

\[
F(\vec{r}) = F_d(\vec{r}) + F_v(\vec{r}) = -\nabla \phi(\vec{r}) + \nabla \times \mathbf{A}(\vec{r}),
\]  

(3)

where \(F_d(\vec{r})\) is the gradient field, \(F_v(\vec{r})\) is the vortex field, \(-\nabla \phi(\vec{r})\) is the negative gradient, \(\nabla\) is a vector differential operator, and \(\mathbf{A}(\vec{r})\) is the vector function. Equation (3) is expressed as any field, which can be decomposed into the negative gradient and the curl. It can be converted into the following equation:

\[
\dot{X} = \frac{dX}{dt} = F_v(\vec{r}) + F_d(\vec{r}),
\]  

(4)

where \(X = [x_1, x_2, x_3, \ldots, x_n]\) is a system variable. Therefore, generalized dynamic systems can be used to discuss the Hamilton energy [34] solution of general continuous dynamic systems in this paper. Based on the mean-field theory, the variable evolution of the \(n\)-dimensional dynamic system can be represented by the dynamic equation system of \(n\) variables:

\[
\begin{pmatrix}
\dot{x}_1 \\
\dot{x}_2 \\
\vdots \\
\dot{x}_n
\end{pmatrix} =
\begin{pmatrix}
\frac{\partial F_1(X)}{\partial x_1} & \frac{\partial F_1(X)}{\partial x_2} & \cdots & \frac{\partial F_1(X)}{\partial x_n} \\
\frac{\partial F_2(X)}{\partial x_1} & \frac{\partial F_2(X)}{\partial x_2} & \cdots & \frac{\partial F_2(X)}{\partial x_n} \\
\vdots & \vdots & \ddots & \vdots \\
\frac{\partial F_n(X)}{\partial x_1} & \frac{\partial F_n(X)}{\partial x_2} & \cdots & \frac{\partial F_n(X)}{\partial x_n}
\end{pmatrix}
\begin{pmatrix}
x_1 \\
x_2 \\
\vdots \\
x_n
\end{pmatrix}
\]

\[
= F_v(X) + F_d(X).
\]  

(5)

Suppose the Hamilton energy function of dimensionless dynamic system (5) is \(H,\) so the Hamilton energy function \(H\) satisfies the following conditions:
Figure 1: Phase trajectories for system (1), $a = 15$, $b = 0.01$, and $c = 1$.

Figure 2: Continued.
Figure 2: Lyapunov exponents for system (1). (a) $b = 0.01$ and $c = 1$. (b) $a = 15$ and $c = 1$. (c) $a = 15$, $b = 0.01$, and $c = 1$.

Figure 3: Bifurcation diagram of the variable $y$ for system (1), $a = 15$ and $c = 1$. 
the direction of $\nabla H$ is vertical to the direction of the vortex field.

The three-variable system is

$$
\begin{align*}
\dot{x} &= f_1(x, y, z), \\
\dot{y} &= f_2(x, y, z), \\
\dot{z} &= f_3(x, y, z).
\end{align*}
$$

The corresponding matrix equation is

$$
\begin{pmatrix}
\frac{\partial f_1(x, y, z)}{\partial x} & \ldots & \frac{\partial f_1(x, y, z)}{\partial z} \\
\vdots & \ddots & \vdots \\
\frac{\partial f_3(x, y, z)}{\partial x} & \ldots & \frac{\partial f_3(x, y, z)}{\partial z}
\end{pmatrix}
\begin{pmatrix}
x \\
y \\
z
\end{pmatrix}
= F_c + F_d.
$$

The dimensionless Hamilton energy function satisfies

$$
\begin{align*}
\nabla H^T F_c(X) &= 0, \\
\nabla H^T F_d(X) &= H = \frac{dH}{dt}
\end{align*}
$$

where $F_d(X)$ is the gradient field, $F_c(X)$ is the vortex field, and $J(X)$ and $R(X)$ are the quasi-symmetric matrix and symmetric matrix, respectively. The direction of $\nabla H$ is vertical to the direction of the vortex field.

The three-variable system is

$$
\begin{align*}
\dot{x} &= f_1(x, y, z), \\
\dot{y} &= f_2(x, y, z), \\
\dot{z} &= f_3(x, y, z).
\end{align*}
$$

The corresponding matrix equation is

$$
\begin{pmatrix}
\frac{\partial f_1(x, y, z)}{\partial x} & \ldots & \frac{\partial f_1(x, y, z)}{\partial z} \\
\vdots & \ddots & \vdots \\
\frac{\partial f_3(x, y, z)}{\partial x} & \ldots & \frac{\partial f_3(x, y, z)}{\partial z}
\end{pmatrix}
\begin{pmatrix}
x \\
y \\
z
\end{pmatrix}
= J(X)\nabla H,
$$

$$
\begin{pmatrix}
\frac{\partial f_1(x, y, z)}{\partial x} & \ldots & 0 \\
\vdots & \ddots & \vdots \\
0 & \ldots & \frac{\partial f_n(x, y, z)}{\partial x}
\end{pmatrix}
\begin{pmatrix}
x_1 \\
x_2 \\
\vdots \\
x_n
\end{pmatrix}
= R(X)\nabla H,
$$

$$
dH = F \cdot d\nabla = Fdx + F_y dy + F_z dz = \nabla H \cdot d\nabla,
$$

$$
\begin{pmatrix}
\frac{\partial H}{\partial x} & \frac{\partial H}{\partial y} & \frac{\partial H}{\partial z}
\end{pmatrix}
\begin{pmatrix}
dx \\
dy \\
dz
\end{pmatrix}
= \nabla H^T F_c + \nabla H^T F_d
$$

$$
\begin{pmatrix}
\dot{x} \\
\dot{y} \\
\dot{z}
\end{pmatrix}
= \nabla H^T F_c + \nabla H^T F_d = \nabla H^T F_c = \nabla H^T F_d.
$$

