(Dated: April 3, 2018)

We consider the 3D Cahn-Hilliard equations coupled to, and driven by, the forced, incompressible 3D Navier-Stokes equations. The combination, known as the Cahn-Hilliard-Navier-Stokes (CHNS) equations, is used in statistical mechanics to model the motion of a binary fluid. The potential energy of the full binary system, designated as $E_{\infty}$, is shown to be regular in the 2D-case\textsuperscript{[31, 32]}, with an equivalent body of literature associated with the CH equations that distinguishes the fundamental equation for the statistical mechanics of binary mixtures, has been extensively studied in critical phenomena, phase transitions\textsuperscript{[8,12,13]}, nucleation\textsuperscript{[16]}, spinodal decomposition\textsuperscript{[17–20]}, and the late stages of phase separation\textsuperscript{[21, 22]}. If the two components of the binary mixture are fluids, the CH and NS equations must be coupled, where the resulting system of PDEs is usually referred to as Model H\textsuperscript{[9]} or the Cahn-Hilliard-Navier-Stokes (CHNS) equations.

The increasing growth of interest in the CHNS equations arises from the elegant way in which they allow us to follow the spatio-temporal evolution of the two components in the mixture \textit{and the interfaces between them}. These interfaces are diffuse, so we do not have to impose boundary conditions on the moving boundaries between two different fluids, as in other methods for the simulation of multi-phase flows\textsuperscript{[12,14]}. However, in addition to a velocity field $u$, we must also follow the scalar, order-parameter field $\phi$, which distinguishes the two phases in a binary-fluid mixture. Here, interfacial regions are characterized by large gradients in $\phi$. The CHNS equations have been used to model many binary-fluid systems that are of great current interest: examples include studies of (a) the Rayleigh-Taylor instability\textsuperscript{[23, 24]}; (b) turbulence-induced suppression of the phase separation of the two components of the binary fluid\textsuperscript{[11]}; (c) multifractal droplet dynamics in a turbulent, binary-fluid mixture\textsuperscript{[25]}; (d) the coalescence of droplets\textsuperscript{[26]}; and (e) lattice-Boltzmann treatments of multi-phase flows\textsuperscript{[19, 27]}. The system of Cahn-Hilliard-Navier-Stokes (CHNS) equations are written as follows\textsuperscript{[21, 28, 30]}:

\begin{equation}
(\partial_t + u \cdot \nabla) u = -\nabla p/\rho + \nu \nabla^2 u - \alpha \phi - (\phi \nabla \mu) - \alpha g + f,
\end{equation}

\begin{equation}
(\partial_t + u \cdot \nabla) \phi = \gamma \nabla^2 \mu,
\end{equation}

where $p$ is the pressure, and $\rho(=1)$ is the constant density, together with the incompressibility condition $\nabla \cdot u = 0$. In Eq. (1), $u = (u_x, u_y, u_z)$ is the fluid velocity and $\nu$ is the kinematic viscosity. In the 2D case $u_z = 0$ and $\alpha$, the air-drag-induced friction, should be included, but in 3D we set $\alpha = 0$. $\phi(x, t)$ is the order-parameter field at the point $x$ and time $t$ [with $\phi(x, t) > 0$ in the lighter phase and $\phi(x, t) < 0$ in the heavier phase]. The third term on the right-hand side of Eq. (1) couples $u$ to $\phi$ via the chemical potential $\mu(x, t)$, which is related to the free energy $F$ of the Cahn-Hilliard system as follows:

\begin{equation}
\mu = \delta F[\phi]/\delta \phi(x, t),
\end{equation}

\begin{equation}
F[\phi] = \Lambda \int_V \left[ \frac{\gamma}{2} |\nabla \phi|^2 + (\phi^2 - 1)^2/(4\xi^2) \right] dV,
\end{equation}

