The Yamabe invariant for non-simply connected manifolds

Boris Botvinnik and Jonathan Rosenberg

November 15, 2018

Abstract

The Yamabe invariant is an invariant of a closed smooth manifold defined using conformal geometry and the scalar curvature. Recently, Petean showed that the Yamabe invariant is non-negative for all closed simply connected manifolds of dimension $\geq 5$. We extend this to show that Yamabe invariant is non-negative for all closed manifolds of dimension $\geq 5$ with fundamental group of odd order having all Sylow subgroups abelian. The main new geometric input is a way of studying the Yamabe invariant on Toda brackets. A similar method of proof shows that all closed manifolds of dimension $\geq 5$ with fundamental group of odd order having all Sylow subgroups elementary abelian, with non-spin universal cover, admit metrics of positive scalar curvature, once one restricts to the “complement” of manifolds whose homology classes are “toral.” The exceptional toral homology classes only exist in dimensions not exceeding the “rank” of the fundamental group, so this proves important cases of the Gromov-Lawson-Rosenberg Conjecture once the dimension is sufficiently large.

1 Introduction

The positive solution of the Yamabe problem \cite{23} tells us that if $M$ is a compact smooth manifold (without boundary), then every conformal class $C$ of Riemannian metrics on $M$ contains a metric (known as a Yamabe metric) of constant scalar curvature with the following special property. Its scalar curvature is the infimum of the scalar curvature $s_g$, taken over all metrics in $C$ with constant scalar curvature and total volume 1. The value of this scalar curvature is called the Yamabe constant $Y(M, C)$ of $C$. Equivalently, $Y(M, C)$ can be defined to be the minimum over metrics $g \in C$ of the Einstein-Hilbert functional

$$I(g) = \frac{\int_M s_g \, d\text{vol}_g}{\text{vol}_g(M)^{\frac{n-2}{2}}}.$$
The non-simply connected Yamabe invariant

It is therefore natural to ask if there is a “best” Yamabe metric, and if so what its scalar curvature is. That motivates the following definition from [11]. The Yamabe invariant of $M$ is defined by

$$Y(M) = \sup_C Y(M, C).$$

(1.1)

This supremum is not always attained, so the answer to the question about whether $M$ has a “best” metric of constant scalar curvature might be “no.” The best that is known is that there are singular metrics (with singularities at a finite number of points) which serve as the “best” approximation to an Einstein metric on $M$.

Nevertheless, $Y(M)$ is a diffeomorphism invariant of $M$. It also turns out that $Y(M) > 0$ if and only if $M$ admits a metric of positive scalar curvature, a much-studied condition ([5], [6], [7], [26], [27], [21], [22], [4]). However, $Y(M) = 0$ is possible even when $M$ admits no scalar-flat metric.

In dimension 2, Gauss-Bonnet quickly shows that $Y(M) = 4\pi \chi(M)$. In dimension 4, $Y(M)$ can be positive, 0, or negative, and a lot is known about it from Seiberg-Witten theory ([13] and [14]). Similarly, there is a conjectural connection between $Y(M)$ and “geometrization” when $\dim M = 3$ (see for instance [2]). But even when $\dim M = 3$, and especially when $\dim M > 4$, it is not yet known if there are any manifolds with $Y(M) < 0$. (The obvious candidates for such manifolds are hyperbolic manifolds, but for all we know they could have vanishing Yamabe invariant.) In fact, Petean [17] has proved that $Y(M) \geq 0$ for any simply connected manifold of dimension at least 5.

In this paper we study the Yamabe invariant for manifolds with finite fundamental groups. Our first main result is the following.

**Theorem 1.1** Let $M$ be a closed, connected, compact manifold with finite fundamental group $\pi$, $\dim M \geq 5$. Suppose all Sylow subgroups of $\pi$ are abelian. Assume either that $M$ is spin and the order of $\pi$ is odd, or else that the universal cover of $M$ is non-spin. Then $Y(M) \geq 0$.

The proof of this result is somewhat involved. First of all, we use surgery tools (developed in the study of positive scalar curvature) to reduce the assertion of Theorem [11] to special situations. In particular, we show that it is enough to study the case when $\pi$ is a finite abelian $p$-group. The central objects to understand here are the bordism groups $\Omega(B\pi)$ and $\Omega^{\text{Spin}}(B\pi)$, and the proof amounts to the fact that all elements of these bordism groups may be represented by manifolds with nonnegative Yamabe invariant. A computation of these groups is quite hard, and the actual answer is known only for elementary abelian groups of odd order and few other cases (see [8]). Instead we use the Künneth formula to build manifolds with nonnegative Yamabe invariant to represent generators of these bordism groups. There are two types of “building blocks”: tensor products (which are realized by direct products of manifolds) and torsion products (which geometrically are just Toda brackets).

We recall that Toda bracket $\langle M, P, L \rangle$ is defined when $M \times P = \partial V$ and
The non-simply connected Yamabe invariant

\[ P \times L = \partial U. \]  

Then the manifold

\[ W = V \times L \cup M \times P \times L \times M \times U \]

represents the Toda bracket \( \langle M, P, L \rangle \).

As usual, to prove new geometric results we have to employ some new geometric techniques. Roughly, we show (under some restrictions) that if \( Y(M) \) and \( Y(L) \) are \( \geq 0 \) (resp., > 0), then \( Y(W) \geq 0 \) (resp., > 0). We prove this by analytical means using elementary differential geometry.

Our second main result is the following.

**Theorem 1.2** Let \( M \) be a closed, connected, compact manifold with fundamental group \( \pi \) of odd order. Suppose all Sylow subgroups of \( \pi \) are elementary abelian of rank \( \leq r \). Assume that \( M \) is non-spin and that \( \text{dim} M \geq \max(5, r) \). Then \( M \) has a metric of positive scalar curvature.

To put these results in context, it’s worth recalling what is known about positive scalar curvature for manifolds with finite fundamental group. For such manifolds (of dimension \( \geq 5 \)) whose universal cover is non-spin, there are no known obstructions to positive scalar curvature. For spin manifolds of dimension \( \geq 5 \) with finite fundamental group, the only known obstructions to positive scalar curvature come from the index theory of the Dirac operator \([21], [22]\), and it is known that “stably” these are the only obstructions \([21]\). In fact in \([19]\), it was conjectured (on the basis of extremely spotty evidence) that the index theory of the Dirac operator provides the only obstructions to positive scalar curvature on manifolds of dimension \( \geq 5 \) with finite fundamental group. This conjecture has sometimes been called the Gromov-Lawson-Rosenberg Conjecture. However, the “stable” theorem by itself does not actually answer the question of whether any particular manifold with vanishing Dirac obstructions admits a metric of positive scalar curvature. It is known \([4]\) that for spin manifolds of dimension \( \geq 5 \) with finite fundamental group with periodic cohomology, the Dirac obstructions are the only obstructions to positive scalar curvature. A similar theorem was proved by Schultz \([24]\), and independently by Botvinnik and Gilkey \([3]\), for spin manifolds of dimension \( \geq 5 \) with fundamental group \( \mathbb{Z}/p \times \mathbb{Z}/p \), \( p \) an odd prime. But very little was previously known about positive scalar curvature for manifolds with elementary abelian fundamental group of rank > 2. The proof of Theorem 1.2 is based on a reduction to the results of \([3]\), again using Toda brackets.

The outline of the paper is as follows. Section 2 recalls the surgery and bordism theorems necessary for attacking the problems. Section 3 contains our basic geometric results on Toda brackets. Section 4 puts together the topological and geometrical tools to prove Theorem 1.2 and related results, and Section 5 proves Theorem 1.2 and related results.

We would like to thank Sergey Novikov for his encouragement and support.
## 2 Basic Topological Reduction Tools

To warm up, we recall the following result of Petean for simply connected manifolds:

**Theorem 2.1** ([17]) If $M^n$ is a connected, simply connected closed manifold of dimension $n \geq 5$, then $Y(M) \geq 0$.

The proof of this fact is based on the following surgery theorem:

**Theorem 2.2** (Petean, Yun [18]) If $M$ is a closed manifold with connected components $M_i$, and if another closed connected manifold $M'$ can be obtained from $M$ by surgeries in codimension $\geq 3$, and if $Y(M_i) \geq 0$ for each $i$, then $Y(M') \geq 0$.

*Proof.* This is really three theorems in one. If $Y(M_i) > 0$ for all $i$, then $M$ admits a metric of positive scalar curvature, hence so does $M'$, by the surgery theorem of Gromov-Lawson and Schoen-Yau ([3] and [24]—some of the details are carefully redone in Theorem 3.1 of [22]), and so $Y(M') > 0$. If $M$ is disconnected and $Y(M_i) = 0$ for some components and $Y(M_j) > 0$ for other components, then we may first replace $M$ by the connected sum of its components, which has $Y \geq 0$ by iterated application of case (b) of [18], Theorem 1. (See also [11].) This reduces us to the case where $M$ is connected. If $M$ is connected and $Y(M) \leq 0$, then the Corollary to Theorem 1 of [18] says $Y(M') \geq Y(M)$, so if $Y(M)$ is exactly 0, $Y(M') \geq 0$. □

In this paper we will discuss what can be learned about the Yamabe invariant for non-simply connected manifolds, using Theorem 2.2.

Many of the basic facts about manifolds of positive scalar curvature, which are proved using the surgery theorem of Gromov-Lawson and Schoen-Yau, have obvious counterparts for manifolds with nonnegative Yamabe invariant, obtained by substituting Theorem 2.2 in the proof. The proofs are almost identical to those in the positive scalar curvature case, so while we will give complete statements of the results, we will be brief when it comes to details of the proofs.

First we need to convert the Surgery Theorem, Theorem 2.2, to a Bordism Theorem. We repeat some definitions from [21] and [22]:

**Definition 2.3** Let $B \to BO$ be a fibration. A $B$-structure on a manifold is defined to be a lifting of the (classifying map of the) stable normal bundle to a map into $B$. Then one has bordism groups $\Omega^B_n$ of manifolds with $B$-structures, defined in the usual way. (For instance, if $B = B_{\text{Spin}}$, mapping as usual to $BO$, then $\Omega^B_n = \Omega^{\text{Spin}}_n$.) We note that given a connected closed manifold $M$, there is a choice of such a $B$ for which $M$ has a $B$-structure and the map $M \to B$ is a 2-equivalence.