3.2. Hamilton Energy Function for System (1). According to equation (5), the Hamilton energy of system (1) for $F_c = \begin{pmatrix} 0 & -x \cos z \\ -x + b \cos z & c - y^2 \end{pmatrix}$ and $F_d = \begin{pmatrix} x & ayz \\ c & 0 \end{pmatrix}$ can be written as
As we choose parameters \( a = 10, \ b = 0.01, \) and \( c = 1, \) the response and Hamilton energy function are shown in Figures 6(a) and 6(b), respectively. From Figure 6, we can find a brief chaotic process. At the critical moment of state transition, it enters into a period-like motion state at \( t = 120 \) with more energy consumption. From the above analysis, we can see that the more complex the behavior of the system is, the more the consumption of the energy is. At the same time, the Hamilton energy function value is lower.

It can be seen from equation (13) that Hamilton energy depends on the variables and parameters of the system. The evolution of different states for the system has a great influence on the Hamilton energy function. On the contrary, the change of the Hamilton energy function will also affect the behavior of the chaotic system. Therefore, Hamilton energy control can be applied to control the dynamic behavior in system (1).

The controlled system describing Hamilton energy control is as follows:

\[
\begin{align*}
\dot{x} &= x, \\
\dot{y} &= -x + ay + b \cos z, \\
\dot{z} &= c - y^2 - kH, \\
\dot{H} &= -xz - acy + ay^3z,
\end{align*}
\]

where the parameter \( k \) is the feedback coefficient to control the energy flow and \( H \) is the Hamilton energy function of system (1). This method controls the dynamic system by increasing or decreasing the parameter \( k \) to explore the state change of system (1).

4. Numerical Simulations

4.1. Hamilton Energy Feedback Control Simulation. The parameters \( a = 15, \ b = 0.02, \) and \( c = 1, \) and \( k \) is equal to \(-0.07, 0.04, \) and \( 0.18, \) respectively; the time history diagrams for system (15) are shown in Figure 7.

Comparing the results of Figure 7, it can be seen that, by changing \( k, \) the system (1) can be controlled from a chaotic state to an ideal periodic state. Obviously, the Hamilton energy control method is effective. Contrasting the results of Figures 7(b) and 7(c), it can be found that to select the appropriate parameter \( k, \) we can rapidly and effectively control chaos within a limited time.

4.2. Comparison Simulation. In this subsection, the system parameters are chosen as \( a = 15, \ b = 0.01, \) and \( c = 1 \) and the initial condition as \( (0.1, 0.1, 0.1). \) Linear feedback control is the most common control method for studying chaotic systems. This control method is applied to system (1). Let the controller of the system be \( u = (u_1, u_2, u_3)^T, \) and add the controller to system (1); then, the control system is as follows:

\[
\begin{align*}
\dot{x} &= x + u_1, \\
\dot{y} &= -x + ay + b \cos z + u_2, \\
\dot{z} &= c - y^2 + u_3.
\end{align*}
\]
According to system (16), the phase trajectories and time history diagram of the system with the linear feedback controller can be obtained in Figure 8. When $u_1 = 0$, $u_2 = -0.02$, and $u_3 = 0$, the amplitude of the limit cycle is getting smaller and smaller, which shows that the linear control has a certain impact on system (1).

Figures 9(a) and 9(b) are the phase trajectories and time history diagram of the Hamilton energy control for system (15). Figures 9(a) and 9(b) are the phase trajectories and time history diagram of the Hamilton energy control for system (15). The time history diagram for the system Hamilton energy control method and linear feedback control method is shown in Figure 10. It can be seen from Figure 10(a) that, in a certain period of time, the Hamilton energy controller makes the amplitude of the limit cycle smaller and smaller. Figure 10(b) is an enlarged view of Figure 10(a). Especially from Figure 10(b), we can know that the Hamilton energy control method makes the system close to the equilibrium state at $t = 27.53$. Above all, the Hamilton energy control system takes less time to reach the equilibrium state than the linear feedback control system. At the same time, controlled system (16) just still goes through the instability state.
Figure 7: The time history diagrams for system (15) with parameters as (a) $k = -0.07$, (b) $k = 0.04$, and (c) $k = 0.18$.

Figure 8: Phase trajectories (a) and time history diagram (b) for system (16), $a = 15$, $b = 0.01$, and $c = 1$.

Figure 9: Phase trajectories (a) and time history diagram (b) for system (15), $a = 15$, $b = 0.01$, $c = 1$, and $k = 0.02$. 
5. Conclusions

In this paper, a three-dimensional chaotic system with hidden attractors was designed firstly, and the dynamic behavior of the proposed chaotic system is described by quantitative analysis, such as the bifurcation diagram and largest Lyapunov exponent. Secondly, we calculated the Hamilton energy function by the Helmholtz theorem and applied the Hamiltonian energy control method to control the chaotic system with the cost of minimum energy. At last, numerical simulations were used to verify theory results. We also found that using Hamilton energy control method to chaotic system with hidden attractors was more effective about using less time to gain the same control effect through comparing with linear feedback control method.

Data Availability

The data used to support the findings of this study have been deposited in the article named “Calculation of Hamilton energy function of dynamical system by using Helmholtz theorem.”
