Report

Regulation of NGF Signaling by an Axonal Untranslated mRNA

Highlights

- Tp53inp2 is the most abundant mRNA in SN axons but is not translated

- Tp53inp2 transcript interacts with the TrkA receptor to regulate NGF signaling

- In SNs, Tp53inp2 functions independently of its protein-coding capacity

- Tp53inp2 transcript is essential for axon growth and target innervation in vivo

In Brief

Crerar et al. report that Tp53inp2, an mRNA transcript abundantly localized in axons of sympathetic neurons, interacts with the NGF receptor TrkA. The Tp53inp2 transcript is not translated but acts in a coding-independent manner to regulate axon growth and neuronal survival in vivo.
Regulation of NGF Signaling by an Axonal Untranslated mRNA

SUMMARY

Neurons are extraordinarily large and highly polarized cells that require rapid and efficient communication between cell bodies and axons over long distances. In peripheral neurons, transcripts are transported along axons to growth cones, where they are rapidly translated in response to extrinsic signals. While studying Tp53inp2, a transcript highly expressed and enriched in sympathetic neuron axons, we unexpectedly discovered that Tp53inp2 is not translated. Instead, the transcript supports axon growth in a coding-independent manner. Increasing evidence indicates that mRNAs may function independently of their coding capacity; for example, acting as a scaffold for functionally related proteins. The Tp53inp2 transcript interacts with the nerve growth factor (NGF) receptor TrkA, regulating TrkA endocytosis and signaling. Deletion of Tp53inp2 inhibits axon growth in vivo, and the defects are rescued by a non-translatable form of the transcript. Tp53inp2 is an atypical mRNA that regulates axon growth by enhancing NGF-TrkA signaling in a translation-independent manner.

INTRODUCTION

Neurons are highly morphologically complex cells that require the expression of a large number of genes encoding proteins that support growth, branching and synaptic functions in dendrites, and growth cone migration, extension, and regeneration in axons (Andreassi et al., 2018; Terenzio et al., 2017). Neuronal cells rely on asymmetric localization of mRNAs to compartmentalize gene expression, a mechanism shared with most eukaryotic cells (Martin and Ephrussi, 2009). Transcripts are transported to dendrites and axons, where they can be rapidly translated in response to extrinsic signals, such as synaptic activity, neurotrophic factors, guidance cues, and injury (Andreassi et al., 2010; Cajigas et al., 2012; Gumy et al., 2011; Riccio, 2018; Sambandan et al., 2017; Terenzio et al., 2018). Genome-wide screens performed on RNA isolated from either dendrites or axons revealed that thousands of transcripts are asymmetrically localized in neurons (Andreassi et al., 2010, 2019; Cajigas et al., 2012; Gumy et al., 2011; Shigeoka et al., 2016). However, how peripherally localized transcripts influence axon growth and whether they may function independently of their translational capacity remains largely unknown.

Here we show that Tp53inp2, one of the most abundant and enriched mRNA transcripts in axons, is not translated in sympathetic neurons and regulates axon growth in a coding-independent manner. The unusually long 3′ UTR of Tp53inp2 maintains the transcript in a translationally repressed state, possibly conferring to the transcript unique, neuron-specific roles. Importantly, we demonstrate that Tp53inp2 interacts with the nerve growth factor (NGF) receptor TrkA, promoting receptor trafficking and intracellular signaling. Analysis of transgenic mice lacking Tp53inp2 demonstrated that the gene is required for axon growth and sympathetic target innervation. Noticeably, the defects were rescued by a translation-deficient Tp53inp2 transcript, indicating that, at least in sympathetic neurons, Tp53inp2 functions independently of translation. Thus, our study reveals the essential role of the Tp53inp2 transcript in regulating sympathetic neuron growth and innervation and represents the first evidence of an axonal mRNA capable of directly modulating NGF-TrkA signaling.

RESULTS AND DISCUSSION

The Tp53inp2 Transcript Is Highly Expressed, but Not Translated, in Sympathetic Neuron Axons

Eukaryotic mRNAs include a coding sequence (CDS) encoding the protein and flanking UTRs of variable length, called 5′ and 3′ UTRs, that harbor regulatory elements that determine transcript localization, stability, and translation (Andreassi and Riccio, 2009; Lianoglou et al., 2013). To obtain a comprehensive characterization of the 3′ UTR transcript isoforms expressed in sympathetic neuron axons, we performed 3′ end RNA sequencing (RNA-seq) on mRNA isolated from either axons or cell bodies of rat sympathetic neurons cultured in compartmentalized chambers (Andreassi et al., 2019). In this model system, NGF is added only to the lateral axonal compartment, creating...
Figure 1. Tp53inp2 Translation Is Repressed in Sympathetic Neurons

(B) Western blot of lysates of HeLa cells treated with cycloheximide (CHX) for the indicated time (n = 3).

(C) qRT-PCR of Tp53inp2 and β-actin in polysomal fractions from sympathetic neurons lysates; paired two-tailed t test (n = 3, **p < 0.01).

(D–F) Pseudo-selected reaction monitoring traces for the detection of a Tp53inp2 tryptic peptide in cultured sympathetic neuron axon (E) or cell body (F) samples and in an immunoprecipitated myc-Tp53inp2 control (D). The four traces represent the 4 most abundant fragments of the Tp53inp2 peptide ALHHAAAPMoxP AR. Arrows indicate where at least three transitions are detected at the same retention time, indicating peptide presence. Top value on trace, retention value; bottom value, mass to charge ratio (m/z).

(legend continued on next page)
experimental conditions that closely resemble the release of neurotrophins from target tissues (Kuruvilla et al., 2000; Riccio et al., 1997), mRNA was subjected to two rounds of linear poly(A) amplification before sequencing to enrich for 3’ UTRs (Andreas et al., 2019; Andreas et al., 2010). Tp53inp2 was the most abundant transcript in axons, accounting for almost one-third of the reads (Figures S1A and S1B). The transcript is unusual in that the 3’ UTR is over 3,000 nt long (3,121 nt), accounting for nearly 80% of the transcript length, whereas the open reading frame (ORF) is 666 nt long, encoding a small protein of predicted low complexity. Although the Tp53inp2 protein has been implicated in the regulation of autophagy in skeletal muscle fibers and other mammalian cell lines (Nowak et al., 2009; Sala et al., 2014), extensive attempts to detect the endogenous Tp53inp2 protein in PC12 cells and sympathetic neurons using either homemade, commercial, or previously published antibodies were unsuccessful. Western blotting of PC12 cells transfected with a vector expressing the CDS of Tp53inp2 showed that, under these conditions, the transcript was translated and easily detected (Figure 1A; Figures S1C and S1D). Co-transfection with a small interfering RNA (siRNA) that efficiently inhibited Tp53inp2 expression completely abolished the signal (Figure 1A), indicating the specificity of the antibodies. Importantly, we tested several cell types and confirmed that endogenous Tp53inp2 was expressed in HeLa cells (Xu et al., 2016) and that the protein was stable, with a half-life of at least 4 h (Figure 1B; Figure S1E).