**Examples 2.4** The following special cases show that many of the classical bordism theories arise via this construction.
1. If $M$ is a spin manifold, choose $B = B\pi \times B\text{Spin}$, where $\pi = \pi_1(M)$, and let $B \to BO$ be the projection onto the second factor composed with the map $B\text{Spin} \to BO$ induced by $\text{Spin} \to O$. Map $M$ to the first factor by means of the classifying map for the universal cover, and to the second factor by means of the spin structure. The map $M \to B$ is a 2-equivalence since it induces an isomorphism on $\pi_1$ and $\pi_2(B) = 0$. The associated bordism theory is $\Omega^\text{Spin}_*(B\pi)$.

2. If $M$ is oriented and the universal cover $\tilde{M}$ of $M$ is non-spin, choose $B = B\pi \times B\text{SO}$, where $\pi = \pi_1(M)$, and let $B = B\text{SO} \to BO$ be the obvious map. Map $M$ to the first factor by means of the classifying map for the universal cover, and to the second factor by means of the orientation. The map $M \to B$ is a 2-equivalence since it induces an isomorphism on $\pi_1$ and $\pi_2(B) \cong \pi_2(B\text{SO}) \cong \pi_1(\text{SO}) \cong \mathbb{Z}/2$, with the map $\pi_2(M) \to \pi_2(B)$ corresponding to $w_2(\tilde{M})$. The associated bordism theory is $\Omega_*(B\pi)$.

3. If $M$ is not orientable and the universal cover of $M$ is non-spin, let $\pi = \pi_1(M)$, and let $B$ be defined by the homotopy pull-back diagram

$$
\begin{array}{ccc}
B & \longrightarrow & B\pi \\
\downarrow & & \downarrow \pi_1 \\
BO & \longrightarrow & \mathbb{RP}^\infty,
\end{array}
$$

where the maps labeled $w_1$ are defined by the first Stiefel-Whitney class. Note that $BO$ has fundamental group $\mathbb{Z}/2$ and that $w_1 : BO \to \mathbb{RP}^\infty$ induces an isomorphism on $\pi_1$, so that $B$ has fundamental group $\pi$. The map $B \to BO$ can be taken to be a fibration with fiber $B\pi'$, where $\pi' = \ker w_1$ is the fundamental group of the oriented double cover of $M$. Then the maps of $M$ to $B\pi$ by means of the classifying map for the universal cover and to $BO$ by means of the classifying map for the stable normal bundle define a map from $M$ to $B$ which is a 2-equivalence for the same reason as in the last example. We will denote the associated bordism theory by $\mathcal{N}_*(B\pi \downarrow \mathbb{RP}^\infty)$: it is a “twisted version” of unoriented bordism with coefficients in $B\pi'$, and it obviously comes with a natural map to $\mathcal{N}_*(B\pi)$. In the special case where $\pi$ splits as $\pi' \times \mathbb{Z}/2$, with $\pi' = \ker(w_1 : \pi \to \mathbb{Z}/2)$, then $B$ becomes simply $B\pi' \times BO$, and the associated bordism theory is $\mathcal{N}_*(B\pi')$. In general, $\mathcal{N}_*(B\pi \downarrow \mathbb{RP}^\infty)$ is more complicated to describe, though the following proposition often tells as much as one needs to know about it.

**Proposition 2.5** In Example 2.4.3, if $w : \pi \to \mathbb{Z}/2$ is surjective, the natural map

$$
\mathcal{N}_*(B\pi \downarrow \mathbb{RP}^\infty) \to \mathcal{N}_*(B\pi)
$$

is injective, at least on classes in dimension $* \geq 4$ represented by disjoint unions of connected manifolds $M_i$ with non-trivial $w_1$ and with each $u_i : M_i \to B\pi$ an isomorphism on $\pi_1$. 
Proof. Consider a class in $\mathcal{R}_n(B\pi \downarrow \mathbb{R}P^\infty)$ represented by $\bigsqcup_i M^n_i$, $n \geq 4$, with $u_i : M^n_i \to B\pi$ the classifying map for the universal cover, and suppose the first Stiefel-Whitney class of $M_i$ is $w \circ u_i$ and is non-trivial. Assume $\bigsqcup_i M^n_i$ bounds in $\mathcal{R}_n(B\pi)$. That means we have a manifold $W^{n+1}$ with $\partial W^{n+1} = \bigsqcup_i M^n_i$ and with a map $f : W \to B\pi$ extending each $u_i$. We may assume $W$ is connected.

Then $f^\#$ (the induced map on fundamental groups) is a split surjection, with splitting map $\pi \sim \pi_1(M_i) \xrightarrow{\iota_i} \pi_1(W)$, where $\iota_i : M_i \hookrightarrow W$. Since the first Stiefel-Whitney class for $W$ must extend $w \circ u_i$, it is trivial on $\ker f^\#$. Thus we may do surgery on embedded circles in the interior of $W$ and in the kernel of $f^\#$ to reduce to the case where $f^\#$ is also an isomorphism on $\pi_1$. (The assumption of dimension $* \geq 4$ makes it possible to kill $\ker f^\#$ completely with such surgeries.) Then the first Stiefel-Whitney class of $W$ must be represented by $w \circ f$, and we obtain a map $W \to B\pi$ extending $M \to B\pi$, showing that $\bigsqcup_i (M_i, u_i)$ bounds in $\mathcal{R}_n(B\pi \downarrow \mathbb{R}P^\infty)$. □

The simply connected cases of the positive scalar curvature analogue of the following theorem were proved in [6]; the general case of the positive scalar curvature analogue, with this formulation, is in [21] and [22].

**Theorem 2.6 (Bordism Theorem)** Let $M^n$ be a connected $B$-manifold with $n = \dim M \geq 5$, and assume that the map $M \to B$ is a 2-equivalence. Then $Y(M) \geq 0$ if and only if the $B$-bordism class of $M$ lies in the subgroup of $\Omega_n^B$ generated by $B$-manifolds with nonnegative Yamabe invariant.

**Sketch of Proof.** Let $N$ be a $B$-manifold $B$-bordant to $M$. The hypotheses combine (via the method of proof of the $\kappa$-Cobordism Theorem) to show that $M$ can be obtained from $N$ by surgeries in codimension $\geq 3$. Then if each component of $N$ has nonnegative Yamabe invariant, one can apply Theorem 2.2 to conclude that the same is true for $M$. This does it since addition in $\Omega_n^B$ comes from connected sum and additive inverses correspond to reversal of orientation, etc., which doesn’t affect the Yamabe invariant of the underlying manifold. □

Fortunately for applications, one can do better than this. For simplicity, we restrict attention to the three cases discussed in Examples 2.4.

**Theorem 2.7 (Jung, Stolz)** Let $M^n$ be a compact connected manifold with $n = \dim M \geq 5$.

1. If, as in Example 2.4.1, $M$ is spin with fundamental group $\pi$, then $Y(M) \geq 0$ if and only the class of $M \to B\pi$ in $\mathcal{K}_\pi(B\pi)$ lies in the subgroup $\mathcal{K}_\pi^\circ(B\pi)$ generated by classes of $M' \to B\pi$ with $M'$ a spin manifold with nonnegative Yamabe invariant, and $M' \to B\pi$ a map (not necessarily an isomorphism on $\pi_1$). Here $\mathcal{K}_\pi$ is the homology theory corresponding to the connective real $K$-theory spectrum.

2. If, as in Example 2.4.2, $M$ is oriented with fundamental group $\pi$, and the universal cover of $M$ is not spin, then $Y(M) \geq 0$ if and only the class
of $M \rightarrow B\pi$ in $H_n(B\pi, \mathbb{Z})$ lies in the subgroup $H^0_n(B\pi, \mathbb{Z})$ generated by classes of $M' \rightarrow B\pi$ with $M'$ an oriented manifold with nonnegative Yamabe invariant, and $M' \rightarrow B\pi$ a map (not necessarily an isomorphism on $\pi_1$).

3. If, as in Example 2.4.3, $M$ is non-orientable with fundamental group $\pi$, and if the universal cover of $M$ is not spin, then $Y(M) \geq 0$ if and only if the class of $M \rightarrow B\pi$ in $H_n(B\pi, \mathbb{Z}/2)$ lies in the subgroup $H^0_n(B\pi, \mathbb{Z}/2)$ generated by classes of $M' \rightarrow B\pi$ with $M'$ a manifold with nonnegative Yamabe invariant, and $M' \rightarrow B\pi$ a map.

