Abstract

The utilization of plant food for therapeutic purposes can be seen as the biggest regard for natural flora, which provides bio-active materials that have medicinal values. Dietary fibres are acknowledged to be of significance. What has yet to be articulated is the composition of fibre in plant foods. More specifically in this commentary, the fibre in edible processed cassava product and the potential to make fibre supplement from the otherwise waste products have yet to be appreciated. Indeed, cassava has yet to be included in several studies on antidiabetic plants. It is known that cassava may be high in substances that are regarded harmful to humans, but about 80% of it is removed during processing of the tuber. What this commentary brings to the fore is that soluble fibres in cassava include uronic acid, pectin and β-glucans. These have nutraceutical values including hypocholesterolemic and hypoglycemic effects needed in diabetes management. These can be extracted to produce supplement of naturally-occurring dietary fibre that lowers plasma LDL, VLDL-cholesterol and triglycerides and blood glucose. This potentially improves the agricultural economics and medical nutritional values of cassava.

Introduction

In the health sector, studies on nutritive and phytochemical composition of cassava have reported different medicinal values. Though, what is common in the various reports is that none mentioned use of cassava for diabetes and dyslipidaemia management [1]. While there is opinion that cassava could be a healthier choice than wheat and white potatoes for diabetes patients [2], there is no scientific evidence in the literature on the use of cassava for diabetes and dyslipidaemia management. Further, there is no arguing the fact that a high-fiber diet is therapeutic [3], but diabetes patients are being discouraged from consuming cassava in favour of wheat [4]. Indeed, there has been furor over cassava [5]. The problem arising from this is that accessible and affordable staple carbohydrate food crop, cassava, is losing value on health grounds in favour of imported food products.

The furor calls for elucidation of information on international databases. For instance, a cursory review of the Australian National Survey Food Nutrient Database, comparing cassava with three other carbohydrate foods including wheat, will reveal that the energy with dietary fibre intake of wheat is 1119 kJ and without the fibre content is 784 kJ; whereas cassava is 587 kJ and 550 kJ respectively [6]. What is salient is that when the fibre content of the products are removed in processing, wheat loses most calorie than cassava. The information also indicate that wheat appears to have x9 of the fibre content of cassava (Table 1). However, a more critical review will show that while in the unprocessed food materials, low calorie/high fibre ratio is best in wheat compared to the others, low fat/fibre ratio is best in cassava (Figure 1).

It should be interesting to note that in patients with diabetes and/or metabolic syndrome, weight reduction is desired and high fibre diet could help in this regard [7]. In previous review [8], it has been explained that there is inconsistent fat/fiber ratio inferences of ≤5 and ≤25 [9,10]. Further, it is common practice to mix wheat flours with grinded products of cassava and yam. Bearing this in mind, comparison of the mixture cassava, taro and wheat contributions to the calorie, carbohydrate, fat and fibre in edible content show that cassava contributes almost equal amount of calorie, highest amount of fibre and least amount of fat (Figure 2).

Focus on fibre as a therapeutic ingredient

Cassava may be high in substances that are regarded harmful to humans, but about 80% of it is removed during processing of the tuber [11]. Some traditional foods such as root/tuber crops have been found to be of great importance in the management of diabetes globally due to the presence of many biochemical [12]. The Food and Nutritional Research Institute has performed a short-term investigation on the glycemic index and cholesterol-lowering effect of root/tuber crops and discovered that they are low in glycemic index (GI ≤ 55), because they release their glucose gradually into the blood [13]. According to the result, root/tuber crops have potential health benefits in the prevention for risk of chronic diseases such as cardiovascular diseases and diabetes mellitus.

Diabetes mellitus is a metabolic disorder that affects the way the body handles basic food components like carbohydrates, protein and fats. In the last 40 years, many people have become interested in promoting the potentials of indigenous plant foods in developing countries and utilizing them into modern health system, this is as a result of high cost of Medicare and side effect of therapeutic drugs [14].

The utilization of plant food for therapeutic purposes can be seen as the biggest regard for natural flora, which provides bio-active...
important health implication in the prevention of risk of chronic diseases such as cardiovascular diseases and diabetes mellitus [13]. Fiber has the ability to bind with bile acids and prevent its reabsorption in the liver thus, inhibit cholesterol synthesis. The viscous and fibrous structure of dietary fiber can control the release of glucose with time in the blood, thus help in the proper control and management of diabetes mellitus and obesity [13].

Cassava contains 40% of soluble fiber, which consists mainly of uronic acid, pectin and β-glucans [22], whereas the insoluble fraction is rich in cellulose and lignin [23]. There has been increasing drive to include food rich in fiber in the daily diet, and for this purpose cassava could be utilized because of its high content in dietary fibre. In particular, dietary fibres depending carbohydrates form of food and starch structures, are important determinants of low glycemic index food [23-25].

In a research conducted on the glycemic index of commonly consumed carbohydrate foods in Philippines [26], they reported that root/tuber crops are low in GI. Reducing the glycemic impact of diet using foods low in glycemic index has been shown to improve overall blood glucose control in patients with diabetes mellitus and obesity [27].

### Soluble fibre

Root/tuber crops are good sources of dietary fiber with up to 14% content [13]. Dietary fiber has been shown to have important health implication in the prevention of risk of chronic diseases such as cardiovascular diseases and diabetes mellitus [13].