To further investigate whether Tp53inp2 mRNA was translated in sympathetic neurons, we performed polysome fractionation (Johannes and Sarnow, 1996). Although not devoid of limitations, the technique allows an accurate prediction of transcript translation rates. qRT-PCR of the Tp53inp2 transcript associated with either polyribosomes or monosomes revealed that, in sympathetic neurons, a large fraction of Tp53inp2 mRNA co-sedimented with the monosomal fraction, whereas the efficiently translated transcript β-actin was mostly associated with polysomes (Figure 1C; Figure S1F). Although monosomes in yeast can translate transcripts containing an ORF of up to 600 nt (Heyer and Moore, 2016), we further investigated, using mass spectrometry, whether Tp53inp2 protein was expressed in sympathetic neurons. Three proteotypic peptides identified by a data-dependent analysis of immunoprecipitated Tp53inp2 were selected for high-sensitivity detection in targeted mode (Table S1). Targeted mass spectrometry performed either on severed axons or cell bodies of sympathetic ganglia explants (superior cervical ganglia [SCG]) confirmed that Tp53inp2 peptides were not present in axons (Figures 1D–1F; Figure S1G). Very small signals corresponding to ALHAAAPmoxPAR and HQGSIYPCQR fragment ions were detected at the limit of the signal-to-noise ratio only in cell bodies (Figure 1F; Figure S1G). It should be noted however, that SCG explants contain few non-neuronal cells that may account for the Tp53inp2 peptides detected in the cell body samples. Thus, although we cannot exclude the possibility that the Tp53inp2 transcript is translated at extremely low levels in cell bodies of sympathetic neurons, Tp53inp2 protein was undetectable in axons using three distinct sensitive technical approaches.

The unexpected finding that, despite its abundance, Tp53inp2 mRNA was not synthesized into a protein prompted us to investigate the mechanisms that maintain the transcript in a translationally silent state in sympathetic neurons. Because vectors expressing only the coding region of Tp53inp2 were translated (Figure 1A; Figures S1C and S1D), we reasoned that the Tp53inp2 3’ UTR may harbor regulatory elements that inhibit translation. To this end, we generated expression vectors carrying the 5’ UTR of Tp53inp2 upstream of the coding region of GFP and followed by either the full-length (~3,100 nt) or truncated forms (~2,200 nt and ~1,200 nt, respectively) of the Tp53inp2 3’ UTR. Although there were some differences in the expression levels of one vector (Figure S1), when relative mRNA expression was taken into account, shortening of the 3’ UTR correlated with substantial relief of translational inhibition (Figure 1G; Figure S1H). A possible implication of these results is that cells expressing Tp53inp2 protein also express a Tp53inp2 transcript harboring a shorter 3’ UTR. Indeed, qRT-PCR performed on RNA isolated from either sympathetic neurons or HeLa cells revealed that an isoform bearing a shorter 3’ UTR was predominantly expressed in HeLa cells (Figure S1J). These findings indicate that elements contained within the longer 3’ UTR may be responsible for maintaining the transcript translationally silent in sympathetic neurons.

**The Tp53inp2 Transcript Interacts with the TrkA Receptor to Mediate NGF Signaling**

Recent studies have shown that 3’ UTRs may have a more flexible role in regulating gene expression than previously thought (Andreas et al., 2018; Mayr, 2017). In hippocampal neurons, for example, an E3 ubiquitin ligase isoform expressing a short 3’ UTR (Ube3a1) inhibits dendritogenesis in a coding-independent manner by competing with endogenous Ube3a for miR-134 binding (Valuy et al., 2015). Moreover, in cancer cell lines, the long 3’ UTR of the CD47 transcript acts as a scaffold for RNA binding proteins (RBPs) and determines the translational control of the CD47 protein to the plasma membrane (Berkovits and Mayr, 2015).

In axons, NGF binds to its cognate receptor TrkA and, following receptor dimerization and autophosphorylation, ligand-receptor complexes are internalized within endosomes and retrogradely transported to the cell bodies (Harrington and Ginty, 2013; Yamashita and Kuruvilla, 2016). Signaling endosomes regulate axon growth and are transported long-distance to somato-dendritic compartments to modulate synapse assembly and activate transcription (Leigh et al., 2017; Scott-Solomon and Kuruvilla, 2018). Given the lack of translation, we reasoned that in sympathetic neurons, the Tp53inp2 transcript could influence NGF signaling in a coding-independent manner. We first investigated

(G) Left: western blot of PC12 cells co-transfected with GFP fusion constructs containing Tp53inp2 3’ UTR 3.1, 2.2, or 1.2 kb and an mCherry control vector. Right: densitometry of GFP protein levels was normalized by mCherry levels and then further normalized by levels of GFP mRNA. Values are expressed as percentage of the mean GFP protein amount of the 1.2-kb construct. Ordinary one-way ANOVA, Tukey’s multiple comparisons test (n = 5, *p < 0.05, **p < 0.001). Data are presented as average ± SEM. See also Figure S1.
(legend on next page)
whether Tp53inp2 transcripts interacted with the TrkA receptor in axons by performing RNA immunoprecipitation (RIP) on sympathetic neurons. Remarkably, the pan-Trk antibody immunoprecipitated the Tp53inp2 transcript, and the interaction was greatly increased in response to NGF stimulation (Figure 2A; Figure S2A). The cognate receptor TrkB also interacted with Tp53inp2 in mouse cortical neurons (Figure 2B), whereas, in sympathetic neurons, the highly abundant axonal transcript IMPA1-L was not immunoprecipitated (Andreassi et al., 2010; Figure S2A). Both transcripts were immunoprecipitated by the neuron-specific RBP HuD (Figures S2B and S2C), and endogenous HuD and TrkA co-immunoprecipitated in sympathetic neurons (Figure S2D), suggesting that HuD may mediate TrkA binding to the Tp53inp2 transcript. As a control, we performed RIP of Tp53inp2 with another transmembrane protein, NCAM, and found no significant interaction (Figures S2E and S2F).

Next, we asked whether the Tp53inp2 transcript influences NGF signaling in sympathetic neurons. To this end, we generated transgenic mice carrying a floxed allele of Tp53inp2 in mouse cortical neurons (where exons 2 and 3 are flanked by loxP sites (Tp53inp2fl/fl mice) (Figure S2G). To assess the effects of Tp53inp2 loss on NGF signaling in axons, SCG explants isolated from Tp53inp2fl/fl mice on postnatal day 0.5 (P0.5) were infected with either an adenoviral vector expressing the Cre recombinase to acutely delete Tp53inp2 (Figure S2H) or a LacZ virus as a control. Cell bodies were mechanically severed, and the isolated axons were stimulated with NGF. Axon protein lysate was either immunoblotted for the canonical signaling effectors Erk1-2 and Akt or subjected to immunoprecipitation with a phospho-tyrosine antibody, and the pellet was immunoblotted using antibodies for TrkA. As expected, NGF stimulation increased pTrkA, pAkt, and pErk1-2 levels in axons under control conditions, whereas NGF-mediated phosphorylation of TrkA and downstream effectors was inhibited in axons lacking Tp53inp2 (Figures 2C and 2D), indicating that Tp53inp2 interaction with TrkA receptors mediates TrkA signaling in axons. Moreover, immunofluorescence analysis showed that Tp53inp2 depletion significantly decreased the retrograde appearance of phosphorylated TrkA receptors in cell bodies of cultured sympathetic neurons lacking Tp53inp2 (Figure 2E).

