We present a class of systems for which the signal-to-noise ratio as a function of the noise level may display a multiplicity of maxima. This phenomenon, referred to as stochastic multiresonance, indicates the possibility that periodic signals may be enhanced at multiple values of the noise level, instead of at a single value which has occurred in systems considered up to now in the framework of stochastic resonance.

PACS numbers: 05.40.+j

In recent years, the phenomenon of stochastic resonance (SR) has been subject of intense activity, to the extent that many examples have been found in different scientific areas [1, 2]. The phenomenon has been characterized by the appearance of a maximum in the output signal-to-noise ratio (SNR) at a non-zero noise level. In this sense, noise plays a constructive role since an optimization amount is responsible for the enhancement of the response of the system to a periodic signal, which otherwise would be manifested with more difficulty. In spite of the efforts devoted to its understanding, there is an aspect which has not been considered up to now. Under some circumstances, the SNR may display a multiplicity of maxima and hence, there is a set of values of the noise level at which the response of the system is enhanced. In this Letter we address precisely this possibility for the class of systems for which the signal-to-noise ratio as a function of the noise level may exhibit any number of maxima.

Consider systems with only one relevant degree of freedom whose dynamics is described by the following Langevin equation

\[ \frac{dx}{dt} = -f(x, t)x + \sqrt{D} \xi(t) , \]

where \( f(x, t) \) is a given function, \( \xi(t) \) is Gaussian white noise with zero mean and second moment \( \langle \xi(t)\xi(t') \rangle = \delta(t-t') \), and \( D \) is a constant defining the noise level. Here the input signal enters the system through \( f(x, t) \), and we will assume it to be periodic in time with frequency \( \omega_0 \). The output of the system is given by \( v(x) = |x|^n \), with \( n \) a positive constant. The SNR is defined, as usual, by

\[ \text{SNR} = S(\omega_0)v(x)/N(\omega_0)v(x) , \]

where \( S(\omega_0)v(x) \) and \( N(\omega_0)v(x) \) are the output signal and output noise corresponding to \( v(x) \), respectively.

Under the transformation \( \tilde{x} = e^{\gamma t}x \) and \( \tilde{D} = e^{2\gamma}D \), with \( \gamma \) constant, Eqs. (1) and (2) remain unchanged if

\[ f(x, t) = f(xe^{\gamma}, t) . \]

Consequently, for the class of systems for which the previous equality holds, for a certain value of \( \gamma \), the SNR has the same value at \( D \) and at \( e^{2\gamma}D \). This fact occurs when \( f(x, t) = q(\ln(x), t) \), where \( q \) is a periodic function of its first argument, with periodicity \( \gamma \) if \( \gamma \) is the lower positive number satisfying Eq. (3). Therefore, the SNR is a periodic function of the logarithm of the noise level. Notice that both the signal and noise are not invariant under this transformation, but they are changed in the following fashion

\[ S(\omega_0)v(x) = e^{2\gamma n}S(\omega_0)v(x) , \]

\[ N(\omega_0)v(x) = e^{2\gamma n}N(\omega_0)v(x) . \]

In order to illustrate the previous results we have analyzed some representative explicit expressions of \( f(x, t) \). To this purpose we have numerically integrated the corresponding Langevin equation by means of a standard second-order Runge-Kutta method for stochastic differential equations [10]. Moreover, as the output of the system we have used \( v(x) = x^2 \). We will first consider the case in which

\[ f(x, t) = \Theta_T(\log_{10}(x^2))[\beta + \alpha \cos(\omega_0 t)] \]

where \( \alpha \) and \( \omega_0 \) are constants, and \( \Theta_T(s) \) is a square wave of period \( T \) defined by

\[ \Theta_T(s) = \begin{cases} k_1 & \text{if } \sin(2\pi s/T) > 0 , \\ k_2 & \text{if } \sin(2\pi s/T) \leq 0 , \end{cases} \]

with \( k_1 \) and \( k_2 \) constants. In Fig. 1(a) we have plotted the SNR corresponding to the previous form of \( f(x, t) \), for particular values of the parameters. This figure clearly manifests the periodicity of the SNR as a function of the noise level and the presence of multiple maxima at \( D = D_0e^{mT} \), with \( m \) being any integer number and \( D_0 \) the noise level corresponding to the maximum with \( m = 0 \). We show both the signal and noise in Fig. 1(b). This figure also corroborates the dependence of the signal and noise on \( D \) given in Eq. (3).