Sketch of Proof. It was proved by Jung and Stolz (see [21] and [22]) that the kernel of the map $\Omega^\text{Spin}_n(B\pi) \rightarrow ko_n(B\pi)$ in case 1, and the kernel of the map $\Omega_n(B\pi) \rightarrow H_n(B\pi, \mathbb{Z})$ in case 2, are represented by manifolds with positive scalar curvature. Thus the result immediately follows from Theorem 2.6. Now consider Case 3. The “only if” direction is obvious, so suppose we are given $M$ non-orientable with fundamental group $\pi$ and universal cover non-spin, and assume the class of $M \rightarrow B\pi$ in $H_n(B\pi, \mathbb{Z}/2)$ lies in the subgroup $H^0_n(B\pi, \mathbb{Z}/2)$. By Theorem 2.6 and Example 2.4.3, it suffices to show that the class of $M$ in $\mathcal{R}_n(B\pi \downarrow \mathbb{R}P^\infty)$ lies in $\mathcal{R}_n^0(B\pi \downarrow \mathbb{R}P^\infty)$. By Proposition 2.5, $\mathcal{R}_n(B\pi \downarrow \mathbb{R}P^\infty)$ is detected by its image in $\mathcal{R}_n(B\pi)$. Since the unoriented bordism spectrum is an Eilenberg-Mac Lane spectrum,

$$\mathcal{R}_n(B\pi) \cong \bigoplus_{i+j=n} H_i(B\pi, \mathbb{Z}/2) \otimes \mathbb{Z}/2 \mathfrak{R}_j,$$

and each class in $\mathcal{R}_n(B\pi)$ is a sum of classes of the form $(M_1 \rightarrow B\pi) \times M_2$, where $M_2$ represents a class in $\mathfrak{R}_j$. Here the summand with $j = 0$ corresponds to the image of $M \rightarrow B\pi$ in $H_n(B\pi, \mathbb{Z}/2)$. We claim every class in $\mathfrak{R}_j$, $j > 0$, is represented by a manifold with nonnegative Yamabe invariant. Indeed, multiplicative generators of $\mathfrak{R}_j$ can be taken to be real projective spaces and quadric hypersurfaces in products of real projective spaces ([23], p. 97). All of these manifolds admit metrics of positive scalar curvature (cf. the argument in the proof of [1], Corollary C), except for a point in dimension $j = 0$. So by Theorem 2.6 above and Proposition 2.2 below, if the class of $M \rightarrow B\pi$ lies in $H^0_n(B\pi, \mathbb{Z}/2)$, then the class of $M \rightarrow B\pi$ in $\mathcal{R}_n(B\pi)$ is represented by a map $M' \rightarrow B\pi$, with $M'$ a manifold with nonnegative Yamabe invariant. Choose a bordism $f: W \rightarrow B\pi$ between $M \rightarrow B\pi$ and $M' \rightarrow B\pi$. As in the proof of Proposition 2.3, we may assume (by doing surgeries on the interior of $W$) that $f_\#$ is an isomorphism on $\pi_1$. As in the proof of Proposition 2.3, this implies $M'$ and $M$ represent the same element of $\mathcal{R}_n(B\pi \downarrow \mathbb{R}P^\infty)$, and we conclude using Theorem 2.6. □

This is now enough machinery to deal with “easy” torsion-free fundamental groups:

**Theorem 2.8** Let $M^n$ be a closed connected $n$-manifold with a fundamental group $\pi$ which is either free abelian or of homological dimension $\leq 4$. (This
The non-simply connected Yamabe invariant

includes the fundamental groups of aspherical 2-manifolds, 3-manifolds, and 4-manifolds.) Assume either that $M$ is spin or that its universal cover is non-spin. In the spin case, also assume that the Atiyah-Hirzebruch spectral sequence $H_p(B\pi, ko_q) \Rightarrow ko_* (B\pi)$ collapses. (This is automatic if $\pi$ is of homological dimension $\leq 3$.) Then if $n \geq 5$, $M$ has nonnegative Yamabe invariant.

**Proof.** By Theorem 2.7 it’s enough to show that for each of these groups $\pi$, $H^2_n (B\pi, \mathbb{Z})$ exhausts $H_n (B\pi, \mathbb{Z})$ and $ko^2_n (B\pi)$ exhausts $ko_n (B\pi)$ for $n \geq 5$. The non-spin case is easy, since for $\pi$ free abelian and any $n$, $H_n (B\pi, \mathbb{Z})$ is generated additively by the classes of tori, which carry flat metrics and thus have Yamabe invariant zero, whereas if $\pi$ has homological dimension $\leq 4$, $H_n (B\pi, \mathbb{Z})$ vanishes for $n \geq 5$. So consider the spin case. When $\pi$ is free abelian, the Atiyah-Hirzebruch spectral sequence collapses and

$$ko_n (B\pi) \cong \bigoplus_{p+q=n} H_p (B\pi, \mathbb{Z}) \otimes ko_q.$$ 

Thus this group is generated by the classes of $f : T^p \times N^q \to B\pi$, where the map $f$ factors through $T^p$. Since, as pointed out in [17], $ko_n$ is generated by the classes of manifolds of nonnegative Yamabe invariant, we have the desired result. The other cases are similar but easier. □

Most of this paper will now deal with the opposite extreme, the case where $\pi_1 (M)$ is finite. In this case, the following results reduce us to the case where the fundamental group is a $p$-group.

**Lemma 2.9** Suppose $M^n$ is a closed connected manifold with $Y(M) \geq 0$, and suppose $\tilde{M}$ is a finite covering of $M$. Then $Y(\tilde{M}) \geq 0$.

**Proof.** Let $m$ be the number of sheets of the covering $\tilde{M} \to M$. By assumption, given $\varepsilon > 0$, we can choose a conformal class $C$ on $M$ with $Y(M, C) \geq -\varepsilon$. That means there is a metric $g$ on $M$ with unit volume and constant scalar curvature $s \geq -\varepsilon$. Lift the metric $g$ up to $\tilde{M}$. That gives a metric on $\tilde{M}$ with volume $m$ and scalar curvature $s \geq -\varepsilon$. Rescaling, we get a metric on $\tilde{M}$ with unit volume and scalar curvature $s \geq -m^{-\frac{2}{n}} \varepsilon$. This being true for all $\varepsilon > 0$, it follows that $Y(\tilde{M}) \geq 0$. □

**Proposition 2.10** If $\pi_1$ and $\pi_2$ are groups and if $\varphi : \pi_1 \to \pi_2$ is a group homomorphism, then $\varphi$ sends $H^2_n (B\pi_1, \mathbb{Z})$ to $H^2_n (B\pi_2, \mathbb{Z})$, $H^2_n (B\pi_1, Z/2)$ to $H^2_n (B\pi_2, Z/2)$, and $ko^2_n (B\pi_1)$ to $ko^2_n (B\pi_2)$. If $\pi_1$ is a subgroup of $\pi_2$ of finite index, then the transfer map on $H_n$ or $ko_n$ sends $H^2_n (B\pi_2, \mathbb{Z})$ to $H^2_n (B\pi_1, \mathbb{Z})$, $H^2_n (B\pi_2, Z/2)$ to $H^2_n (B\pi_1, Z/2)$, and $ko^2_n (B\pi_2)$ to $ko^2_n (B\pi_1)$.

**Proof.** The first statement is obvious from the definitions in Theorem 2.7. The second statement follows from Lemma 2.9, since the transfer is realized geometrically via coverings. □
Theorem 2.11 (Kwasik, Schultz [9]) Let $M$ be a closed connected $n$-manifold with finite fundamental group $\pi$. Assume either that $M$ is spin or that its universal cover is non-spin. For each prime $p$, let $i_p: \pi_p \hookrightarrow \pi$ be the inclusion of a Sylow $p$-subgroup of $\pi$, and let $t_p: H_n(B\pi, \mathbb{Z}) \to H_n(B\pi_p, \mathbb{Z}),$ $t_p: H_n(B\pi, \mathbb{Z}/2) \to H_n(B\pi_p, \mathbb{Z}/2), t_p: ko_n(B\pi) \to ko_n(B\pi_p)$ be the transfer maps. Then $M$ has nonnegative Yamabe invariant if and only if $t_p([M])$ lies in the subgroup $H_n^0(B\pi_p, \mathbb{Z})$ in the oriented non-spin case, or in $ko_n^0(B\pi)$ in the spin case, for each $p$ dividing the order of $\pi$. In the non-orientable non-spin case, $M$ has nonnegative Yamabe invariant if and only if $t_2([M])$ lies in $H_n^0(B\pi_2, \mathbb{Z}/2)$.

Proof. The proof is almost word-for-word as in [9], but we review the argument. The “only if” statement is contained in Proposition 2.10. As for the “if” statement, let $A = \tilde{H}_n(B\pi, \mathbb{Z}), \tilde{H}_n(B\pi, \mathbb{Z}/2), \text{ or } ko_n(B\pi)$, and let $B$ be the subgroup $\tilde{H}_n^0(B\pi, \mathbb{Z}), \tilde{H}_n^0(B\pi, \mathbb{Z}/2), \text{ or } ko_n^0(B\pi)$. Similarly let $A_p = \tilde{H}_n(B\pi_p, \mathbb{Z}), \tilde{H}_n(B\pi_p, \mathbb{Z}/2), \text{ or } ko_n(B\pi_p)$, and let $B_p$ be the subgroup $\tilde{H}_n^0(B\pi_p, \mathbb{Z}), \tilde{H}_n^0(B\pi_p, \mathbb{Z}/2), \text{ or } ko_n^0(B\pi_p)$ (We can work with reduced homology since $H_\ast(pt) = H_\ast^0(pt)$ and $ko_\ast(pt) = ko_\ast^0(pt)$.)

Note that $A$ is a finite group and $B$ is a subgroup; we are trying to show that an element $[M]$ of $A$ lies in $B$ if $t_p([M]) \in B_p$ for all $p$. Now $\alpha_p = i_p \circ t_p$ is an endomorphism of $A$ which is an isomorphism on $A_p$, since $[\pi : \pi_p]$ is a unit modulo $p$. If $t_p([M]) \in B_p$ for all $p$, then $\alpha_p([M]) \in i_p(B_p) \subseteq B$ for all $p$, by Proposition 2.10. So that means the image of $[M]$ in $A_p$ lies in $B_p$ for all $p$, and thus $[M]$ lies in $B$. Note, incidentally, that in the non-orientable, non-spin case, only the Sylow 2-subgroup matters, since $\tilde{H}_\ast(B\pi_p, \mathbb{Z}/2) = 0$ for $p \neq 2$. □

Theorem 2.12 (Kwasik, Schultz [9]) Let $\pi$ be a finite group, and let
\[
e: \Omega^\infty\Sigma^\infty B\pi_+ \to \Omega^\infty\Sigma^\infty B\pi_+
\]
be an idempotent in the stable homotopy category (giving a stable splitting of $B\pi$). Then $\epsilon$ maps $H_n^0(\pi, \mathbb{Z}), H_n^0(\pi, \mathbb{Z}/2), \text{ and } ko_n^0(\pi)$ into themselves.