A key event that mediates NGF-Trk signaling is the ligand-induced endocytosis of TrkA receptors. The inhibition of local and retrograde NGF signaling in Tp53inp2-deficient neurons prompted us to investigate whether Tp53inp2 could influence TrkA internalization. To this end, we performed a live-cell antibody-feeding assay (Yamasita et al., 2017) on Tp53inp2fl/fl sympathetic neurons co-infected with adenoviruses expressing either LacZ or Cre and FLAG-TrkA. Robust receptor internalization was observed in both cell bodies and axons of control neurons in response to NGF stimulation (Figures 2F and 2G). In contrast, internalization was markedly attenuated in neurons lacking Tp53inp2. Similar results were obtained when internalization of endogenous TrkA receptors was probed using a cell surface biotinylation assay (Houtz et al., 2016). NGF-induced TrkA internalization was significantly reduced in neurons lacking Tp53inp2 compared with control conditions (Figure S3A). Loss of Tp53inp2 had no effect on basal levels of surface TrkA (Figures S3B and S3C) or on total TrkA protein expression in sympathetic neurons (Figure S3D). Together, these results indicate that Tp53inp2 regulates NGF-dependent TrkA internalization.

**Tp53inp2 is a Translationally Repressed mRNA that Affects Cell Survival and Axon Growth**

The findings that the Tp53inp2 transcript interacts with the TrkA receptor and regulates NGF signaling in sympathetic neurons prompted us to investigate whether it affected NGF-dependent axon growth and cell survival. Tp53inp2fl/fl sympathetic neurons were grown in compartmentalized chambers with NGF added only to distal axons and infected with either Cre or LacZ adenoviruses (Figure S3E). Neurons expressing LacZ showed robust growth in the presence of NGF (Figures 3A and S3B). In contrast, NGF-mediated growth was remarkably stunted in neurons lacking Tp53inp2 (Figures 3A and S3B). To determine whether the...
Tp53inp2 transcript rescued the growth defects induced by Tp53inp2 loss, adenoviral vectors expressing either full-length wild-type (WT) Tp53inp2 or a form bearing mutations of all putative translational start sites within the 3′ UTR (ATGNull) were generated (Figure S3F). Western blotting and qRT-PCR confirmed that the WT and ATGNull Tp53inp2 transcripts were not translated despite being transcribed efficiently in PC12 cells (Figures S3G, S4A, and S4B). When Tp53inp2-deficient neurons were infected with either one of the two adenoviral vectors, we observed that the WT and ATGNull Tp53inp2 were equally efficient in rescuing axon growth defects induced by the loss of Tp53inp2 (Figures 3C and 3D). Together, these findings indicate that Tp53inp2 translation is not required for promoting sympathetic neuron axon growth and support the hypothesis that it may function outside of its coding capacity.

Next, we asked whether Tp53inp2 loss would compromise the ability of axonally applied NGF to retrogradely support neuronal survival. The survival of Tp53inp2 WT neurons was studied in the absence or presence of NGF on distal axons. When NGF was withdrawn, 80% of neurons in both LacZ- and Cre-infected neurons underwent apoptotic cell death (Figure 3E). NGF added to the distal axons was sufficient to promote survival of the majority of LacZ-infected neurons, whereas neurons lacking Tp53inp2 continued to exhibit significant levels of apoptosis (Figure 3E; Figure S4C). In line with evidence showing that NGF applied directly to cell bodies promotes neuronal survival by an endocytosis-independent mechanism (Riccio et al., 1997; Ye et al., 2003), we found that, under these conditions, loss of Tp53inp2 did not increase apoptosis (Figure 3E; Figure S4C). Thus, Tp53inp2 supports neuronal survival by regulating endocytosis and retrograde trafficking of NGF–TrkA receptor complexes.

**The Tp53inp2 Transcript Is Necessary for Sympathetic Neuron Target Innervation**

Next, we investigated whether the loss of Tp53inp2 affected sympathetic neuron survival and growth in vivo. First, in situ hybridization confirmed that Tp53inp2 transcript is expressed in sympathetic neuron ganglia at high levels from embryonic day 14.5 (E14.5) until early postnatal stages, a time when they are highly dependent on NGF for cell survival and axon growth (Figure 4A). Fluorescence in situ hybridization (FISH) of the 3′ UTR of the Tp53inp2 transcript showed punctate staining in both axons and cell bodies of sympathetic neurons (Figure 4B). The FISH signal was lost when the assay was performed on Tp53inp2 WT neurons infected with an adenoviral vector expressing the Cre recombinase, confirming the specificity of the FISH signal.

To generate mice lacking Tp53inp2 in sympathetic neurons, Tp53inp2 WT/WT animals were crossed with transgenic mice expressing the Cre recombinase under the control of the tyrosine hydroxylase promoter (Th-Cre;Tp53inp2 WT/WT mice; Gong et al., 2007; Figure S2G), which resulted in efficient deletion (Figure S4D). Analyses of the SCGs revealed normal numbers of sympathetic neurons in Th-Cre;Tp53inp2 WT/WT mice at E16.5 but significant cell loss at birth (P0.5) and 3 weeks after birth (P21) compared with control littermates (Figure 4C). Despite the absence of neuronal loss at E16.5, sympathetic innervation of the heart was decreased in the mutant embryos, with a significant reduction in both density of innervation and axonal branching in Th-Cre;Tp53inp2 WT/WT embryos compared with control littermates (Figures 4D and 4E). Taken together, these findings indicate that Tp53inp2 is required for the development of sympathetic neurons when they are most dependent on NGF for cell survival and axon growth.

NGF is secreted by the target tissues and acts locally in axons to support growth. The signal generated by the interaction of NGF with TrkA receptors is also retrogradely transported to the cell bodies, where it initiates nuclear events necessary for cell survival and axon growth (Ascano et al., 2012; Harrington and Ginty, 2013). We observed that the defects of target innervation preceded neuronal loss, suggesting that lack of Tp53inp2 primarily affects axon growth in vivo. Thus, in mice lacking Tp53inp2, neuronal loss was likely due to the axons failing to reach the target tissues and gain access to adequate levels of NGF. We cannot exclude, however, that impaired retrograde NGF signaling from distal axons to the cell bodies may also play a role.

**Crosstalk between NGF Signaling and mRNA Transcripts in Axons**

Neurotrophic signaling is essential for the development of the sympathetic nervous system. The binding of neurotrophins to Trk receptors induces a variety of cellular processes required for neuronal survival, axon growth, and target innervation. In the absence of Tp53inp2 expression, sympathetic axons demonstrated decreased levels of neuronal survival and growth, which can be attributed to the impaired retrograde transport of NGF-TrkA receptor complexes. This defect in axonal growth and survival is reflected in the reduced innervation of sympathetic targets, particularly the heart and adrenal gland, in Tp53inp2-deficient mice. The expression of Tp53inp2 in sympathetic neurons is thus crucial for the proper development and function of the sympathetic nervous system, highlighting the importance of this protein in mediating the retrograde signaling of NGF for neuronal survival and target innervation.
(legend on next page)
for survival, axon growth, dendritogenesis, and synaptogenesis (Scott-Solomon and Kuruvilla, 2018), which are principally mediated by transcriptional activation and extensive RNA localization in dendrites and axons (Andreassi et al., 2010, 2018; Cosker et al., 2016). Although it is well known that neurotrophic signaling affects gene transcription, asymmetric localization of RNA, and local translation, whether the opposite event may occur was unknown.

Our findings add to the small but growing list of mRNA transcripts that, in addition to being translated into proteins, harbor coding-independent functions (Nam et al., 2016), such as acting as a sponge for miRNA (Valluy et al., 2015) or as a scaffold for the formation of protein complexes (Berkovits and Mayr, 2015). Importantly, the finding that Tp53inp2 mRNA acts in a coding-independent manner in neurons but is translated in other cell types adds a further layer of complexity to RNA regulation and provides evidence for a new mechanism that exploits the 3' UTR to confer cell-type-specific functions to ubiquitously expressed transcripts.