where $\Lambda$ is the energy density with which the two phases mix in the interfacial regime\textsuperscript{[24]}. $\xi$ sets the scale of the interface width, $\sigma = 2(2\pi)^2\Lambda/3\xi$ is the surface tension, $\gamma$ is the mobility\textsuperscript{[23]} of the binary-fluid mixture, $A = (\rho_2 - \rho_1)/(\rho_2 + \rho_1)$ is the Atwood number, and $g$ is the acceleration due to gravity. While solutions of the CHNS equations have been shown to be regular in the 2D-case\textsuperscript{[31, 32]}, with an equivalent body of literature associated with the CH equations...
alone (mainly 2D) (see, e.g., Ref. [34]) a critical issue for the 3D-CHNS system [11] - (4) revolves around the smoothness of the contours of ϕ packed together within the fluid interfaces. The regularity of the solutions of the 3D Navier-Stokes (NS) equations alone is in itself a major open problem [3]; a coupling of the CH and the NS equations poses additional severe difficulties. For instance, how do we know whether a slope discontinuity, such as a cusp, might develop in a finite time in arbitrarily large spatial derivatives of ϕ, thereby affecting the smoothness of these contours? Moreover, if such singularities do develop, how closely are they associated with the breakdown of regularity of the solutions of the 3D NS equations themselves? To answer such questions, we follow a strategy that is closely connected to an issue that once arose in studies of the incompressible 3D Euler equations (for a survey of the Euler literature see Refs. [32, 57]). Since the time of Leray [2, 5, 6] it has been known that the finiteness of \( \int_0^T \|u\|_\infty^2 \, dt \) or \( \int_0^T \frac{1}{2} \|\omega\|_2^2 \, dt \). In addition, other conditions exist involving the pressure \( \delta \). In contrast, prior to 1984, it was not known what variables control the regularity of solutions of the 3D Euler equations. Beale, Kato, and Majda [39] then proved that the time integral \( \int_0^T \|\omega\|_\infty \, dt \) is the key object: if this integral becomes infinite at a finite time \( T^* \), then solutions have lost regularity at \( T^* \) (i.e., blow-up occurs), but there exists a global solution if, for every \( T > 0 \), \( \int_0^T \|\omega\|_\infty \, dt < \infty \). This result is now generally referred to as the BKM theorem. Its practical value is that only one simple integral needs to be monitored numerically. It also discounts the possibility that very large spatial derivatives of \( u \) could develop a discontinuity if the integral is finite.

The main result of this paper is that we have shown that there exists a similar result for the 3D-CHNS system. It can be expressed very simply and takes its motivation from the energy \( E(t) \) of the full system, which can be written as

\[
E(t) = \int_V \left[ \frac{1}{2} \|\nabla \phi\|^2 + \frac{1}{4\xi^2} \left( \phi^2 - 1 \right)^2 + \frac{1}{2} \|u\|^2 \right] \, dV. \tag{5}
\]

Given that this can be viewed as a combination of squares of \( L^2 \)-norms, it suggests a corresponding \( L^\infty \) version, which we call the maximal energy \( \mathcal{E} \):

\[
\mathcal{E}(t) = \frac{1}{2} \|\nabla \phi\|_\infty^2 + \frac{1}{4\xi^2} \left( \|\phi\|^2 - 1 \right)^2 + \frac{1}{2} \|u\|_\infty^2. \tag{6}
\]

In Sec. III we prove a theorem which says that \( \int_0^{T^*} \mathcal{E}(\tau) \, d\tau \) is the key object that controls regularity of solutions of the 3D CHNS equations exactly in the same fashion as \( \int_0^{T^*} \|\omega\|_\infty \, d\tau \) does for the 3D Euler equations [32]. The proof of the theorem is technically complicated, so this is given in Appendix A. Our numerical calculations in that Section (Fig. 1 (left)) suggest that \( E_\infty \) is indeed finite.

In order to make a comparison with 3D Navier-Stokes results, we also calculate the time dependence of scaled \( L^m \)-norms of other fields, such as the fluid vorticity \( \omega \). The study of similar scaled norms has led to fruitful insights into the solutions of the 3D NS equations [12] and the 3D MHD equations [13]. We find that plots of all these norms, versus time \( t \), are ordered as a function of \( m \) (curves with different values of \( m \) do not cross); and, as \( m \to \infty \), these curves approach a limit curve that can be identified as the scaled \( L^\infty \) norm.

The remainder of this paper is organized as follows: In Sec. IIII we discuss the numerical methods that we use to study its solutions. Section III is devoted to the statement of our \( E_\infty \) theorem and associated numerical results together with plots of the \( L^m \) norms mentioned in the last paragraph. Section IV contains concluding remarks. In the Appendix we describe the details of the proof of the theorem.