Sketch of Proof. As pointed out in [9], the proof of the Segal Conjecture implies that the stable splittings of $B\pi$ are essentially linear combinations of products of transfer maps and maps induced by group homomorphisms, so the result then follows from Proposition 2.10. □

3 Analytic Tools

In this section we present a number of analytic results that can be used to study the classes of manifolds with positive scalar curvature or with nonnegative Yamabe invariant. First we need a basic characterization of manifolds in the latter class.
Proposition 3.1 Let $M^n$ be a closed $n$-manifold. Then:

(i) If $M$ does not admit a metric of positive scalar curvature, then

$$Y(M) = -\inf_g \left( \int_M |s_g|^\frac{n}{2n} \, d\text{vol}_g \right)^\frac{2}{n}.$$  \hspace{1cm} (3.1)

Here the infimum is taken over all Riemannian metric $g$ on $M$, and $s_g$ denotes the scalar curvature of $g$.

(ii) Suppose that for each $\varepsilon > 0$, there exists a metric $g$ on $M$ with volume 1 and $|s_g| < \varepsilon$. Then $Y(M) \geq 0$. The converse is true if $n \geq 3$ or if $Y(M) = 0$.

Proof. Statement (i) is Proposition 1 in [13]. As for (ii), suppose the condition is satisfied. If $Y(M) > 0$, then we have nothing to prove, and if not, (i) shows that $Y(M) \geq 0$. In the converse direction, suppose $Y(M) \geq 0$. If $n \geq 3$ and if $Y(M) > 0$, then by a theorem of Kazdan and Warner [10], $M$ admits a metric $g$ with $s_g \equiv 0$, and obviously we may rescale $g$ to have volume 1 without changing this condition. If, on the other hand, $Y(M) = 0$, that means, by definition of the Yamabe invariant (recall equation (1.1)), that for all $\varepsilon > 0$, there exists a metric $g$ on $M$ with volume 1 and $s_g \leq 0$ constant and $> -\varepsilon$. So again the condition of (ii) is satisfied. □

Another basic fact is the following:

Proposition 3.2 Suppose $M^m$ and $N^n$ are closed manifolds, $n = \dim N \geq 1$, and also $Y(N) \geq 0$. Then $Y(M \times N) \geq 0$.

Proof. If $Y(N) > 0$, then $N$ admits a metric of positive scalar curvature and so does $M \times N$, so $Y(M \times N) > 0$. If $Y(N) = 0$, then by Proposition 3.1, given $\varepsilon > 0$, there exists a metric $g_\varepsilon$ on $N$ with volume 1 and $|s_{g_\varepsilon}| < \varepsilon$. Choose any metric $g'$ on $M$ with volume 1. If we give $M \times N$ the product metric $tg' \times g_\varepsilon$ (where $tg'$ means $g'$ rescaled by multiplying all distances by $t$), then this product metric has scalar curvature $t^{-2}s_{g'} + s_{g_\varepsilon}$ and volume $tm$. So the integral in (3.1) (with $M \times N$ in place of $M$) is

$$\iint |t^{-2}s_{g'} + s_{g_\varepsilon}|^\frac{n+m}{2n} \, d\text{vol}_{tg'} \, d\text{vol}_{g_\varepsilon} \leq t^n |Ct^{-2} + \varepsilon|^\frac{n+m}{2},$$  \hspace{1cm} (3.2)

for some constant $C$ (the maximum of $|s_{g'}|$ over $M$) independent of $t$ and $\varepsilon$. So the idea is to take $t$ large, and then given $t$, to take $\varepsilon$ of order $t^{-2}$. In equation (3.2), we see that the integral on the left-hand side is bounded by a constant times

$$t^n \left( t^{-2} \right)^{\frac{n+m}{2}} = t^{-n},$$

which goes to zero as $t \to \infty$. Thus by Proposition 3.1, the result follows. □

Next, we discuss the extension of the minimal hypersurface technique of [24] to the study of nonnegative Yamabe invariant. Suppose $M^n$ is a closed manifold.
with metric $g$, and suppose $H^{n-1}$ is a stable minimal hypersurface in $M$. In [24], it was shown that if $s_g > 0$, then $Y(H, [\bar{g}]) > 0$, where $\bar{g}$ denotes the induced metric on $H$ and $[\bar{g}]$ is its conformal class. In particular, there is a metric in $[\bar{g}]$ with positive scalar curvature, and this can be used to rule out positive scalar curvature metrics on many non-simply connected manifolds. Now it is not true that just because $Y(M) \geq 0$, then $Y(H) \geq 0$, since by Proposition 3.2, we can get a counterexample by taking $M = H \times S^1$ and $Y(H) < 0$ (say with $n-1 = 2$ or 4). However, the same estimates used in the proof of Theorem in [24] show that if $s_g \geq K$, where $K$ is a constant, then because the second variation of the $(n-1)$-dimensional volume of $H$ is positive, one has
\[ \int_H \frac{(\bar{s} - K)\phi^2}{2} + \int_H |\nabla \phi|^2 > 0 \] (3.3)
for all functions $\phi \in C^\infty(H)$ not vanishing identically. (Here $\bar{s}$, the scalar curvature of $H$, and $\nabla$ are to be computed with respect to the induced metric $\bar{g}$.) Assume $n > 3$ and consider the “conformal Laplacian”
\[ L_H = \frac{4(n-2)}{n-3} \Delta_H + \bar{s} \]
of $H$, where $\Delta_H$ is the usual (non-negative) Laplacian. (Recall that the dimension of $H$ is $n-1$, not $n$.) Then for $\phi$ as above we have
\[ \frac{1}{2} \langle L_H \phi, \phi \rangle = \frac{2(n-2)}{n-3} \int_H |\nabla \phi|^2 + \int_H \frac{\bar{s} \phi^2}{2} \]
\[ = \frac{n-1}{n-3} \int_H |\nabla \phi|^2 + \left( \int_H \frac{(\bar{s} - K)\phi^2}{2} + \int_H |\nabla \phi|^2 \right) + \frac{K}{2} \int_H \phi^2 \]
\[ > \frac{K}{2} \int_H \phi^2. \] (3.4)
Note the use of equation (3.3) at the last step. This implies that if $K$ is close to 0, then the conformal Laplacian $L_H$ is not too negative, and thus $Y(H, \bar{g})$ is not too negative, provided that the $(n-1)$-dimensional volume of $H$ is not too large.

If $n = 3$, things are even easier: we instead take $\phi \equiv 1$ in equation (3.3) and apply Gauss-Bonnet. These arguments thus prove the following two results:

**Theorem 3.3** Let $M^n$ be a closed manifold with metric $g$, and suppose $H^{n-1}$ is a stable minimal hypersurface in $M$. Also suppose that the metric $g$ is scalar-flat. Then $Y(H) \geq 0$.

**Proof.** Immediate from the above estimates. □

**Theorem 3.4** Let $M^2$ be a closed oriented surface of genus $g > 1$, and let $N^3 = S^1 \times M^2$. Then $Y(N) = 0$ by Proposition 3.2. (It cannot be strictly positive, by [7], Theorem 8.1, for example.) Thus there is a sequence $g_i$ of
metrics on $N^3$ with volume 1 and constant scalar curvatures $s_i$, with the scalar curvatures tending to 0 as $i \to \infty$. On the other hand, for any such sequence of metrics, diam$(N, g_i) \to \infty$.

\textbf{Proof}. Choose the metrics $g_i$ as in the statement of the theorem. Choose minimal submanifolds $M_i$ which are absolutely area-minimizing in the homology class $[M^2] \in H_2(S^1 \times M^2, \mathbb{Z})$ for the metric $g_i$. By inequality (3.3) with $\phi \equiv 1$,

$$
\lim_{i \to \infty} \int_{M_i} (\bar{s}_i - s_i) dvol_{\bar{g}_i} \geq 0.
$$

(3.5)

On the other hand, each $M_i$ must tend to $\infty$ as $i \to \infty$, since it represents a non-trivial homology class in the infinite cyclic cover $\mathbb{R} \times M^2$, while each mapping of a sphere into this space factors through a circle (since each abelian subgroup of $\pi_1(M)$ is cyclic) and is thus trivial in $\pi_2$. So by Gauss-Bonnet, $\int_{M_i} \bar{s}_i dvol_{\bar{g}_i} \leq -4\pi$. Comparing this with equation (3.3), we see the area of $\bar{M}_i$ with respect to $\bar{g}_i$ must tend to $\infty$ as $i \to \infty$, while the average value of $\bar{s}_i$ must go to 0, and in particular, diam$(\bar{M}_i, \bar{g}_i) \to \infty$. This in turn means diam$g_i \to \infty$, since otherwise we could choose representatives for the homology class $[M]$ in $(N, g_i)$ with bounded diameters, a contradiction. □

The next two results are the most significant in this paper; they will be used in the next section to deal with \textquotedblleft Toda brackets,\textquotedblright among the most intractable of bordism classes.

\textbf{Theorem 3.5} Let $M_0$ and $M_1$ be closed manifolds, not necessarily connected, that admit metrics of positive scalar curvature. Suppose $M_0 = \partial W_0$ and $M_1 = \partial W_1$ for some compact manifolds with boundary, $W_0$ and $W_1$. Form a new manifold

$$
M = (W_0 \times M_1) \cup_{M_0 \times M_1} (M_0 \times W_1)
$$

of dimension $n_0 + n_1 + 1$, where $n_0$ and $n_1$ are the dimensions of $M_0$ and $M_1$. Then $M$ admits a metric of positive scalar curvature.