STAR METHODS

**Detailed methods are provided in the online version of this paper and include the following:**

- **KEY RESOURCES TABLE**
- **CONTACT FOR REAGENT AND RESOURCE SHARING**
- **EXPERIMENTAL MODEL AND SUBJECT DETAILS**
  - Generation of Tp53inp2^fl/fl^ mutant mice
  - Mouse husbandry
  - Primary cultures
  - Mouse cortical neurons
  - PC12 cell line
  - HEK293 cell line
  - HeLa cell line
- **METHOD DETAILS**
  - Adenoviral vectors and Plasmids
  - RNA isolation and RT-qPCR
  - In situ hybridization
  - smFISH
  - Neuronal counts
  - Whole-mount diaminobenzidine-TH immunohistochemistry
  - Neuronal survival

- **QUANTIFICATION AND STATISTICAL ANALYSIS**
  - Axon growth
  - Polysomal Fractionation
  - Mass Spectrometry
  - NanoLC-MS/MS analysis
  - RNA Immunoprecipitation
  - Immunoprecipitation and immunoblotting analyses
  - pTrkA Immunostaining
  - Analyses of surface TrkA, receptor endocytosis, and total TrkA

**SUPPLEMENTAL INFORMATION**

Supplemental Information includes four figures and two tables and can be found with this article online at https://doi.org/10.1016/j.neuron.2019.02.011.

**ACKNOWLEDGMENTS**

We thank C. Gerfen (NIH, USA) for the kind gift of the TH-Cre mice, R. Luisier (The Francis Crick Institute, London) for providing the 3' RNA-seq track for Tp53inp2 in Figure S1B, and A. Zorzano (IRB, Barcelona) for the generous gift of the Tp53inp2 antibody. We thank Adolfo Saiardi, Alison Lloyd, Jernej Ule, Haqing Zhao, and Sameer Hattar for insightful suggestions regarding the manuscript and all members of the Riccio and Kuruvilla labs for helpful discussions. This work was supported by Wellcome Trust investigator award 103717/Z/14/Z (to A.R.), MRC senior non-clinical fellowship SNCF G0802010 (to A.R.), MRC LMCB core grant MC_U122668, Wellcome Trust institutional strategic support fund 2014 (to C.A.), NIH R01 DK108267 and NS073751 (to R.K.), NIH training grant T32GM007231 (to C.B.-C. and E.S.-S.), and MIUR, Programma Operativo Nazionale, iCARE Project grant iCARE PON03PE_0009_2 (to M.G.).

**AUTHOR CONTRIBUTIONS**

H.C., E.S.-S., C.B.-C., A.R., and R.K. conceived the work. H.C., C.B.-C., E.S.-S., C.A., E.L., M.H., and M.C.-J. performed the experiments. M.G. performed the mass spectrometry analysis. A.R. and R.K. wrote the manuscript with input from all authors.

Further information and requests for resources and reagents should be directed to and will be fulfilled by the Lead Contact, Antonella Riccio (a.riccio@ucl.ac.uk).

EXPERIMENTAL MODEL AND SUBJECT DETAILS

Generation of Tp53inp2^{fl/fl} mutant mice

ES cells containing the Tp53inp2^{tm1a(KOMP)Mbp} targeting vector were obtained from the trans-NIH Knock-Out Mouse Project (KOMP) Repository (https://www.komp.org/) and used by transgenic core facility at Johns Hopkins University to generate chimeric mice carrying the Tp53inp2^{tm1a} allele. Tp53inp2^{tm1a} chimeric male mice were mated to wild-type albino mice (Jackson Laboratory Stock No: 000058). Tp53inp2^{tm1a} mice carry a knockout-first allele, in which a promoterless cassette including LacZ and neo genes were inserted in intron 1 of the Tp53inp2 gene. For the sympathetic neuron-specific conditional knockout mice, Tp53inp2^{tm1a} mice were crossed with a ubiquitously-expressing Flippase line 129S4/SvJaeSor-Gt(ROSA)26Sortm1(FLP1)Dym/J (Jackson Lab) to excise the LacZ/neo cassette. These mice were then crossed with TH-Cre transgenic mice (gifted by Dr. C. Gerfen NIH) to generate mice lacking Tp53inp2 in sympathetic neurons. The offspring of these mice were then backcrossed for 2-3 generations to C57/BL6 mice to obtain offspring of several genotypes including Th-Cre;Tp53inp2^{fl/fl} mice and control Tp53inp2^{fl/fl} littermates.

Primers Tp53inp2Loxp3F and Tp53inp2Loxp3R which span the third loxP site, were used to genotype the Tp53inp2 allele by PCR, with expected band sizes being 240 bp for wild-type, and 310 bp for the floxed exon. See Table S2 and Key Resources Table for primer sequences.

Mouse husbandry

Mice were housed in a standard 12:12 light-dark cycle. Both sexes were used for analyses. The ages of mice are indicated in the figure legends or methods. All procedures relating to animal care and treatment conformed to Johns Hopkins University Animal Care and Use Committee (ACUC) and NIH guidelines, or the Institutional Animal Care and Use Committee at University College London.

Primary cultures

Superior cervical ganglia (SCG) were dissected from postnatal day 0 or 1 (P0 or P1) Sprague Dawley rats or Tp53inp2^{fl/fl} mice and immediately plated as explant tissue or enzymatically dissociated and cultured either in compartmentalised chambers or as mass cultures. Rats of both sexes were used for analyses. For immunocytochemistry, cells were plated on poly-D-lysine-coated (1 µg/ml) coverslips. Campenot compartmentalised cultures were established as described previously (Riccio et al., 1997). Neurons were cultured in high-glucose DMEM supplemented with 10% FBS, 2 mM glutamine and 100 ng/ml NGF. The antimitotic inhibitor cytosine arabinoside (10 µM) was provided to minimize non-neuronal, contaminating cell types. When indicated, the cell body cluster was removed surgically using a scalpel. To withdraw NGF before any stimulation experiments, neurons were placed in DMEM containing 0.5% FBS with 1:1000 anti-NGF antibody (N6655, Sigma) and BAF (50 µM; MP Biomedical) for 48 hours. For restimulations, neurons were treated with the indicated concentration of NGF for variable amounts of time as indicated.

Mouse cortical neurons

Cortical neurons were dissected from E15.5 C57BL/6J mouse embryos and enzymatically dissociated. Embryos of both sexes were used for analyses. Neurons were plated on Nunc dishes coated with 40 µg/ml poly-D-lysine and 2 µg/ml Laminin and cultured in MEM

Continued
supplemented with 10% FBS and 5% Horse serum. After 6-24 h, culture medium was replaced with Neurobasal medium supplemented with B27, 1 mM glutamine, penicillin-streptomycin and 10 μM 5-Fluoro-2’-deoxyuridine (FdU, Merck). Cells were cultured at 37°C, 5% CO2 and one day before the experiment, 2/3 plating medium was replaced with medium without B27 (serum starve conditions).