II. NUMERICAL METHODS

We carry out direct numerical simulations (DNSs) of the 3D CHNS equations. For this we use a simulation domain that is a cubical box with sides of length 2\( \pi \) and periodic boundary conditions in all three directions. We use \( N^3 \) collocation points, a pseudo-spectral method with a 1/2-dealiasing rule, and a second-order Adams-Bashforth method for time marching. In our DNSs we use the following two types of forcing: (a) In the first type, we use the gravity-driven Rayleigh Taylor instability (RTI) of the interface of a heavy fluid that is placed initially on top of a light fluid; this instability is of great importance in inertial-confinement fusion [44, 45], astrophysical phenomena [28], and in turbulent mixing, especially in oceanography [16]. (b) In the second type, we have a forcing that yields a constant energy-injection rate [17]. In our RTI studies, there is a constant gravitational field in the \( \hat{z} \) direction; here we stop our DNS just before plumes of the heavy or light fluid wrap around the simulation domain in the \( \hat{z} \) direction because of the periodic boundary conditions. Most of the DNSs of such CHNS problems, e.g., CHNS studies of the RTI, have been motivated by experiments [46, 50]. To the best of our knowledge, no studies have investigated the growth of \( L^m \) norms of the quantities we have mentioned above. (For the RTI problem, some of these norms have been studied [51] by using the DNS results of Ref. [52] for the miscible, two-fluid, incompressible 3D NS equations.) It behooves us, therefore, to initiate such DNS investigations of \( L^m \) norms of fields in the 3D CHNS equations.

The last-but-one term in Eq. (1) is used in our DNSs of the RTI; in these studies we set the external force \( f = 0 \). We also carry out DNSs, with no gravity, but
TABLE I: The parameters for our DNS runs T1-T3. The number of collocation points is \( N \), \( A \), \( \nu \), \( D \), \( \sigma \), \( \text{Ch} \) and \( \text{Gr} \) for DNS runs T1-T3. We give the parameters for our DNS runs T1-T3 in Table I.

| \( N \) | \( A \) | \( \nu \) | \( D \) | \( \sigma \) | \( \text{Ch} \) | \( \text{Gr} \) | \( \text{Re}_\lambda \) |
|---|---|---|---|---|---|---|---|
| T1 | 256 | 0.5 | 0.00116 | 0.0015 | 0.23 | 0.011 | 1.2 \times 10^4 |
| T2 | 128 | 0 | 0.0116 | 0.0015 | 0.23 | 0.011 | 1.2 \times 10^3 |
| T3 | 512 | 0 | 0.00116 | 0.0015 | 0.23 | 0.011 | 1.2 \times 10^3 |

The finiteness, or otherwise, of \( E_{\infty}(t) \) is thus critical to the regularity of solutions. This needs to be tested numerically from different initial conditions. One way is to plot finite \( L^m \)-norms of the energy, namely,

\[
E_m(t) = \frac{1}{2} \Lambda \| \nabla \phi \|_m^2 + \frac{\Lambda}{4k^2} (\| \phi \|_m^2 - 1)^2 + \frac{1}{2} \| u \|_m^2, \tag{11}
\]

for increasing values of \( m \geq 1 \). We observe that \( E_m(t) \) converges as \( m \) increases: see Fig. 2 (top panels). This suggests that the integral criterion within Theorem 1 is indeed finite and thus 10 holds leading to the regularity of these solutions, at least for the DNSs we carry out.

### B. Temporal Evolution of \( D_m \)

The initial stages of the spatiotemporal development of the RTI in the 3D CHNS system is illustrated by the isosurface plots of the \( \phi \) field in Fig. 1 (the spatiotemporal development of this field is given in the Video RTI Atwood=5e-1 in the Supplemental Material [53]). In RTI flows, the potential energy that is stored in the initial density field is converted to kinetic energy, which initiates fluid-mixing and a cascade of energy from large to small length scales; this gives rise to filamentary structures with enhanced gradients in \( \phi \). The nonlinearity of the binary-fluid system is responsible for this energy cascade.