From this example one can infer the mechanism responsible for the appearance of this phenomenon. Due
to the fact that the SNR has dimensions of the inverse of time \([s^{-1}]\), its behavior is closely related to the characteristic temporal scales of the system. Thus variations of the relaxation time manifest in the SNR. In this example, when \(T\) is sufficiently large, for some values of the noise level the system may be approximated by \[
\frac{dx}{dt} = -k_i[\beta + \alpha \sin(\omega_0 t)]x + \sqrt{2D}\xi(t) ,
\] where \(i = 1, 2\), depending on the noise level. In such a situation the SNR is given by

\[
\text{SNR} = g(\alpha, \omega_0 k_i^{-1})k_i ,
\]

with \(g\) a dimensionless function. For a sufficiently low frequency, the SNR is proportional to \(k_i\) (SNR \(\approx\) \(g(\alpha, 0)k_i\)), i.e. proportional to the inverse of the relaxation time. Consequently, there are two set of values of \(D\) for which the SNR differs in approximately \(10\log_{10}(k_i/k_2)\) dB, as one can see in Fig. 1(c). We then conclude that multiple maxima in the SNR appears as a consequence of the form in which the relaxation time of the system changes with the noise level.

Let us now consider another explicit expression for \(f(x, t)\) that mainly differs from the previous one in the form in which the input signal enters the equation,

\[
f(x, t) = k \sin(2\pi \log_{10}(x^2)/T) + [\beta + \alpha \cos(\omega_0 t)] .
\]

Here the spatial and temporal dependence of \(f(x, t)\) appears in an additive fashion instead of in a multiplicative way as in Eq. (8). The results for the SNR are shown in Fig. 2(a) and also corroborate, in this case, the periodic dependence on the logarithm of the noise level.

The importance of the class of systems discussed previously lies in the fact that the periodicity of the SNR can be shown analytically by simple considerations about the invariance of the system under stretching transformations. Numerical analyses have also revealed that the presence of multiple maxima in the SNR as a function of the noise level is a more general phenomenon than the situation described by the equality (8). Thus, the appearance of multiple maxima is robust upon variations of the form of \(f(x, t)\). For instance, if the periodicity in \(s\) of the function \(q(s, t)\) is lost for high and low values of \(s\) then the SNR may be a periodic function of \(\ln(D)\) for a bounded range of values of \(D\). In this regard, we have performed numerical simulations and we have observed that it is possible to obtain any number of maxima depending on the form of \(f(x, t)\), even if the periodicity of \(q(s, t)\) does not hold for any interval of \(s\). As an illustrative example we will analyze a case in which the input signal enters \(f(x, t)\) in an additive fashion as well as in Eq. (1).

We will consider that the form of \(f(x, t)\) consists of two contributions; namely, one that comes from a time dependent parabolic potential and the other without temporal dependence. Then,

\[
f(x, t) = f_0(x) + [\beta + \alpha \cos(\omega t)] .
\]

Parabolic potentials may arise in many physical situations of interest. For instance, around a minimum most of the potentials may be approximated by a parabolic one. Experiments of a temporal variation of the intensity of the potential are common, this is the case of a single dipole under the influence of an external oscillating field \([\text{ Sec. 7}]\). Another remarkable situation described in the same way corresponds to some systems around a bifurcation whose control parameter varies periodically in time, as for example Rayleigh-B\'enard convection when the temperature difference between plates varies slowly in a periodic fashion \([\text{ Ref. 18, 19}]\). The term \(f_0(x)\) may then represent a perturbation to this ideal situation described by only a time-dependent harmonic force.

To be explicit and for the sake of simplicity, we will consider \(f_0(x)\) to be a linear piecewise function defined by

\[
f_0(x) = \begin{cases} k_1 & \text{if } |x| \leq c_1 , \\ k_2 & \text{if } c_1 < |x| \leq c_2 , \\ k_3 & \text{if } c_2 < |x| \leq c_3 , \\ k_4 & \text{if } c_3 < |x| \leq c_4 , \\ k_5 & \text{if } c_4 < |x| . 
\end{cases}