**PC12 cell line**
PC12 cell lines were purchased from ATCC. PC12 cells were cultured in DMEM containing 10% FBS, 5% Horse Serum (HS), 2 mM glutamine and grown at 37°C 10% CO2. Cells were transfected with Lipofectamine 2000 in OptiMEM according to the manufacturer’s guidelines. For NGF stimulation, cells were cultured in DMEM containing 0.5% FBS, 0.25% HS, 2 mM glutamine and 50 ng/ml NGF for 4 days under standard growth conditions. Cells were not cultured past 20 passages and sensitivity to NGF stimulation routinely tested. The Nnr5 PC12 subclone cell line was a kind gift from David Ginty’s Laboratory. Nnr5 cells were cultured in DMEM containing 10% FBS, 5% Horse Serum (HS), 2 mM glutamine and grown at 37°C 10% CO2. Cells were transfected with Lipofectamine 2000 in OptiMEM according to the manufacturers’ guidelines.

**HEK293 cell line**
The HEK293 cell line was purchased from ATCC and not further authenticated. HEK293 cells were cultured in DMEM containing 5% FBS, penicillin/streptomycin, 2 mM glutamine and grown at 37°C 5% CO2. Cells were transfected with Lipofectamine 2000 in OptiMEM according to the manufacturers’ guidelines. Cells were not cultured past 20 passages.

**HeLa cell line**
The HeLa cell line was purchased from ATCC and not further authenticated. HeLa cells were cultured in MEM containing 5% FBS, penicillin/streptomycin, 2 mM glutamine and grown at 37°C 5% CO2. Cells were transfected with Lipofectamine 2000 in OptiMEM according to the manufacturers’ guidelines. For cyclohexamide analysis, cyclohexamide was added directly to the growth media at a final concentration of 20 μg/ml and cells were maintained in culture for times indicated. Cells were not cultured past 20 passages.

**METHOD DETAILS**

**Adenoviral vectors and Plasmids**
Rat Tp53inp2CDS was amplified from SCG cDNA and cloned into pCMV-Myc (Clontech) using Sall and BglII to generate Myc-Tp53inp2CDS plasmid. Tp53inp2CDS-2xFlag was PCR amplified from Myc-Tp53inp2CDS plasmid, using primers that encode KpnI/XbaI and C terminus 2xFlag tag. Tp3inp2 3’UTR 1.2, 2.2 and 3.1 Kb and 5’UTR were PCR amplified from RACE clones (C.A. and A.R., unpublished data) and following NotI/Xhol and BamHI/NheI digestion respectively, were used to replace the IMPA UTRs in myrdEGFP-IMPA1-L (Andreassi et al., 2010). Mutation of the ATG codons to generate ATGNullCDS was performed on Myc-Tp53inp2CDS using the QuikChange Site-Directed Mutagenesis kit (Agilent) according to manufacturer’s instructions. The ATGU6nullT35inp2 CDS was then PCR amplified and used to replace the myrdEGFP sequence in the myrdEGFP-Tp35inp2 3.1 Kb UTR vector to create ATGNull Tp35inp2. Rat Tp35inp2 5’UTR + CDS was amplified from SCG cDNA to include endogenous Kozack sequence, and cloned in place of the ATGNull CDS to generate WT Tp35inp2 vector. To generate adenoviral vectors, WT Tp35inp2 and ATGNull Tp35inp2 were amplified using primers containing KpnI and EcoRV and inserted into pCMV-Shuttle plasmid (Agilent). Adenoviral vectors were generated using the AdEasy Adenoviral Vector system (Agilent) according to manufacturer’s instructions. Adenoviral vectors were transfected into HEK293 cells and high-titer viral stocks were prepared using a CsCl gradient. Tp35inp2CDS-1xFlag and ATGNull CDS-1xFlag were PCR amplified from Myc-Tp35inp2CDS and ATGNull CDS Tp35inp2 respectively and following BamHI/NorI digestion were cloned into pcDNA3.1. Primers used for cloning are listed in Table S2.

**RNA isolation and RT-qPCR**
Samples were washed with PBS and RNA was extracted using Trizol reagent following standard manufacturer’s protocol. RNA pellet was resuspended in water and contaminating genomic and plasmid DNA removed by DNase digestion with TURBO DNase. PCR was performed to amplify Actin gDNA or plasmid DNA prior to reverse transcription to confirm DNase digestion. For cell bodies excised from explants of sympathetic neurons used in the axonal TrkA signaling assays, RNA was isolated using RNAquesous-Micro Total RNA Isolation Kit (ThermoFisher) per manufacturer’s protocol with recommended DNase treatment. Total RNA was reverse transcribed using random hexamers and SuperscriptIII reverse transcriptase. RT-qPCR was performed using 20 μL reactions using MESA Blue (Eurogentec), SYBR green or SYBR Select master mix in the Mastercycler realexp qPCR machine (Eppendorf) or CFX Connect RT-PCR machine (BIORAD). Reactions were performed in triplicate and a no template control. For absolute quantification, a standard curve was included, generated through serial dilutions of known concentration of the DNA ampiclon for each primer set. For relative quantification, the power(2,-Ct) of the experimental gene was normalized by the power(2,-Ct) of a housekeeping gene and then expressed as fold change relative to a control. Following 40 cycles, a dissociation curve was performed to assess melting temperature of amplicons. The primers used for RT-qPCR in this study are listed in Table S2.
**In situ hybridization**

In situ hybridization was performed using a digoxigenin-labeled probe spanning a 450-bp region within exons 2-3 of mouse Tp53inp2. Embryos or torsos at various developmental stages were fresh frozen in OCT and serially sectioned (12 μm) using a cryostat. Tissue sections from different developmental stages were collected and processed simultaneously. Sections were post-fixed in 4% PFA-PBS, washed in PBS and acetylated with 0.25% acetic anhydride in 0.1 M triethanolamine with 0.9% NaCl. After hybridization with the labeled RNA probe (2 μg/ml) at 68 °C o/n, sections were washed with 0.2x SSC buffer at 65 °C, blocked with TBS containing 1% normal goat serum and then incubated with alkaline phosphatase-labeled anti-DIG antibody (1:5,000; Roche) o/n at 4 °C. The alkaline phosphatase reaction was visualized with NBT/BCIP, rinsed in PBS, fixed in 4% PFA-PBS and mounted in AquaMount (EMD Chemicals).

**smFISH**

smFISH was performed as described (Chen et al., 2015; Raj et al., 2008) with minor modifications. Sympathetic neurons were cultured 3-7 days in vitro on glass coverslips, washed with PBS at room temperature (RT) and fixed using 3.7% PFA-PBS RT 10 min. Cells were permeabilised with 70% EtOH at 4 °C for 3 h. Coverslips were prehybridized in 2xSSC 10% formamide for 5 min RT then incubated at 37 °C o/n with Cy3 labeled probe sets designed against Tp53inp2 3'UTR (Stellaris probes, Biosearch technologies) in hybridization buffer (10% formamide, 2x SSC, 10% dextran sulfate and 2 mM vanadyl ribonucleoside). Cells were rinsed in warm 2x SSC 10% formamide and then 5-(4,6-dichlorotrizinyl) aminofluorescein (DTAF) (Thermo Fischer, D16), a reactive dye that labels amines in proteins, was added at 1:10,000 (stock 10 mg/ml) in GLOX buffer for 10 min as a counterstain. Cells were then rinsed in 2x SSC and mounted using Aquamount containing 1:1000 DAPI.