For both the 3D Navier-Stokes and 3D MHD equations, a method was introduced to estimate the degree of nonlinear depletion in the vortex stretching term(s) \[40-42\]. It involved the use of the following \( L^m \)-norms of the vorticity field \( \omega = \nabla \times u \) defined by \( (1 \leq m < \infty) \),

\[
\Omega_m(t) = \left( \int_V |\omega|^{2m} dV \right)^{1/2m}, \tag{12}
\]

and also the following scaled dimensionless counterparts of \( \Omega_m \)

\[
D_m(t) = \left( \frac{2}{\nu} \right) \Omega_m^{-\frac{1}{2}} \Omega_m^m, \quad m = \frac{2m}{4m - 3}, \tag{13}
\]

where \( \nu = L^{-2} \) is the box-size frequency of the periodic box. Although the \( \Omega_m \)'s must obey Hölder’s inequality

\[
\Omega_m \leq \Omega_{m+1}, \quad 1 \leq m < \infty, \tag{14}
\]

no such natural ordering is enforced upon the \( D_m \), because the \( \alpha_m \) decrease with \( m \) (see Eq. 13). We give the plots for \( D_m \)'s for the RTI case in Fig. 3(a) and for the constant-energy-injection scheme in Fig. 3(d).

It was shown in Ref. [42] that there are good reasons why \( D_m \) and \( D_1 \) are such that

\[
D_m \leq D_1 \omega_m(t), \tag{15}
\]
FIG. 1: (Color online) Isosurface plots of the \( \phi \)-field in the 3D CHNS equations illustrating the development of the RTI with large-wavelength perturbations in 3D (DNS run T1 in Table I), with 256\(^3\) collocation points, at times (a) \( t = 1 \), (b) \( t = 10 \), (c) \( t = 25 \), and (d) \( t = 36 \). The spatiotemporal development of this field is given in the Video RTL Atwood=5e-1 in YouTube.

with the additional relation that includes the time-dependent exponents \( \lambda_m \)

\[
A_m(t) = \frac{\lambda_m(t)(m - 1) + 1}{4m - 3}. \tag{16}
\]

It was observed numerically \[11\] that the maxima of the \( \lambda_m \) lay in the range 1.15 – 1.45. For purposes of comparison between those calculations and our RTI simulation, we plot \( A_m(t) \) versus \( t \), in Fig. 3(b), where

\[
A_m(t) = \ln D_m / \ln D_1. \tag{17}
\]

We observe that the \( A_m \) do not change significantly with \( t \) but that they depend on \( m \). We also give the plot of \( A_m(t) \) versus \( t \) for the case of constant-energy-injection in Fig. 3(e). As in DNSs of the 3D Navier-Stokes equation \[41\], we find, for the 3D CHNS system, that \( D_1 \) lies well above the other \( D_m \) (see Fig. 3(a) and Fig. 3(c)). We give the plots for \( \lambda_m(t) \) in Fig. 3(c) (for the RTI case).
We also compute the temporal evolution of the $L^{2m}$-norms of the gradients of $\phi$ by using the definition of the inverse length scale $\ell_m^{-1}$:

$$
\ell_m^{-2m} = \frac{\int_V |\nabla \phi|^{2m} dV}{\int_V |\phi|^{2m} dV}.
$$

Figures 2(a)-(d) show plots of $E_m$ and $\ell_m^{-1}$ versus time $t$ for different values of $m$. These are qualitatively similar to those for $D_m$ in so far as curves for different values of $m$ do not cross; they are ordered in $m$ such that $\ell_m^{-1} < \ell_{m+1}^{-1}$. Furthermore, both $\ell_m^{-1}$ and $E_m$ approach limiting curves as $m \to \infty$. (We mention in passing that errors increase, as $m$ increases. We present data for values of $m$ and in Fig. 3(f) (for the constant-energy-injection forcing scheme). In the 3D NS case, the $\lambda_m$ are related to the spectral exponents for the inertial-range, power-law form of the energy spectra [41]; the analogous relation for the 3D CHNS case is not straightforward because the power-law ranges in such spectra depend on several parameters in the CHNS equations (see, e.g., Ref. [25]).
for which we have reliable data). This clustering of the $E_m$ suggests convergence to a finite value of $E_\infty$.

IV. CONCLUSION

The regularity of solutions of the 3D Navier-Stokes (3DNS) equations presents formidable difficulties. It remains to this day one of the outstanding open problems in modern applied mathematics [4]. Coupling these 3DNS equations to the 3D Cahn-Hilliard equations creates a set of 3D CHNS PDEs that govern an incompressible binary fluid, but, in so doing, creates a system where the already formidable difficulties with the 3D NS system are amplified many times over. The elegant and powerful proofs of regularity by Abels [31] and Gal and Graselli [32] in the 2D case show how much harder the coupled 2D CHNS system is to deal with than the 2D Navier-Stokes equations alone.