\textbf{Proof}. We start by choosing metrics of positive scalar curvature, $g_0$ and $g_1$, on $M_0$ and $M_1$, respectively. Extend them to metrics $\bar{g}_0$ and $\bar{g}_1$ on $W_0$ and $W_1$, which are product metrics in neighborhoods of the boundaries. The trick is to write $M$ as a union of four pieces (not two) as follows:

$$
M = (W_0 \times M_1) \cup_{M_0 \times M_1} (T_0 \times M_1) \cup_{M_0 \times M_1} (M_0 \times T_1) \cup_{M_0 \times M_1} (M_0 \times W_1),
$$

where the \textquotedblleft tubes\textquotedblright $T_0$ and $T_1$ are (as smooth manifolds) $M_0 \times I$ and $M_1 \times I$, respectively. Call the pieces here $A_0$, $T_0 \times M_1$, $M_0 \times T_1$, and $A_1$ in that order. Since $g_0$ and $g_1$ have positive scalar curvature, we can choose (very small) constants $t_0 > 0$ and $t_1 > 0$ so that the metric $\bar{g}_0 \times t_1 g_1$ on $A_0$ and the metric $t_0 g_0 \times \bar{g}_1$ on $A_1$ have positive scalar curvature. Now all we have to do is
choose the metric $g_{T_0}$ on $T_0$ to interpolate between $t_0 g_0$ and $g_0$ and the metric $g_{T_1}$ on $T_1$ to interpolate between $t_1 g_1$ and $g_1$. If the tubes $T_0$ and $T_1$ are "very long," it is possible to do this so that $T_0$ and $T_1$ have positive scalar curvature, by the "Isotopy implies concordance" theorem. \[1\] Lemma 3. (In fact, in this case, one can write down an explicit warped product metric that does the trick.) Then all the metrics fit together to give a metric of positive scalar curvature on $M$. \[2\]

The next theorem is quite similar, but considerably more delicate.

**Theorem 3.6** Let $M_0$ and $M_1$ be closed manifolds, not necessarily connected, each with nonnegative Yamabe invariant. (When $M_i$ is disconnected, we mean that each component is required to have nonnegative Yamabe invariant.) Suppose $M_0 = \partial W_0$ and $M_1 = \partial W_1$ for some compact manifolds with boundary, $W_0$ and $W_1$. Form a new manifold

$$M = (W_0 \times M_1) \cup_{M_0 \times M_1} (M_0 \times W_1)$$

of dimension $n_0 + n_1 + 1$, where $n_0$ and $n_1$ are the dimensions of $M_0$ and $M_1$. Then, excluding the case where $Y(M_0) = 0$, $n_1 = 2$, and $Y(M_1) > 0$, it follows that $Y(M) > 0$.

**Proof.** We follow the same approach as in the proof of Theorem 3.5. If $Y(M_0)$ and $Y(M_1)$ are both strictly positive, we’re done by Theorem 3.5, so we may assume at least one of $M_0$ and $M_1$ has $Y = 0$. Then we’re excluding the case where the other manifold is a disjoint union of copies of $S^2$ or $\mathbb{RP}^2$, so by Proposition 3.1, we may assume both manifolds have metrics of unit volume which are almost scalar-flat. By Proposition 3.1, it is enough to show that $M$ has a metric for which the integral in $[3.7]$ is as small as one likes. We will estimate the integral separately over the four pieces of $M$ (as in the last proof) and add the results. Fix $\varepsilon > 0$ and choose metric $g_0$ and $g_1$ on $M_0$ and $M_1$, respectively, each with volume 1 and with small constant scalar curvatures, $s_0$ and $s_1$, respectively, with $|s_0|, |s_1| < \varepsilon$. Extend $g_0$ and $g_1$ to metrics $\tilde{g}_0$ and $\tilde{g}_1$ on $W_0$ and $W_1$, which are product metrics in neighborhoods of the boundaries. Then the scalar curvature of the metric $\tilde{g}_0 \times t_1 g_1$ on $A_0$ is $s_{\tilde{g}_0} + t_1^{-2} s_1$ and the scalar curvature of the metric $t_0 g_0 \times \tilde{g}_1$ on $A_1$ is $s_{\tilde{g}_1} + t_0^{-2} s_0$. (The constants $t_0$ and $t_1$ will be chosen later.) Furthermore, the volumes of these metrics are\[vol(\tilde{g}_0) \times t_1^{n_1}\] for $A_0$ and\[vol(\tilde{g}_1) \times t_0^{n_0}\] for $A_1$. Letting $t_0$ and $t_1$ go to 0, we see there are constants $c_0 > 0$ and $c_1 > 0$ with

$$\int_{A_0} \left| s_{\tilde{g}_0} + t_1^{-2} s_1 \right|^{n_0 + n_1 + 1} 2^{n_1} dvol_{\tilde{g}_0} dvol_{1, g_1} \leq c_0 t_1^{-(n_0 + n_1 + 1)} \varepsilon^{-n_0 + n_1 + 1} t_1^{n_1}, \tag{3.6}$$

$$\int_{A_1} \left| s_{\tilde{g}_1} + t_0^{-2} s_0 \right|^{n_0 + n_1 + 1} 2^{n_0} dvol_{t_0 g_0} dvol_{\tilde{g}_1} \leq c_1 t_0^{-(n_0 + n_1 + 1)} \varepsilon^{-n_0 + n_1 + 1} t_0^{n_0}. \tag{3.7}$$
The right-hand sides of (3.6) and (3.7) can be rewritten as

\[ c_0 t_1^{-(n_0+1)} \varepsilon^{\frac{n_0+n_1+1}{2}} = c_0 \varepsilon^{n_1/2} \left( \frac{\varepsilon}{t_1^2} \right)^{\frac{n_0+1}{2}} \]

and

\[ c_1 t_0^{-(n_1+1)} \varepsilon^{\frac{n_0+n_1+1}{2}} = c_1 \varepsilon^{n_0/2} \left( \frac{\varepsilon}{t_0^2} \right)^{\frac{n_1+1}{2}}, \]

respectively.

Next we need to deal with the tubes \( T_0 \) and \( T_1 \). We give these warped product metrics of the form \( f_i(x)g_i \times g_R \), \( i = 0, 1 \), where \( g_R \) is the standard metric on the line, and \( x \) is the parameter along the length of the tube. The function \( f_i \) will be chosen to interpolate between 0 and \( t_i \). If we write \( f_i = \exp(-u_i) \), we need to choose \( u_i \) as in the following picture, so that the graph has vanishing first and second derivatives at both ends:

Here \( l \), to be taken large, is the length of the tube. Since \( t_i < 1 \) and \( \text{vol}(g_i) = 1 \), the volume of \( T_i \) will be bounded by \( l \), as will the volume of \( T_0 \times M_1 \) or \( M_0 \times T_1 \), when we take the product with the metric \( g_1 \) on \( M_1 \) or \( g_0 \) on \( M_0 \). The scalar curvature of \( T_i \) is given by equation (7.35) on p. 157 of [7], which gives:

\[ \frac{1}{f_i^2} s_i - \frac{n_i(n_i-1)}{f_i^2} (f_i')^2 - 2n_i f_i f_i''. \]

Since \( f = \exp(-u_i) \), \( \frac{f'}{f_i} = -u_i' \) and \( \frac{f''}{f_i} = (u_i')^2 - u_i'' \). Now we can choose \( u_i \) so that \( u_i' \) is bounded by a constant times \( \frac{\log(1/t_i)}{t_i^2} \) and \( u_i'' \) is bounded by a constant times \( \frac{\log(1/t_i)}{t_i^2} \). Thus the scalar curvature of \( T_i \) is bounded in absolute value by

\[ \frac{\varepsilon}{t_i^2} + d_i \left( \frac{\log(1/t_i)}{t_i^2} \right)^2 \]
for some constant $d_i$. Thus the integrals over $T_0 \times M_1$ and $M_0 \times T_1$ give:

$$\int_{T_0 \times M_1} |s_{T_0} + s_1| \frac{t_0^{n_0+n_1+1}}{2} \, d\text{vol}_{T_0} \, d\text{vol}_{g_1} \leq |l| \left( \epsilon + \frac{\epsilon}{t_0^2} + d_0 \frac{(\log(1/t_0))^2}{l^2} \right)^{\frac{n_0+n_1+1}{2}}$$

(3.8)

$$\int_{M_0 \times T_1} |s_{g_0} + s_{T_1}| \frac{t_1^{n_0+n_1+1}}{2} \, d\text{vol}_{g_0} \, d\text{vol}_{T_1} \leq |l| \left( \epsilon + \frac{\epsilon}{t_1^2} + d_1 \frac{(\log(1/t_1))^2}{l^2} \right)^{\frac{n_0+n_1+1}{2}}.$$  

(3.9)

Now all we have to do is choose the parameters $t_0$, $\epsilon$, and $l$ to make all of (3.6), (3.7), (3.8), and (3.9) simultaneously small. We do this as follows. First choose $t_0$ and $t_1$ very small. Then choose $l$ large enough so that the terms

$$l \left( \frac{(\log(1/t_i))^2}{l^2} \right)^{\frac{n_0+n_1+1}{2}} = \frac{(\log(1/t_i))^{n_0+n_1+1}}{ln_0+n_1}$$

are small. Then finally choose $\epsilon/t_i^2$ extremely small so that

$$l \left( \frac{\epsilon}{t_i^2} \right)^{\frac{n_0+n_1+1}{2}}$$

is also small. That does it. □

4 Applications to Non-Negativity of the Yamabe Invariant

We’re now ready for the first main results of this paper.

Theorem 4.1 Let $M^n$ be a closed, connected, $n$-manifold with abelian fundamental group, with non-spin universal cover, and with $n \geq 5$. Then $M$ has nonnegative Yamabe invariant.