**Neuronal counts**

The torsos of Tp53inp2fl/fl or Th-Cre;Tp53inp2fl/fl E16.5, P0.5 and P21 mice were immersion fixed in 4% PFA-PBS for 4 h (E16.5, P0.5), or overnight (P21) respectively. The heads were then cryoprotected overnight (for E16.5 and P0.5) or 2 days (P21) in 30% sucrose-PBS, frozen in OCT and then serially sectioned (12 μm). Tissue sections were stained with a solution containing 0.5% cresyl violet (Nissl). Cells with characteristic neuronal morphology and visible nucleoli were counted in every fifth Nissl-stained section. For representative images, immunohistochemistry was performed on tissue sections. Sections were first blocked in a PBS buffer containing 5% goat serum and 0.1% triton and then incubated overnight in rabbit anti-TH (1:200; Millipore AB152). Following PBS washes; sections were incubated with anti-rabbit Alexa 488 secondary antibodies (1:200; Life Technologies). Sections were then washed in PBS and mounted in VectaShield (Vector Laboratories). For practical reasons, analyses were done in a semi-blinded manner, with the investigator knowing the genotypes prior to the experiment, yet performed the staining and quantification without knowing the genotype of the sample.

**Whole-mount diaminobenzidine-TH immunohistochemistry**

E16.5 embryonic organs fixed in 4% PFA-PBS were dehydrated by methanol series (50%–80%) and incubated overnight in 20% dimethylsulfoxide (DMSO)/80% methanol solution containing 3% H2O2 to quench endogenous peroxidase activity. Tissues were then re-hydrated, blocked o/n in blocking solution (4% BSA/1% Triton X-100 in PBS) using a rabbit anti-TH (Millipore, AB152) diluted at 1:200 in blocking solution and incubated for 72 h at 4 °C. Detection was performed with horseradish peroxidase-conjugated donkey anti-rabbit IgG (GE Healthcare) at 1:200 in blocking solution and incubated o/n at 4 °C. Visualization was accomplished with diaminobenzidine. Tissues were re-fixed in 4% paraformaldehyde-PBS, dehydrated by methanol series and cleared with a 2:1 mixture of benzyl benzoate/benzyl alcohol to allow visualization of staining inside the tissue followed by clearing. For practical reasons, analyses were done in a semi-blinded manner, with the investigator knowing the genotypes prior to the experiment, yet performed the staining and quantification without knowing the genotype of the sample.

**Neuronal survival**

SCG neurons isolated from P0.5-P2 Tp53inp2fl/fl were grown in Campenot chambers for 9 days in vitro. NGF was removed and neurons were infected for 48-72 h with either LacZ or Cre adenovirus. FluoSpheres (ThermoFisher: F8789) were added to axonal compartments to label projecting neurons. Neurons were starved of NGF and restimulated with 25 ng/ml NGF for 48 h or left deprived. To detect neuronal death, neurons were fixed in 4% PFA-PBS for 30 min at room temperature followed by permeabilisation with 0.1% Triton/PBS for 10 min. After extensive PBS washes, dying neurons were visualized using TUNEL staining (Roche: 11684795910) and mounted in Fluoromount with DAPI (1:1000). Neuronal apoptosis was calculated by determining the percentage of neurons that had extended to distal compartments that were also TUNEL positive. Between 30-50 neurons were counted per condition in each experiment.

**Axon growth**

Compartmentalised neuronal cultures from P0.5 Tp53inp2fl/fl neurons were infected with LacZ or Cre adenovirus after 7-10 days in vitro after axons had extended into the side compartments. Neurons were either deprived or treated with NGF (100 ng/ml) added solely to the axonal compartments, and axon growth was measured by capturing phase contrast images of the distal axons over consecutive 24 h intervals for 3 days, using a Zeiss Axiovert 200 microscope with a Retiga EXi camera. The rate of axonal growth...
(μm/day) was quantified using Openlab 4.04. For representative images, neurons were immunostained with β-III-tubulin (1:200; Sigma-Aldrich T8660) 48 h after treatment.

Polysomal Fractionation
SCG neurons were cultured for 7 days under NGF stimulation, then ribosomes were immobilised with 0.1 mg/ml cyclohexamide added directly to growth media for 3 min at 37°C. Cells were washed 2x on ice with cold PBS + 0.1 mg/ml cyclohexamide and lysed in 10 mM Tris pH8, 150 mM NaCl, 5 mM MgCl2, 1% NP40, 10 mM VRC, 1% sodium deoxycholate, 40 mM DTT, 500 U/ml RNaseOUT. Nuclei were removed by a brief centrifugation and supernatants were supplemented with 0.1 M Tris pH7.5, 150 mM NaCl, 75 μg/ml cyclohexamide, 1:100 protease inhibitor cocktail, followed by further centrifugation to remove any insoluble material. Lysates were loaded on top of 15%–40% sucrose gradients, prepared in 10 mM Tris pH7.5, 140 mM NaCl, 1.5 mM MgCl2, 10 mM DTT, 0.1 mg/ml cyclohexamide, and subjected to ultracentrifugation in Beckman SW41Ti rotor 2 h 4°C 25000xg. Nineteen fractions were collected and digested with proteinase K (100 μg proteinase K, 0.1% SDS, 10 mM EDTA) for 30 min at 37°C. To normalize for RNA loss during extraction, 2.5 ng of in vitro transcribed RNA was spiked to each fraction prior to phenol:chloroform extraction. Twenty-five per cent of sample was precipitated for RT-qPCR, and the remainder was precipitated for denaturing agarose gel electrophoresis to assess quality of the fractionation. RNA was run on 1% agarose MOPS gel under denaturing conditions and the gel was stained with SYBRGold prior to imaging.

Mass Spectrometry
PC12 cells transfected with a plasmid expressing Myc-Tp53inp2 were washed with cold PBS and lysed in cold RIPA buffer (50 mM Tris pH 7.4, 150 mM NaCl, 0.5% sodium deoxycholate, 1% NP40, 1:100 Protease inhibitor cocktail). Lysates were sheared through a 25 G needle and protein content was quantified by BCA assay according to manufacturer’s instructions (Pierce). 2 μg Myc 9E10 antibody (Ab32, Abcam) was conjugated to protein G-Sepharose (GE Healthcare Life Science) o/n rotating at 4°C. Bound antibody was then cross-linked to the beads with 2x30 min RT rotation with 6.5 mg/ml DMP (Thermo Fisher Scientific) in 0.2 M pH8.2 triethanolamine, followed by 30 min RT blocking in 100 mM pH8.2 ethanalamine. Beads were washed extensively with PBS and the unbound antibody eluted with 0.1 M Glycine 10 min RT. Following further PBS washes of beads, 300 μg of protein lysate was added and incubated o/n rotating at 4°C. Beads were washed 3 times 10 min in wash buffer (10 mM Tris pH 7.4, 150 mM NaCl, 1 mM EDTA pH 8.0, 1 mM EGTA pH 8.0, 0.1% Triton X-100) followed by a final PBS wash. Samples were then subjected to on-bead digestion using 200 ng sequencing grade trypsin in 300 μL 100 mM Tris pH8 15 min 37°C. Beads were pelleted by centrifugation and supernatant collected and analyzed by mass-spectrometry. Lyophilised samples were reconstituted in HPLC-grade water and reduced with 10 mM DTT 1h at 37°C, followed by cysteine alkylation (25 mM iodoacetamide, 1 h at 37°C in the dark); excess iodoacetamide was quenched by 1 μL of 100 mM DTT. Full trypic digestion was achieved by an additional overnight incubation in presence of 200 ng of trypsin proteomics grade. Peptides were purified by strong cation exchange (SCX) extraction tips (Rappsilber et al., 2007), and eluted in 7 μL of 500 mM ammonium acetate containing 20% acetonitrile v/v. A 10% aliquot of the IP digest was injected for nanoLC-MS/MS analysis in data-dependent mode.