The main challenges in the 3D system considered here lie in the behavior of not only arbitrarily large gradients of the velocity field $\mathbf{u}$ but also of arbitrarily large gradi-
...ents of \( \phi \), the order parameter. The \( E_\infty \) theorem, stated in Sec. 111 and proved in Appendix A, is a conditional-regularity criterion on periodic boundary conditions that is realistically computable. The motivation for this result lies in the BKM theorem for the 3D Euler equations. Constantin, Fefferman and Majda [33] have reduced the \( \| \omega \|_\infty \) within the BKM criterion to \( \| \omega \|_p \) for finite \( p \geq 2 \), but at the heavy price of introducing technically complicated, local constraints on the direction of vorticity, which are difficult to compute. Thus, the original form of the BKM theorem, with its single requirement of \( \| \omega \|_\infty \) being finite, remains the simplest regularity criterion to this day. Our \( E_\infty \) theorem is the equivalent result for the 3D CHNS system.

Our curves for \( E_m \) versus time in Fig. 2 (left) suggest convergence to \( E_\infty \), with increasing values of \( m \), thereby indicating that solutions remain regular for as long as our DNSs remain valid, even though more resolution would be desirable in the future to investigate the delicate issue of possible finite-time singularities in solutions of the 3D CHNS equations.

Appendix A: Proof of Theorem 11

In the following proof the coefficients in Eqs. (1)-(4) in the main paper are set to unity to avoid needless complication. First, we recall the definitions of \( H_n \) and \( P_n \) in Eq. (8). In addition to these we define

\[
X_n = H_n + P_{n+1}.
\]

The proof uses the method of BKM [39], which is by contradiction. The strategy is the following: suppose there exists an interval \([0, T^*] \) on which solutions are globally regular with the earliest loss of regularity at \( T^* \). Assume that \( \int_0^{T^*} E_\infty(\tau) \, d\tau < \infty \), and then show that a consequence of this is that \( X_n(T^*) < \infty \), which contradicts the statement that solutions first lose regularity at \( T^* \). This falsifies the assumption of the finiteness of the integral. We proceed in 3 steps.

Step 1: We begin with the time evolution of \( P_n \) (the dot above \( P_n \) denotes a time derivative):

\[
\frac{d}{dt} P_n = -P_{n+2} + P_{n+1} + \int_V (\nabla^n \phi) \nabla^n \Delta (\phi^3) \, dV - \int_V (\nabla^n \phi) \nabla^n (u \cdot \nabla \phi) \, dV; \tag{A2}
\]

and then we estimate the third term on the right as

\[
\left| \int_V (\nabla^n \phi) \nabla^n \Delta (\phi^3) \, dV \right| \leq \| \nabla^n \phi \|_2 \sum_{i,j=0}^{n+2} C_{i,j}^n \| \nabla^i \phi \|_p \| \nabla^j \phi \|_q \| \nabla^{n+2-i-j} \phi \|_r, \tag{A3}
\]

where \( 1/p + 1/q + 1/r = 1/2 \). Now we use a sequence of Gagliardo-Nirenberg inequalities

\[
\begin{align*}
\| \nabla^i \phi \|_p &\leq c_{n,i} \| \nabla^{n+2-i} \phi \|_\infty \| \phi \|^{1-a_1}_\infty, \\
\| \nabla^j \phi \|_q &\leq c_{n,j} \| \nabla^{n+2-j} \phi \|_\infty \| \phi \|^{1-a_2}_\infty, \\
\| \nabla^n \phi \|_r &\leq c_{n,i,j} \| \nabla^{n+2-i-j} \phi \|_2 \| \phi \|^{1-a_3}_\infty,
\end{align*}
\]

where, in \( d \) dimensions,

\[
\begin{align*}
\frac{1}{p} &= \frac{i}{d} + a_1 \left( \frac{1}{2} - \frac{n+2}{d} \right), \\
\frac{1}{q} &= \frac{j}{d} + a_2 \left( \frac{1}{2} - \frac{n+2}{d} \right), \\
\frac{1}{r} &= \frac{n+2-i-j}{d} + a_3 \left( \frac{1}{2} - \frac{n+2}{d} \right).
\end{align*}
\]