Proof. Consider the oriented case. (The non-orientable case works exactly the same way, but with integral homology replaced by homology with coefficients in $\mathbb{Z}/2$.) By Theorem 2.7, it’s enough to show that $H_2^0(B\pi_1(M), \mathbb{Z})$ exhausts the image in $H_*(B\pi_1(M), \mathbb{Z})$ of $\Omega_*(B\pi_1(M))$. Write $\pi_1(M)$ as $\mathbb{Z}^k \times \pi$, with $\pi$ finite abelian. Since the homology of a free abelian group is torsion free, the Künneth Theorem gives

$$H_n(B\pi_1(M), \mathbb{Z}) \cong \bigoplus_{p+q=n} H_p(B\mathbb{Z}^k, \mathbb{Z}) \otimes H_q(B\pi, \mathbb{Z}),$$

where $p+q=n$. Therefore $H_2^0(B\pi_1(M), \mathbb{Z})$ exhausts the image in $H_2(B\pi_1(M), \mathbb{Z})$ of $\Omega_2(B\pi_1(M))$ for $n \geq 5$. □
and so the homology of $B\pi_1(M)$ is generated by classes of products of tori with homology classes of $B\pi$. So by Proposition 5.2, we only have to show that $H^2_{\ast}(\mathbb{B},\mathbb{Z})$ exhausts the image in $H_\ast(\mathbb{B},\mathbb{Z})$ of $\Omega_\ast(\mathbb{B}_1(M))$. In other words, we are reduced to the case of finite abelian groups. By Theorem 2.11, we can further assume that $\pi_1(M)$ is a finite abelian $p$-group for some prime $p$ (and in the non-orientable case, we can further assume that $p = 2$). We will come back to finite abelian $p$-groups after a short digression. □

Lemma 4.2 Let $\pi$ be a cyclic group of prime power order $p^k$. Then each class in $H_n(\mathbb{B},\mathbb{Z})$ is represented by an oriented manifold with nonnegative Yamabe invariant, and if $n > 1$, by an oriented manifold with positive scalar curvature.

If $p = 2$, then also each class in $H_n(\mathbb{B},\mathbb{Z}/2)$ is represented by a manifold (not necessarily orientable) with nonnegative Yamabe invariant, and if $n > 1$, by a manifold with positive scalar curvature.

Proof. Note that $H_{2n+1}(\mathbb{B},\mathbb{Z})$ is cyclic of order $p^k$, with a generator represented by the lens space $S^{2n+1}/\pi \to \mathbb{B}$, and $H_{2n}(\mathbb{B},\mathbb{Z})$ vanishes for $n > 0$. Since the lens space has positive scalar curvature except in the exceptional case $n = 0$, when it has a flat metric, the first statement is immediate.

Now consider the case of $\mathbb{Z}/2$-homology and $p = 2$. Then $H_n(\mathbb{B},\mathbb{Z}/2)$ is cyclic of order 2 for all $n \geq 1$. When $k = 1$, things are again easy, as we have generators $\mathbb{RP}^n \to \mathbb{B}$ for all the homology groups, with positive scalar curvature except in the exceptional case $n = 1$. This leaves the case $k > 1$. In that case, $H^\ast(\mathbb{B},\mathbb{Z}/2) \cong \mathbb{F}_2[u,v]/(u^2)$, where $\mathbb{F}_2 = \mathbb{Z}/2$ is the field of two elements, $v \in H^1(\mathbb{B},\mathbb{F}_2)$ corresponds to the group homomorphism $\pi \to \mathbb{Z}/2$, and $u \in H^2(\mathbb{B},\mathbb{F}_2)$ is the class of the central extension

$$1 \to \langle a^{2^k} \mid a^{2^{k+1}} = 1 \rangle \to \langle a \mid a^{2^{k+1}} = 1 \rangle \to \langle a \mid a^{2^k} = 1 \rangle \to 1,$$

via the usual correspondence between $H^2$ and central extensions. Since the pull-back of this central extension to the unique two-element subgroup of $\pi$ is non-trivial, the inclusion $\iota : \mathbb{Z}/2 \hookrightarrow \pi$ induces an isomorphism

$$\iota^* : H^2(\mathbb{B},\mathbb{F}_2) \to H^2(\mathbb{Z}/2,\mathbb{F}_2),$$

and thus $\iota^* (u^n)$ is the generator of $H^{2n}(\mathbb{Z}/2,\mathbb{F}_2)$. By duality,

$$\iota_* : H_{2n}(\mathbb{Z}/2,\mathbb{F}_2) \to H_{2n}(\mathbb{B},\mathbb{F}_2)$$

is an isomorphism, and so the generator of $H_{2n}(\mathbb{B},\mathbb{F}_2)$ is represented by

$$\mathbb{RP}^{2n} \to \mathbb{Z}/2 \xrightarrow{\iota} \mathbb{B}, \quad n \geq 1.$$

We still need to find geometric generators for $H_{2n+1}(\mathbb{B},\mathbb{F}_2)$. Since $H^{2n+1}(\mathbb{B},\mathbb{F}_2)$ is generated by $u^n v$, and the cup product comes from restricting the exterior product $u^n \boxtimes v \in H^{2n+1}(\mathbb{B} \times \mathbb{B},\mathbb{F}_2)$ to the diagonal copy of $\mathbb{B}$, we see by duality that the generator of $H_{2n+1}(\mathbb{B},\mathbb{F}_2)$ is represented by $\Delta^*(\mathbb{RP}^{2n} \times S^1 \to \mathbb{B}).$
by a manifold of nonnegative Yamabe invariant. Since Tor is left exact and we may replace the positive scalar curvature or the nonnegative Yamabe invariant property by Proposition 2.10, the proof is complete.

**Proof of Theorem 4.1, continued.** Recall that we have already reduced to the case where the fundamental group \( \pi \) of \( M \) is a finite abelian \( p \)-group, hence a finite product of cyclic \( p \)-groups. In the non-orientable case, since \( H_*(B\pi, \mathbb{F}_2) \) is by the Künneth Theorem generated by products of homology classes for cyclic groups, and since all these homology classes are represented by manifolds of nonnegative Yamabe invariant by Lemma 4.2, we are done by Proposition 3.3.

In the orientable case, things are more complicated because we have to deal with the Tor terms in the Künneth Theorem, and also because the natural map (the Hurewicz homomorphism for MSO) \( \Omega_*(B\pi) \to H_*(B\pi, \mathbb{Z}) \) may not be surjective, and may not be split onto its image. Thus the argument will require some care. We prove the theorem by induction on the rank (the number of cyclic factors in a product decomposition) of \( \pi \). If the rank is 1, \( \pi \) is cyclic and we are done by Lemma 4.2. So assume the result is true for \( p \)-groups of smaller rank, and write \( \pi = \pi' \times \mathbb{Z}/p^k \), where we may assume that \( p^k \) is less than or equal to the order of every cyclic factor of \( \pi' \), and thus less than or equal to the order of every cyclic factor of the homology of \( B\pi' \). First assume that \( p = 2 \). This case is easier because MSO localized at 2 is a direct sum of Eilenberg-Mac Lane spectra (see [13] and [29], or [21] for a review of the literature), and thus \( H_*(B\pi, \mathbb{Z}) \) can be identified with a direct summand in \( \Omega_*(B\pi) \), and similarly for \( \pi' \). By inductive hypothesis, each cyclic factor (say of order \( p^s \), \( s \geq k \)) in \( H_j(B\pi', \mathbb{Z}) \) is generated by the class of a manifold \( M' \to B\pi' \), where \( M' \) has nonnegative Yamabe invariant. If \( n - j \) is odd, then we get a corresponding tensor term in the Künneth formula for the homology of \( B\pi \), and it is represented by a product of \( M' \) with either \( S^1 \) or a lens space, and so it is represented by a manifold with nonnegative Yamabe invariant. If \( n - j \geq 2 \) is even, there is a contribution to \( H_n(B\pi, \mathbb{Z}) \) of the form \( \text{Tor}_2(\mathbb{Z}/p^s, \mathbb{Z}/p^k) \), coming from \( H_j(B\pi', \mathbb{Z}) \) and \( H_{n-j-1}(B\mathbb{Z}/p^k, \mathbb{Z}) \), which we need to represent by a manifold of nonnegative Yamabe invariant. Since Tor is left exact and \( \text{Tor}_2(\mathbb{Z}/p^s, \mathbb{Z}/p^k) \) is cyclic of order \( p^k \), the map

\[
\text{Tor}_2(\mathbb{Z}/p^k, \mathbb{Z}/p^k) \to \text{Tor}_2(\mathbb{Z}/p^s, \mathbb{Z}/p^k)
\]

induced by the inclusion \( \mathbb{Z}/p^k \hookrightarrow \mathbb{Z}/p^s \) is an isomorphism, so without loss of generality, we may replace \( M' \) by something representing a multiple of its homology class, and assume \( s = k \). Choose \( M'' \to B\mathbb{Z}/p^k \), with \( M'' \) either \( S^1 \) or a lens space, of dimension \( n - j - 1 \), generating \( H_{n-j-1}(B\mathbb{Z}/p^k, \mathbb{Z}) \). We may assume the bordism classes of \( M' \to B\pi' \) and \( M'' \to B\mathbb{Z}/p^k \) both have order \( p^k \). Then their Tor product in the homology of \( B\pi \) may be represented by the cobordism Massey product \( \langle M', p^k, M'' \rangle \) (see [1]), or in other words, by a Toda bracket construction as in Theorem 3.3. More precisely, choose \( W_0 \) bounding \( p^k M' \) over \( B\pi' \) and \( W_1 \) bounding \( p^k M'' \) over \( B\mathbb{Z}/p^k \), and glue
Note that the map $\Omega^*Z$ in $\text{Tor}_{M}W$ together with $\gamma$ completes the inductive step. Now consider the case where $p$ is odd. In this case, it’s important to point out that the inductive hypothesis is simply that the image of $\Omega_*(B\pi') \to H_*(B\pi',\mathbb{Z})$ is represented by manifolds with nonnegative Yamabe invariant, as this map is not usually surjective. However, in this case we have one additional tool in our arsenal, namely Landweber’s Künneth Theorem for oriented bordism $[12]$. More precisely, we apply Theorem A of $[12]$, which applies since $\tilde{H}_*(B\mathbb{Z}/p^k,\mathbb{Z})$ consists entirely of odd torsion and the Atiyah-Hirzebruch spectral sequence $H_*(B\mathbb{Z}/p^k,\Omega_*) \Rightarrow \Omega_*(B\mathbb{Z}/p^k)$ collapses for dimensional reasons. ($\Omega_*$ localized at $p$ is free over $\mathbb{Z}(p)$ and concentrated in degrees divisible by 4, and $\tilde{H}_*(B\mathbb{Z}/p^k,\mathbb{Z}(p))$ is non-zero only in odd degrees.) Note also that the proof of Landweber’s Theorem shows that $\Omega_*(B\mathbb{Z}/p^k)(p)$ has homological dimension 1 over $\mathbb{Z}(pt)(p)$. Now observe that we have a commutative diagram with exact rows:

\[
\begin{array}{ccccccccc}
0 & \longrightarrow & \Omega_*(B\pi') \otimes_{\Omega_*} \Omega_*(B\mathbb{Z}/p^k) & \longrightarrow & \Omega_*(B\pi) & \longrightarrow & \text{Tor}_{\Omega_*} \left( \Omega_*(B\pi'), \Omega_*(B\mathbb{Z}/p^k) \right) & \longrightarrow & 0 \\
\downarrow & & & & \downarrow \alpha & & \downarrow \beta & & \downarrow \gamma & & 0 \\
0 & \longrightarrow & H_*(B\pi') \otimes_{\mathbb{Z}} H_*(B\mathbb{Z}/p^k) & \longrightarrow & H_*(B\pi) & \longrightarrow & \text{Tor}_\mathbb{Z} \left( H_*(B\pi'), H_*(B\mathbb{Z}/p^k) \right) & \longrightarrow & 0.
\end{array}
\]