SCG explants were cultured under NGF stimulation for 7 days and axons surgically dissected from cell body. Axon and cell body samples were then lysed in cold RIPA buffer, quantified by BCA and analyzed by mass-spectrometry. Proteins were precipitated by adding four volumes of cold acetone, and by incubating the solution at –20°C for 1 h. After a centrifugation step carried out at 12,000xg for 20 min 4°C, the supernatant was discarded, and the pellet was resuspended in buffer containing 8 M urea, 100 mM Tris pH 8.5 and 0.2% w/v SDS. Protein reduction and alkylation was performed as described above. The protein solution was brought to a final volume of 400 μL by adding HPLC-grade water to reduce urea and SDS concentrations. Finally, 2 μg of trypsin proteomics grade was added to each sample and incubated o/n at 37°C with agitation. The digests were diluted 8-fold in 80% acetonitrile/0.5% formic acid before being loaded onto SCX extraction tips. For targeted analysis, 30 μL of the initial digest solutions were loaded on SCX extraction tips and then eluted in 7 μL of 500 mM ammonium acetate containing 20% acetonitrile v/v; the eluate was evaporated to dryness and reconstituted in 20 μL of mobile phase A (0.1% formic acid, 2% acetonitrile); a 3 μL aliquot was then injected for nanoscale liquid chromatography coupled to tandem mass spectrometry (nanoLC-MS/MS) analysis.

NanoLC-MS/MS analysis
Proteomic analysis by nanoLC-MS/MS was essentially performed as described in Taverna et al. (2017). Briefly, peptides were loaded directly on-column at 500 nL/min and separated at 300 nL/min via a 60-min gradient ramped from 5% to 35% mobile phase B (80% acetonitrile, 0.1% formic acid); mobile phase A was 2% acetonitrile, 0.1% formic acid. The analytical column, a pulled 75 μm i.d capillary in-house packed to a length of 12 cm, was connected to a liquid chromatography system (EasyLC 1000, Thermo Fisher Scientific) and directly interfaced to a quadrupole-orbitrap mass spectrometer Q-Exactive (Thermo Fisher Scientific) via a nanoelectrospray interface operating in positive ion mode. Data-dependent acquisition was performed using a top-12 method. Full scan parameters were: resolution 70,000, m/z range 350-1800. Tandem mass spectrometry parameters were: resolution 17,500, isolation window 1.6 m/z, maximum injection time 60 ms, AGC target 100,000, normalized collision energy 25, dynamic exclusion 30 s. Data were processed using Proteome Discoverer 1.3 (Thermo Fisher Scientific), Tandem mass spectrometry data were searched against the Rattus norvegicus Uniprot database (downloaded on 03/2015) merged with a list of common contaminating proteins (albumin, trypsin, human keratins). Sequest search parameters were: MS tolerance 20 ppm; MS/MS tolerance 0.02 Da; oxidised
methionine (variable); carbamidomethyl cysteine (static); enzyme trypsin; maximum missed cleavages 2. Search results were filtered by Percolator (Spivak et al., 2009), integrated in Proteome Discoverer, using default parameters. Protein hits based on two-high-confidence peptide identifications (q-value < 0.01) were considered valid.

For targeted mode of analysis, the Orbitrap analyzer was operated in targeted MS/MS mode: a single full MS scan (17,500 resolution, 500,000 target ions) was followed by three targeted MS/MS events on precursors at 420.2 (ALHHAAAPmoxPAR, z = 3), 507.6 (HQGSFYIPQCQR, z = 3), 414.9 (ALHHAAAPmPAR, z = 3) m/z. MS/MS conditions were, in all cases, the following: MS resolution 70,000, maximum injection time 250 ms, isolation window 2.0 m/z, AGC target 200,000, normalized collision energy 25.

RNA Immunoprecipitation
Four μg Trk antibody (Santa Cruz sc7268), HuD antibody (Santa Cruz sc28299), NCAM-L1 antibody (Santa Cruz sc514360) or Mouse IgG antibody (Santa Cruz sc2027) were incubated with prewashed protein A/G agarose beads (Santa Cruz) in a PBS buffer containing 1 mg/ml heparin and 1% BSA for 2 h 4°C, and then washed with wash buffer (50 mM Tris pH8, 150 mM NaCl, 1% Triton X-100). Rat SCG neurons or mouse cortical neurons were cultured 5-7 days in vitro and then, for SCG cultures, depriv of NGF for 24 h before stimulating for 30 min with NGF or leaving unstimulated. Cultures were washed with PBS and lysed in Buffer A (50 mM Tris pH8, 150 mM NaCl, 1% Triton X-100, 1:100 Protease inhibitor cocktail, 500 U/ml RNaseOUT) 10 min 4°C. Insoluble material was removed by centrifugation, a 10% fraction saved for total input, and lysates were incubated with antibody conjugated beads for 1 h at 4°C in wash buffer containing 0.2 mg/ml heparin. Beads were washed 3 times with wash buffer 10 min 4°C followed by elution of RNA in extraction buffer (0.2 M NaAcetate, 1 mM EDTA, 0.2% SDS) for 5 min at 70°C. RNA was purified from inputs and immunocomplexes using PureLink® RNA Micro Scale Kit according to manufacturer’s instructions and analyzed by qRT-PCR.

Immunoprecipitation and immunoblotting analyses
SCGs were isolated from P0-P3 Tp53inp2fl/fl mice and grown as explant cultures. After 7-8 days in vitro, NGF was removed and neurons infected for 48 h with either LacZ or Cre adenovirus. Cell bodies were surgically removed and the axons were stimulated with 50 ng/ml NGF for 30 min or treated with anti-NGF antibody. Three to seven explants per condition were lysed in RIPA buffer with 2.5 mM sodium pyrophosphate, 50 mM sodium fluoride, 1 mM sodium orthovanadate and protease inhibitors. To detect P-TrkA, axon lysates were subjected to immunoprecipitation with anti-phosphotyrosine antibody (PY-20; 4 μl; Sigma-Aldrich) and incubated with Protein G-Plus (Santa Cruz; sc-2002) agarose beads. Immunoprecipitates were then immunoblotted for TrkA (1:1000 Millipore; 06-574). The supernatants from the immunoprecipitations were subjected to immunoblotting with pAkt (1:1000 Cell Signaling; 9271), pErk1/2 (1:1000 Cell signaling; 9106) and p85 antibodies (1:1000 Upstate Biotechnology, 06-195). All immunoblots were visualized with ECL Plus Detection Reagent (GE Healthcare) and scanned with a Typhoon 9410 Variable Mode Imager (GE Healthcare).

For Trk and HuD immunoprecipitations, PC12 cells or SCG neurons were lysed in RIPA buffer (50 mM Tris-HCl pH 7.4, 150 mM NaCl, 1% NP-40, 0.5% Sodium deoxycholate, 0.1% SDS, 1 mM EDTA, Protease Inhibitors Cocktail) for 10 min on ice, and then insoluble material was removed by centrifugation. Lysates were pre-cleared and 0.5-1 mg of lysate was incubated o/n at 4°C with 2 μg of indicated antibody. Immunocomplexes were precipitated by the addition of protein A-agarose beads at 4°C for 2 h, and then beads washed extensively with RIPA buffer. Samples were eluted from beads by boiling at 95°C in 1x LDS buffer + 10% b-mercaptoethanol and resolved on polyacrylamide gels.