Acknowledgments

Appendix A: Proof of Theorem 11

In the following proof the coefficients in Eqs. (1)-(4) in the main paper are set to unity to avoid needless complication. First, we recall the definitions of \( H_n \) and \( P_n \) in Eq. (8). In addition to these we define

\[
X_n = H_n + P_{n+1}.
\]

The proof uses the method of BKM [39], which is by contradiction. The strategy is the following: suppose there exists an interval \([0, T^*] \) on which solutions are globally regular with the earliest loss of regularity at \( T^* \). Assume that \( \int_0^{T^*} E_\infty(\tau) \, d\tau < \infty \), and then show that a consequence of this is that \( X_n(T^*) < \infty \), which contradicts the statement that solutions first lose regularity at \( T^* \). This falsifies the assumption of the finiteness of the integral. We proceed in 3 steps.

Step 1: We begin with the time evolution of \( P_n \) (the dot above \( P_n \) denotes a time derivative):

\[
\frac{d}{dt} P_n = -P_{n+2} + P_{n+1} + \int_V (\nabla^n \phi) \nabla^n \Delta (\phi^3) \, dV - \int_V (\nabla^n \phi) \nabla^n (u \cdot \nabla \phi) \, dV; \tag{A2}
\]

and then we estimate the third term on the right as

\[
\left| \int_V (\nabla^n \phi) \nabla^n \Delta (\phi^3) \, dV \right| \leq \| \nabla^n \phi \|_2 \sum_{i,j=0}^{n+2} C_{i,j}^n \| \nabla^i \phi \|_p \| \nabla^j \phi \|_q \| \nabla^{n+2-i-j} \phi \|_r, \tag{A3}
\]

where \( 1/p + 1/q + 1/r = 1/2 \). Now we use a sequence of Gagliardo-Nirenberg inequalities

\[
\begin{align*}
\| \nabla^i \phi \|_p &\leq c_{n,i} \| \nabla^{n+2-i} \phi \|_\infty \| \phi \|^{1-a_1}_\infty, \\
\| \nabla^j \phi \|_q &\leq c_{n,j} \| \nabla^{n+2-j} \phi \|_\infty \| \phi \|^{1-a_2}_\infty, \\
\| \nabla^n \phi \|_r &\leq c_{n,i,j} \| \nabla^{n+2-i-j} \phi \|_2 \| \phi \|^{1-a_3}_\infty,
\end{align*}
\]

where, in \( d \) dimensions,

\[
\begin{align*}
\frac{1}{p} &= \frac{i}{d} + a_1 \left( \frac{1}{2} - \frac{n+2}{d} \right), \\
\frac{1}{q} &= \frac{j}{d} + a_2 \left( \frac{1}{2} - \frac{n+2}{d} \right), \\
\frac{1}{r} &= \frac{n+2-i-j}{d} + a_3 \left( \frac{1}{2} - \frac{n+2}{d} \right).
\end{align*}
\]
By summing these and using $1/p + 1/q + 1/r = 1/2$, it is seen that $a_1 + a_2 + a_3 = 1$. Thus, we have

$$
\int_V (\nabla^n \phi) \nabla^{n+2}(\phi^3) \, dV \leq c_n \|\nabla^n \phi\|_2 \|\nabla^{n+2} \phi\|_2 \phi_\infty^2 \leq \frac{4}{3} P_{n+2} + c_n P_n \|\phi\|_4^4 ,
$$

(A6)

and so Eq. (A2) becomes (here and henceforth coefficients such as $c_n$ are multiplicative constants),

$$
\frac{4}{3} \dot{P}_n = - \frac{4}{3} P_{n+2} + P_{n+1} + c_n \|\phi\|_4^4 P_n + \int_V (\nabla^n \phi)(\nabla^n (\mathbf{u} \cdot \nabla \phi)) \, dV .
$$

(A7)

Estimating the last term in Eq. (A7) we have

$$
\left| \int_V (\nabla^n \phi) \nabla^n (\mathbf{u} \cdot \nabla \phi) \, dV \right| = \left| - \int_V (\nabla^{n+1} \phi) \nabla^{n-1} (\mathbf{u} \cdot \nabla \phi) \, dV \right|
\leq \|\nabla^{n+1} \phi\|_2 \sum_{i=0}^{n-1} C_i^n \|\nabla^i \mathbf{u}\|_p \|\nabla^{n-1-i}(\nabla \phi)\|_q ,
$$