(4.1)

in which the vertical arrows are induced by the natural transformation $\Omega_* \to H_*$. Note that the map $\Omega_*(B\mathbb{Z}/p^k) \to H_*(B\mathbb{Z}/p^k)$ is surjective, and denote the image of $\Omega_*(B\pi') \to H_*(B\pi')$ by $RH_*(B\pi')$ (for “representable homology”). The image of $\alpha$ is then obviously $RH_*(B\pi') \otimes_{\mathbb{Z}} H_*(B\mathbb{Z}/p^k)$; classes here are represented by products of manifolds of nonnegative Yamabe invariant (because of the inductive hypothesis), so these have nonnegative Yamabe invariant. The image of $\beta$ is by definition $RH_*(B\pi)$, whereas the image of $\gamma$ is evidently contained in $\text{Tor}_\mathbb{Z} \left( RH_*(B\pi'), H_*(B\mathbb{Z}/p^k) \right)$. Also $\gamma$ factors through

$$\text{Tor}_\mathbb{Z} \left( \Omega_*(B\pi'), \Omega_*(B\mathbb{Z}/p^k) \right).$$

But this latter group is generated by cobordism Massey products $\langle M', p^l, M'' \rangle$, where $M' \to B\pi'$ and $M'' \to B\mathbb{Z}/p^k$. By inductive hypothesis, $M'$ and $M''$ can be chosen to have nonnegative Yamabe invariant, hence so can this Toda bracket by Theorem $3.6$. Again, the exceptional case of that Theorem never arises in our context. So this shows that the image of $\gamma$ is represented by manifolds of nonnegative Yamabe invariant. Chasing diagram (4.1) now shows that $RH_*(B\pi)$ is represented by manifolds with nonnegative Yamabe invariant, which completes the inductive step for the case $p$ odd. \[\Box\]
Corollary 4.3 Let $M^n$ be a closed, connected, $n$-manifold with finite fundamental group $\pi$, with non-spin universal cover, and with $n \geq 5$. Also assume all Sylow subgroups of $\pi$ are abelian. Then $M$ has nonnegative Yamabe invariant.

Proof. This is immediate from Theorem 4.1 and Theorem 2.11. □

In the odd order case, we can carry this over to the spin case as well:

Theorem 4.4 Let $M^n$ be a closed, connected, spin $n$-manifold with finite fundamental group $\pi$ of odd order, and with $n \geq 5$. Also assume all Sylow subgroups of $\pi$ are abelian. Then $M$ has nonnegative Yamabe invariant.

Proof. By Petean’s theorem [17], this is true when $\pi$ is trivial. As before, it’s enough to consider the case of an abelian $p$-group, $p$ odd. But for $\pi$ of odd order, the natural map $\tilde{\Omega}^*_{\text{Spin}}(B\pi) \to \tilde{\Omega}^*_{\text{Spin}}(B\mathbb{Z}/p^k)$ is an isomorphism, since the map of spectra $M_{\text{Spin}} \to M_{\text{SO}}$ is an equivalence after localizing at $p$ (see [15]).

We prove the result by induction on the rank of $\pi$. Thus write $\pi = \pi' \times \mathbb{Z}/p^k$, and assume by inductive hypothesis that the theorem is true for $\pi'$. Since $\tilde{\Omega}^*_{\text{Spin}}(B\pi') \to \tilde{\Omega}^*_{\text{Spin}}(B\mathbb{Z}/p^k)$ and $\tilde{\Omega}^*_{\text{Spin}}(B\mathbb{Z}/p^k) \to \tilde{\Omega}^*_{\text{Spin}}(B\mathbb{Z}/p^k)$ are isomorphisms, we have by Landweber’s Theorem [12] an exact sequence

$$0 \to \Omega^*_{\text{Spin}}(B\pi') \otimes \Omega^*_{\text{Spin}}(B\mathbb{Z}/p^k) \to \Omega^*_{\text{Spin}}(B\pi) \to \text{Tor}_{\Omega^*_{\text{Spin}}}(\Omega^*_{\text{Spin}}(B\pi'), \Omega^*_{\text{Spin}}(B\mathbb{Z}/p^k)) \to 0. \quad (4.2)$$

By inductive hypothesis, each element of $\Omega^*_{\text{Spin}}(B\pi')$ is represented by a map $M' \to B\pi'$, with $M'$ a spin $s$-manifold with nonnegative Yamabe invariant, and similarly each element of $\Omega^*_{\text{Spin}}(B\mathbb{Z}/p^k)$ is represented by a map $M'' \to B\mathbb{Z}/p^k$, with $M''$ a spin $t$-manifold with nonnegative Yamabe invariant. Then $[M' \to B\pi'] \otimes [M'' \to B\mathbb{Z}/p^k]$ in the tensor term on the left side of (4.2) is represented by $M' \times M'' \to B\pi$, which has nonnegative Yamabe invariant. Furthermore, the Tor term $\text{Tor}_{\Omega^*_{\text{Spin}}}(\Omega^*_{\text{Spin}}(B\pi'), [M'' \to B\mathbb{Z}/p^k])$ on the right of (4.2) pulls back (non-canonically) to the class of a Toda bracket $\langle M', P, M'' \rangle$, where $P$ is some element from the coefficient ring $\Omega^*_{\text{Spin}}$. Since $M'$, $P$, and $M''$ all have nonnegative Yamabe invariant (we don’t even need to know anything about $P$!), it follows from Theorem 3.6 that this Toda bracket has nonnegative Yamabe invariant, and this completes the inductive step. □

5 Applications to Positive Scalar Curvature

It turns out that the method of proof of Theorem 4.1, if we replace Theorem 3.6 by Theorem 3.3, gives substantial results on the positive scalar curvature problem for manifolds with finite abelian fundamental group for which the universal cover is non-spin, since all of the homology generators constructed above have positive scalar curvature by Theorem 3.3, except for those involving Toda brackets and products of one-dimensional homology classes. We proceed to formalize this as follows:
Definition 5.1 Let $\pi$ be a finitely generated abelian group. Call a class in $H_n(B\pi, \mathbb{Z})$ or in $H_n(B\pi, \mathbb{Z}/2)$ toral if it is represented by a map $T^n \to B\pi$. Note that any such map is determined up to homotopy by the associated map $\mathbb{Z}^n \to \pi$ on fundamental groups, which we may assume without loss of generality to have image of rank $n \leq r$, where $r$ is the rank of $\pi$, that is, the minimal number of cyclic factors when we write $\pi$ as a direct sum of cyclic groups, so toral classes only exist in degrees $n \leq r$. Let $H_n^{\text{toral}}(B\pi, \mathbb{Z}) \subseteq H_n(B\pi, \mathbb{Z})$ be the subgroup generated by the the toral classes, and call this the toral subgroup.

Proposition 5.2 Let $\pi$ be an elementary abelian $p$-group of rank $r$, that is, $(\mathbb{Z}/p)^r$. Then for all $n \geq 1$, $H_n(B\pi, \mathbb{Z})$ is also elementary abelian, of rank equal to

$$\sum_{j=1}^{n} (-1)^{n-j} \binom{j+r-1}{r-1}.$$ 

The toral subgroup $H_n^{\text{toral}}(B\pi, \mathbb{Z})$ is a direct summand in $H_n(B\pi, \mathbb{Z})$, of rank the binomial coefficient $\binom{r}{n}$. (Note that this vanishes for $n > r$.)

Proof. The homology groups $H_n(B\mathbb{Z}/p, \mathbb{Z})$ vanish for $n > 0$ even and are $\mathbb{Z}/p$ for $n$ odd. So by iterated applications of the Künneth Theorem, all integral homology groups of $\pi$ (other than $H_0$, which is $\mathbb{Z}$), are elementary abelian $p$-groups. Consider the Poincaré series

$$P(r, t) = 1 + \sum_{n=1}^{\infty} t^n \dim_{\mathbb{Z}/p} H_n(B(\mathbb{Z}/p)^r, \mathbb{Z}).$$

Then

$$P(1, t) = 1 + t + t^3 + t^5 + \cdots = 1 + \frac{t}{1-t^2} = \frac{1+t-t^2}{1-t^2}. \quad (5.1)$$

The Künneth Theorem gives the recursion relation

$$P(r+1, t) = P(r, t)P(1, t) + t (P(r, t) - 1) (P(1, t) - 1), \quad (5.2)$$

where the first term comes from the “tensor terms” and the second term comes from the “Tor terms.” Putting together equations (5.1) and (5.2) yields by induction on $r$ the formula

$$P(r, t) = \frac{1 + t(1-t)^r}{(1-t)^r(1+t)} = \frac{t}{1+t} + \frac{1}{(1-t)^r(1+t)}.$$ 

For $n \geq 1$, the coefficient of $t^n$ in this expression is

$$(-1)^{n+1} + \sum_{j=0}^{n} (-1)^{n-j} \binom{j+r-1}{r-1},$$
which is the expression in the statement of the Proposition. On the other hand, the toral subgroup is generated just by the products of distinct generators of $H_1$, so in degree $n$, we have $\binom{r}{n}$ possibilities. □

Similarly (though more simply), we have:

**Proposition 5.3** Let $\pi$ be an elementary abelian $2$-group of rank $r$, that is, $(\mathbb{Z}/2)^r$. Then for all $n \geq 0$, $H_n(B\pi, \mathbb{Z}/2)$ is also elementary abelian, of rank equal to

$$\binom{n + r - 1}{r - 1}.$$

The toral subgroup $H_n^{\text{toral}}(B\pi, \mathbb{Z}/2)$ is a direct summand in $H_n(B\pi, \mathbb{Z}/2)$, of rank the binomial coefficient $\binom{r}{n}$. (Note that this vanishes for $n > r$.)