Flora has made significant contributions towards the treatment of ill-health. The reliability on the use of medicinal plants in the developed societies has been traced to the extraction and development of several drugs from plants [15,24]. While dietary fibres are acknowledged to be of significance, what has yet to be articulated is the composition of fibre in plant foods [18-21].

For instance, a dietary fibre comprises soluble and insoluble types. Yet, nutrient databases indicate mainly the total fibre content with delineation into the sub-types.

**Table 1.** Some proximate nutrient values of cassava compare to other carbohydrate foods

| Food ID | Survey ID  | Food Name | Energy+ fibre (kJ) | Energy- fibre (kJ) | Protein (g) | Total fat (g) | Starch (g) | Total sugars (g) | Dietary fibre (g) |
|---------|------------|-----------|-------------------|-------------------|-------------|--------------|------------|-----------------|------------------|
| 13A11691 | 24302809   | Cassava   | 587               | 550               | 1.1         | 0.2          | 29.2       | 1.2             | 4.6              |

Cassava as a global carbohydrate food crop: implications for international adoption

About 60% of the world production of cassava is concentrated in five countries that spreads across Africa, Asia and South America [51]. other continents such as Oceania are also cultivating the food crop [52,53]. Global production is estimated to be highest in Africa and least in Oceania (Figure 3), but it is on the increase in the latter [53]. Thus, there is evidence of cassava being globally available for food and industrial utilization. What needs to be emphasized is the implication that if appreciated and integrated into diabetes management, either in medical nutrition therapy or pharmaceutical preparation of the dietary fibres, access to the raw material is worldwide.

Cassava is the third most important source of calories in the tropical Africa, after rice and maize. Millions of people depend on cassava in Africa, Asia and Latin America for their source of livelihood. The bulk of world trade in cassava is in the form of pellets and chips for feed (70 percent) and the balance mostly in starch and flour for food processing and industrial use. Only a relatively small part of world production of cassava is traded internationally. It is estimated that cassava ranks as the 850th most traded, and the 1192nd most complex product. While export value is worth almost a billion dollars (US$972 million) [54], it may be interesting to note two points from Figure 4 that:

- Africa, especially Nigeria is the largest producer of cassava, but yet to be among the top five exporters
- China and the United State swap first and second ranks topmost importers and exporters of cassava (Figure 4). That is, these populous countries are producing cassava and consuming.

Extractability of dietary fibre from cassava: implication for supplement production

Based on the foregoing discussion, the facts about dietary fibre in cassava is arguably no more a gain-saying. Perhaps, what needs to be emphasized is how to develop the MNT potentials of the food crop. Four salient points need to be highlighted in this regard

1. Studies on antidiabetic plants have yet to include cassava [1,36,55,56]. Therefore, the concept of producing dietary fibre supplement from cassava may be of interest, in addition to advancing the health value of the carbohydrate food
2. Supplement or extracts of naturally-occurring dietary fibre lowers plasma LDL, VLDL-cholesterol and triglycerides and blood glucose [7,57]. The implication of this is that supplements of dietary fibre can be, and are being made from food crops.
3. Cassava has become an alternative food source in poultry industry, but ironically, one of its limitation in the field is the high fibre content [58]. That is, the fibre content of cassava is being wasted in some industries

As previously reported, there is absence of pharmacological data on the health economics’ value of cassava in diabetes and dyslipidaemia management [8]. The issue of interest is that chief among staple food crops, worldwide, is cassava [39,40]. However, several studies emphasize its toxic potentials [41,42], thereby overshadowing the medicinal values. Many studies reflect on the glycaemic index [2,5,43-45], without recourse to the impact of processing [46]. This overshadows the potential that cassava can lower cholesterol level in diabetes patients [47]. Yet, it is known that cassava contains alkaloids and flavonoid glycosides with medicinal values [48, 49], as well as fibre [2], which can be translated for medical nutrition therapy management of diabetes and its cardiovascular complications including heart disease [50].

Cassava as a global carbohydrate food crop: implications for international adoption

About 60% of the world production of cassava is concentrated in five countries that spreads across Africa, Asia and South America [51].
4. The dietary fibres in cassava include uronic acid, pectin and β-glucans [22]. There are several reference on extraction of these nutrients from food products [59-65]. While this short paper is not focused on the details procedure of extraction or supplement preparation, it highlights the potential to enhance the agricultural and medical nutritional values of cassava.

Conclusion
This brief commentary has employed several references to buttress the facts about dietary fibre in cassava, is one of the macromolecules that have medicinal values. There is no gainsaying that dietary fibres content of cassava has yet to be appreciated in several studies on antidiabetic food crops. What this commentary advocates is that soluble fibres in cassava have nutraceutical values including hypocholesterolemic and hypoglycemic effects needed in diabetes management. Given the knowledge that the fibres can be extracted to produce supplement of naturally-occurring dietary fibre lowers plasma LDL, VLDL-cholesterol and triglycerides and blood glucose, it behooves to improve the agricultural economics and medical nutritional values of cassava.

Authorship and contribution
All authors have contributed to this work. EUN conceptualized the work and drafted the manuscript with BCO. RJC reviewed the agricultural economics concept and the manuscript.

Acknowledgement
This work is part of doctorate research literature, which in turn is a piece of work in the 2nd phase of CVD risk assessment in prediabetes and undiagnosed diabetes mellitus study. The commentary is an extension of presentation done at the 6th International Conference on Research in Chemical, Agricultural & Biological Sciences (RCABS-2017) in Singapore 2017.