(A8)

where $1/p + 1/q = 1/2$. Now we use two Gagliardo-Nirenberg inequalities in $d$ dimensions to obtain

$$
\|\nabla^i \mathbf{u}\|_p \leq c \|\nabla^{n-1} \mathbf{u}\|_2 \|\nabla \phi\|_\infty^{1-a} ,
$$

(A9)

$$
\|\nabla^{n-1-i}(\nabla \phi)\|_q \leq c \|\nabla^{n-1}(\nabla \phi)\|_2 \|\nabla \phi\|_\infty^{1-b} .
$$

(A10)

Equations (A9) and (A10) follow from

$$
\frac{1}{p} = \frac{i}{d} + a \left( \frac{1}{2} - \frac{n - 1}{d} \right) ,
$$

(A11)

$$
\frac{1}{q} = \frac{n - 1 - i}{d} + b \left( \frac{1}{2} - \frac{n - 1}{d} \right) .
$$

(A12)

Because $1/p + 1/q = 1/2$ then $a + b = 1$. Thus Eq. (A3) turns into

$$
\left| \int_V (\nabla^n \phi) \nabla^n (\mathbf{u} \cdot \nabla \phi) \, dV \right| \leq c_n P_{n+1}^{1/2} H_{n-1}^{1/2} P_n \|\mathbf{u}\|_2^{1-a} \|\nabla \phi\|_\infty^{1-b}
\leq P_{n+1}^{1/2} \left[ c_n H_{n-1} \|\nabla \phi\|_\infty^2 \right]^{1/2} \left[ P_n \|\mathbf{u}\|_2^2 \right]^{b/2}
\leq \frac{4}{3} P_{n+1} + \frac{4}{3} a c_n H_{n-1} \|\nabla \phi\|_\infty^2 + \frac{4}{3} b P_n \|\mathbf{u}\|_2^2 ,
$$

(A13)

and Eq. (A7) becomes

$$
\frac{4}{3} \dot{H}_n = - \frac{4}{3} P_{n+2} + \frac{4}{3} P_{n+1} + c_n, \left( \frac{4}{3} \|\phi\|_\infty^4 + \|\mathbf{u}\|_\infty^2 \right) P_n + c_n H_{n-1} \|\nabla \phi\|_\infty^2 .
$$

(A14)

Step 2: Now we look at $H_n$ defined in Eq. (8) using Eq. (A15) with $f = -\hat{\xi} \phi$. The easiest way is to use the 3D NS equation in the vorticity form as in Doering and Gibbon [4] to obtain the $\|\mathbf{u}\|_\infty^2$-term in Eq. (A10), where gradient terms have been absorbed into the pressure term, which disappears under the curl-operation:

$$
(\partial_t + \mathbf{u} \cdot \nabla) \omega = \Delta \omega + \omega \cdot \nabla \mathbf{u} + \nabla \phi \times \nabla \Delta \phi - \nabla \hat{\xi} \phi .
$$

(A15)

Therefore,

$$
\frac{4}{3} \dot{H}_n \leq - \frac{4}{3} H_{n+1} + c_n \|\mathbf{u}\|_\infty^2 H_n + \int_V (\nabla^{n-1} \omega) \left[ \nabla^{n-1} (\nabla \phi \times \nabla \Delta \phi) \right] \, dV
\leq \left| \int_V (\nabla^{n-1} \omega) \left[ \nabla^{n-1} (\nabla \phi \times \nabla \Delta \phi) \right] \, dV \right|
$$

(A16)

Beginning with the third term on the right-hand side of Eq. (A10), we obtain

$$
\left| \int_V (\nabla^{n-1} \omega) \nabla^{n-1} (\nabla \phi \times \nabla \Delta \phi) \, dV \right| \leq \|\nabla^{n-1} \omega\|_2 \sum_{i=0}^{n-1} C_i^n \|\nabla^i (\nabla \phi)\|_r \|\nabla^{n-1-i}(\nabla \phi)\|_s .
$$