In all western blots, cell lysates were prepared in 1x NuPAGE LDS buffer + 10% b-mercaptoethanol, mechanically disrupted by syringing and boiled at 95°C for 5 min before loading. The primary antibodies used were goat anti-Tp53inp2 (1:250 Santa Cruz sc85972), rabbit anti-Tp53inp2 (1:200 generated by Riccio Laboratory) rabbit anti-Tp53inp2 (1:500 a kind gift from Zorzano Laboratory; Baumgartner et al., 2007), rabbit anti-Tp53inp2 (1:1000 Sigma AB4502917) mouse anti-Flag (1:1000 Sigma F3165), rabbit anti-Flag (1:1000 Sigma F7425), goat anti-Hsp90 (1:1000 Santa Cruz sc1055), mouse anti-Myc (1:2000 Upstate 05-724), rabbit anti-p85 PI3K (1:1000 Upstate 06-497), mouse anti-α-Tubulin (1:10000 Sigma T9026), chicken anti-GFP (1:5000 Abcam ab13970) mouse anti-mCherry (1:4000 Abcam ab125096), mouse anti-HuD (1:1000 Santa Cruz sc28299), mouse anti-TrkA (1:1000 Santa Cruz sc7268) mouse anti-NCAM (1:1000 Santa Cruz sc14360). The HRP-conjugated secondary antibodies used were anti-mouse (GE Healthcare life sciences) anti-rabbit (GE Healthcare life sciences), anti-goat (Sigma), anti-chicken (Sigma). Signal was detected using ECL or ECL Prime (GE Healthcare Life Science) and exposing membrane to Amersham Hyperfilm (GE Healthcare Life Science).

pTrkA Immunostaining
SCG neurons isolated from P0-P3 Tp53inp2fl/fl mice were grown in Campenot chambers for 8-10 days in vitro. NGF was removed and neurons infected for 48 h with either LacZ or Cre adenovirus. FluoSpheres were added to axonal compartment to label projected neurons. Distal axons were treated for 4 h with either 50 ng/ml NGF or anti-NGF antibody. To detect pTrkA in the cell bodies induced by retrograde NGF signal, neurons were fixed in 4%PFA-PBS for 30 min at room temperature and blocked in a PBS buffer containing 5% Goat Serum and 0.1% TritonX for 1 h. Neurons were incubated with rabbit anti-pTrkA (1:1000; Cell Signaling Technology, 4168S) and mouse anti-TH antibodies (1:1000, Sigma, T2928) in a PBS buffer containing 1% Goat Serum and 0.1% Triton, o/n at 4°C. Following extensive washes with PBS, neurons were incubated with fluorescently conjugated anti-rabbit (ThermoFisher, A11008) and anti-mouse antibodies (Thermo Fisher, A21240) secondary antibodies at 1:1000 dilution, 37°C for 2 h. Slides were mounted in Fluoromount (Sigma) with DAPI. Images representing 0.8 μm slices were acquired using a Zeiss LSM 700 confocal scanning microscope. The same confocal settings were used to acquire all images taken from a single experiment. For practical reasons,
analyses were done in a semi-blinded manner, with the investigator knowing the genotypes prior to the experiment, yet performed the staining and quantification without knowing the genotype of the sample. Total pTrkA positive punctae were quantified using Particle Analyses for 20-30 neurons per condition.

**Analyses of surface TrkA, receptor endocytosis, and total TrkA**

Live-cell antibody feeding to monitor surface TrkA and receptor endocytosis were performed as previously described (Yamashita et al., 2017). Cultured sympathetic neurons isolated from Tp53inp2fl/fl mice were infected o/n with a doxycycline-inducible Flag-TrkA adenovirus, and either LacZ or Cre adenovirus. Neurons were then treated with doxycycline (200 ng/mL, 18 hr) to induce Flag-TrkA expression. Surface Flag-TrkA was labeled by incubating neurons with anti-Flag antibody (Sigma, F7425, 1:500) in PBS for 30 mins at 4°C in the absence of NGF. Excess antibody was washed off with ice-cold PBS, and neurons either immediately fixed with 4% PFA/PBS for 30 mins to assess surface Flag-TrkA distribution, or treated with anti-NGF or NGF (50 ng/mL) for another 30 min to assess receptor internalization. Following treatment with NGF or anti-NGF, neurons were returned to 4°C and quickly washed in ice-cold acidic buffer (0.2 M acetic acid, 0.5 M NaCl, pH 3.0) to strip surface-bound Flag antibodies and fixed. Neurons were permeabilised with 0.1% Triton X-100/5%Normal Goat Serum/PBS and receptors visualized by incubation with anti-rabbit-Alexa 488 secondary antibody. Neuronal morphology was visualized by co-staining with anti-β-tubulin III antibody (Sigma-Aldrich, T8660, 1:1000). Images representing 0.8 μm slices were acquired using a Zeiss LSM 700 confocal scanning microscope. The same confocal settings were used to acquire all images taken from a single experiment. For practical reasons, analyses were done in a semi-blinded manner, with the investigator knowing the genotypes prior to the experiment, yet performed the staining and quantification without knowing the genotype of the sample. Surface Flag-TrkA receptor distribution was analyzed by measuring the integrated fluorescence values along the longest axis of the cell body using line-plot in ImageJ and normalized to the total cell body fluorescence intensity. Intracellular accumulation of Flag-TrkA receptors in cell bodies were quantified as the number of FLAG-immunopositive punctae per neuron. Cell bodies were visualized using the GFP signal and FLAG signals overlapping with GFP fluorescence were defined as internalized soma surface-derived receptors. To assess Flag-TrkA internalization, cell bodies or axons were outlined using β-tubulin III immunostaining and internalized receptors calculated as integrated density of Alexa 488 pixels per μm² (cell bodies) or Alexa 488 pixels per μm (axons).

Cell surface biotinylation was performed on Tp53inp2fl/fl neurons as previously described (Houtz et al., 2016). Briefly, Tp53inp2fl/fl neurons, infected with either LacZ or Cre adenoviruses, were deprived of NGF in the media after a culture period of 8-10 d.i.v. and biotinylated at 4°C with a reversible membrane-impermeable form of biotin (EZ-Link NHS-SS-Biotin, 1.5 mg/ml in PBS, ThermoFisher Scientific, Cati 21441) for 30 min. Cells were washed briefly with PBS containing 50 mM glycine (Sigma) to remove remaining unconjugated biotin, and then moved to 37°C and stimulated with NGF (50 ng/mL) for 30 min to promote internalization. Cells were returned to 4°C, the remaining biotinylated surface receptors were stripped of their biotin tag with 50 mM glutathione (Sigma), followed by two washes with 50 mM iodoacetamide (Sigma) to quench excess glutathione. Cells were lysed with 500 μl of RIPA buffer (50mM Tris-HCl, 150 mM NaCl, 1 mM EDTA, 1% NP-40, 0.25% deoxycholate), and supernatants subjected to precipitation with 40 μl-immobilized neutravidin agarose beads (ThermoFisher Scientific) and immunoblotted for TrkA.

**QUANTIFICATION AND STATISTICAL ANALYSIS**

Data are expressed as average ± SEM. One-way ANOVA, two-way ANOVA, Mann-Whitney two-tailed test, or t test were used as indicated in the figure legends to test for statistical significance using GraphPad Prism. n values are indicated in the corresponding figure legends. Significance was placed at p < 0.05 unless otherwise noted in the figure legends. Statistical methods were not used to determine sample size, but sample size was selected based on similar studies within the field.

**DATA AND SOFTWARE AVAILABILITY**

The datasets generated during the current study are available from the corresponding author on reasonable request.