**Proof.** This is easier than the previous case since there are no Tor terms. The Poincaré series for $H_*(B\mathbb{Z}/2, \mathbb{Z}/2)$ is

$$\sum_{n=0}^{\infty} t^n = \frac{1}{1 - t},$$

and so the Poincaré series for $H_*(B\pi, \mathbb{Z}/2)$ is

$$\frac{1}{1 - t}^r = \sum_{n=0}^{\infty} \binom{n + r - 1}{r - 1} t^n,$$

which yields the desired formula. □

**Definition 5.4** Let $\pi$ be a finite abelian $p$-group, say $\prod_{i=1}^{r} \mathbb{Z}/p^{k_i}$. For purposes of this definition, $H_*$ means homology with $\mathbb{Z}$ coefficients if $p \neq 2$, and homology with $\mathbb{Z}/2$ coefficients if $p = 2$. We define a splitting $H_n(B\pi) = H_n^{\text{toral}}(B\pi) \oplus H_n^{\text{atoral}}(B\pi)$ inductively as follows. If $r = 1$, $H_n^{\text{toral}}(B\pi) = H_n(B\pi)$ if $n \leq 1$ and $H_n^{\text{toral}}(B\pi) = 0$ for $n \geq 2$, so we let $H_n^{\text{atoral}}(B\pi) = \bigoplus_{n \geq 2} H_n(B\pi)$. If $r > 1$, write $\pi = \pi' \times p^k$, $k = kr$, where $\pi' = \prod_{i=1}^{r-1} \mathbb{Z}/p^{k_i}$. Choose a splitting of the Künneth formula

$$0 \rightarrow H_*(B\pi') \otimes_{\mathbb{Z}^r} H_*(B\mathbb{Z}/p^k) \rightarrow H_*(B\pi) \xrightarrow{\epsilon} \text{Tor}_{\mathbb{Z}}(H_*(B\pi'), H_*(B\mathbb{Z}/p^k)) \rightarrow 0. \quad (5.3)$$

By induction, we have splittings $H_*(B\pi') = H_1^{\text{toral}}(B\pi') \oplus H_1^{\text{atoral}}(B\pi')$ and $H_*(B\mathbb{Z}/p^k) = H_1^{\text{toral}}(B\mathbb{Z}/p^k) \oplus H_1^{\text{atoral}}(B\mathbb{Z}/p^k)$. The atoral part of the tensor term on the left is defined to be

$$(H_*(B\pi') \otimes H_*^{\text{atoral}}(B\mathbb{Z}/p^k)) \oplus (H_*^{\text{atoral}}(B\pi') \otimes H_*^{\text{toral}}(B\mathbb{Z}/p^k)).$$

Then we define $H_*^{\text{atoral}}(B\pi)$ to be the direct sum of the atoral piece of the tensor term with the image of the Tor term under the splitting of the exact sequence (5.3).
Definition 5.5 For any space $X$, we denote by $RH_* (X)$ the image of the Hurewicz map $\Omega_* (X)$ in $H_* (X, \mathbb{Z})$, and call it the representable homology. (This already made an appearance in the proof of Theorem 4.1.) Note that $RH_*$ is a functor, though not a homology theory. By Lemma 5.2, $RH_* (B\pi) = H_* (B\pi, \mathbb{Z})$ when $\pi$ is a cyclic group.

The following fact, which is somewhat surprising, will be our key technical tool:

Proposition 5.6 Let $\pi$ be an elementary abelian $p$-group of rank 2, where $p$ is an odd prime. Then $RH_{\text{odd}} (B\pi)$ is generated (as an abelian group) by the images of $RH_* (B\sigma)$, as $\sigma$ runs over the cyclic subgroups of $\pi$.

Proof. This is proved in [3], using explicit calculations of the eta-invariants of lens spaces. $\square$

Theorem 5.7 Let $\pi$ be an elementary abelian $p$-group, where $p$ is an odd prime. Then $RH_* (B\pi)$ is generated (as an abelian group) by elements

$$x_1 \otimes \cdots \otimes x_j \in H_* (B\sigma_1) \otimes \cdots \otimes H_* (B\sigma_j),$$

with $\sigma_1 \times \cdots \times \sigma_j$ a subgroup of $\pi$ with each $\sigma_i$ a cyclic $p$-group.

Proof. We prove this by induction on the rank $r$. When $r = 1$, the statement is trivially true, and when $r = 2$, this is Proposition 5.6. Now assume the result for smaller values of $r$, and write $\pi = \pi' \times \mathbb{Z}/p$, where $\pi'$ has rank $r - 1$. We again use diagram (4.1) (with $k = 1$). The image of $\alpha$ is taken care of by inductive hypothesis. So consider the image of $\gamma$. Consider a representable class $\text{Tor}(x, y)$, where $y \in H_* (B\mathbb{Z}/p)$ and $x \in RH_* (B\pi')$. By inductive hypothesis, we may assume $x$ is the image of a representable class $x_1 \otimes \cdots \otimes x_j \in H_* (B\sigma_1) \otimes \cdots \otimes H_* (B\sigma_j)$, with $\sigma_1 \times \cdots \times \sigma_j$ a subgroup of $\pi'$ with each $\sigma_i$ a cyclic $p$-group.

It will suffice to show that $\text{Tor}(x_1 \otimes \cdots \otimes x_j, y)$ is of the correct form back in $H_* (B(\sigma_1 \times \cdots \times \sigma_j \times \mathbb{Z}/p))$. Represent each $x_i$ by a manifold $M_i \to B\sigma_i$, which is either $S^1$ or a lens space, and also represent $y$ by a manifold $L$ which is either $S^1$ or a lens space. Then $\text{Tor}(x_1 \otimes \cdots \otimes x_j, y)$ is represented by the homology Toda bracket $\langle [M_1] \times \cdots \times [M_j], p, [L] \rangle$. Since this Toda bracket is representable, it must be that $[M_1] \times \cdots \times [M_j]$ and $[L]$ have order $p$ in bordism, so that the homology Toda bracket lifts to a bordism Toda bracket, giving a class in $\Omega_* (B(\sigma_1 \times \cdots \times \sigma_j \times \mathbb{Z}/p))$. Indeed, the representable part of the Tor term in homology is the group generated by the images of the bordism Toda brackets $\langle [M], p^s, [L] \rangle$, and such a bracket maps to zero in homology whenever $s > 1$. Now consider the bordism Toda bracket $\langle [M_1] \times \cdots \times [M_j], p, [L] \rangle$. We know at least one of the $[M_i]$, say $[M_j]$, has order $p$. Then

$$\langle [M_1] \times \cdots \times [M_j], p, [L] \rangle = [M_1] \times \cdots \times [M_{j-1}] \times \langle [M_j], p, [L] \rangle \tag{[3], 2.1}$$

Now apply Proposition 5.6 to $\langle [M_j], p, [L] \rangle$, and this completes the inductive step. $\square$
Theorem 5.8 Let $\pi$ be an abelian $p$-group, and let $n \geq 5$. Suppose $M^n$ is a closed manifold with fundamental group $\pi$ and non-spin universal cover, and suppose $[M \to B\pi] \in H^n_{\text{an}}(B\pi)$. If $p = 2$, also assume $M$ is not orientable. If $p$ is odd, also assume $\pi$ is elementary abelian. Then $M$ has a metric with positive scalar curvature. In particular, if $n > \text{rank} \pi$, then every $n$-manifold with fundamental group $\pi$ and with non-spin universal cover has a metric of positive scalar curvature.

Proof. First consider the non-orientable case with $p = 2$. In this case, since there are no Tor terms,

$$H_n(B\pi, \mathbb{Z}/2) = \bigotimes_{i=1}^{\text{rank} \pi} H_*(B\pi_i, \mathbb{Z}/2),$$

where the $\pi_i$ are the cyclic factors of $\pi$. Now each class in $H_*(B\pi_i, \mathbb{Z}/2)$ may be represented by a manifold with nonnegative Yamabe invariant, or with positive scalar curvature if the class is in degree $> 1$. So it immediately follows that $H^n_{\text{an}}(B\pi, \mathbb{Z}/2)$ is represented by manifolds of positive scalar curvature. That takes care of the non-orientable case.

Now consider the case where $p$ is odd (and $M$ is orientable). We apply Theorem 5.7. This reduces us to the case of classes of the form $x_1 \otimes \cdots \otimes x_j \in H_*(B\sigma_1) \otimes \cdots \otimes H_*(B\sigma_j)$, with each $x_i$ represented by either $S^1$ or a lens space. The product manifold has positive scalar curvature unless all the $x_i$’s are 1-dimensional, in which case we have a toral class. \(\square\)

Problem 5.9 Are toral homology classes (for an elementary abelian $p$-group) represented by manifolds of positive scalar curvature? We suspect not, but we know of no way to approach this question.

Problem 5.10 Is Theorem 4.4 true without the odd order assumption? We presume so, but the proof would necessarily be much more complicated, since computing $ko_*(B\pi)$ for a 2-group is quite difficult.

Problem 5.11 Is Theorem 5.8 true for arbitrary abelian $p$-groups? Again we suspect so, but the necessary calculations are difficult.