(A17)
where $1/r + 1/s = 1/2$ and where

$$
\frac{1}{r} = \frac{i}{d} + a \left( \frac{1}{2} - \frac{n+1}{d} \right) \quad (A20)
$$

$$
\frac{1}{s} = \frac{n+1-i}{d} + b \left( \frac{1}{2} - \frac{n+1}{d} \right) \quad (A21)
$$

we find that $a + b = 1$. This yields

$$
\left| \int_V (\nabla^{-1} \omega) \nabla^{n-1} (\nabla \times \Delta \phi) \, dV \right| \leq c_n H_n^{1/2} P_{n+2}^{1/2} \| \nabla \phi \|_\infty
$$

$$
\leq P_{n+2} + \frac{4}{2} c_n H_n \| \nabla \phi \|_\infty^2 . \quad (A22)
$$

The last term on the right-hand side of Eq. (A16) is easily handled. Altogether we find

$$
\frac{d}{dt} H_n \leq -\frac{4}{2} H_{n+1} + P_{n+2} + c_{n,3} \left( \| u \|_\infty^2 + \| \nabla \phi \|_\infty^2 \right) H_n + \frac{4}{2} c_n H_n \| \nabla \phi \|_\infty^2 . \quad (A23)
$$

**Step 3:** Finally, by noting that $X_n = P_{n+1} + H_n$, we use Eq. (A6) with $n \to n + 1$ to obtain

$$
\frac{d}{dt} X_n \leq -\frac{4}{2} P_{n+3} + \frac{4}{2} P_{n+2} + c_{n,1} \left( \frac{4}{2} \| \phi \|_4^4 + \| u \|_\infty^2 \right) P_{n+1} + c_{n,2} H_n \| \nabla \phi \|_\infty^2
$$

$$
-\frac{4}{2} H_{n+1} + P_{n+2} + c_{n,3} \left( \| u \|_\infty^2 + \| \nabla \phi \|_\infty^2 \right) H_n + \frac{4}{2} c_n H_n + \frac{4}{2} P_n
$$

$$
\leq -\frac{4}{2} P_{n+3} - \frac{4}{2} H_{n+1} + \frac{4}{2} P_{n+2} + c_{n,4} \left( \frac{4}{2} \| \phi \|_\infty^4 + \| u \|_\infty^2 + \| \nabla \phi \|_\infty^2 \right) X_n + \frac{4}{2} H_n + \frac{4}{2} P_n . \quad (A24)
$$

By using $P_{n+2} \leq P_{n+3}^{1/2} P_{n+1}^{1/2} \leq (\varepsilon/2) P_{n+3} + (1/2 \varepsilon) P_{n+1}$, with $\varepsilon$ chosen as $\varepsilon = \frac{1}{4}$, we have (with $P_n \leq P_{n+1}$)

$$
\frac{d}{dt} X_n \leq -\frac{4}{2} P_{n+3} - \frac{4}{2} H_{n+1} + c_{n,4} \left( \| \nabla \phi \|_\infty^2 + \frac{4}{2} \| \phi \|_\infty^4 + \| u \|_\infty^2 + \frac{4}{2} \right) X_n . \quad (A25)
$$

We note that $\phi$ is a mean-zero function on a unit periodic domain, so $\| \phi \|_\infty \leq \| \nabla \phi \|_\infty$. Then we can write

$$
c_{n,4} \left( \| \nabla \phi \|_\infty^2 + \frac{4}{2} \| \phi \|_\infty^4 + \| u \|_\infty^2 + \frac{4}{2} \right) = c_{n,4} \left( \| \nabla \phi \|_\infty^2 + \frac{4}{2} \left( \| \phi \|_\infty^2 - 1 \right)^2 + \| u \|_\infty^2 + \| \phi \|_\infty^2 \right)
$$

$$
\leq 2 c_{n,4} \left( \| \nabla \phi \|_\infty^2 + \frac{4}{2} \left( \| \phi \|_\infty^2 - 1 \right)^2 + \| u \|_\infty^2 \right) . \quad (A26)
$$

By dropping the negative terms, Eq. (A25) turns into

$$
\frac{d}{dt} X_n \leq c_{n,4} E_\infty X_n , \quad (A27)
$$

where $E_\infty$ is defined in Eq. (6). By integrating over $[0, T^*]$, we obtain

$$
X_n(T^*) \leq c_{n,5} X_n(0) \exp \int_0^{T^*} E_\infty(\tau) \, d\tau . \quad (A28)
$$

The assumption that the time integral is finite implies that $X_n(T^*) < \infty$, which contradicts the statement in the Theorem that solutions first lose regularity at $T^*$.
