Received: July 03, 2020 Revised: July 25, 2020 Accepted: August 10, 2020

Abstract

The human and capital resources from foreign investors are important sources of finance for developing countries. Foreign ownership can help the firm to raise funds for operations and the foreign management can help the firm expand the market and improve management. However, does this really happen to Vietnamese firm? To find the answer to that question, this paper examines the impact of foreign ownership and management on the financial performance of listed firms on Vietnam’s stock market. The data collected include 427 listed firms in all fields over five years, from 2014 to 2018. The financial performance is measured by Tobin’s Q, ROA and ROE. The study carried out testing of each model by the least squares method of Pool OLS, assessing random effects (REM) and evaluating fixed effects (FEM). The most effective model is the FEM model. The results show that the foreign ownership ratio and the size of the firm have a positive impact on the financial performance. The foreign management, the age of the firms, the liquidity and financial leverage have a negative impact on the financial performance. Based on the research results, the study proposes some recommendations to improve the financial performance of listed firms in Vietnam.

Keywords: Foreign Ownership, Foreign Management, Financial Performance

JEL Classification Code: G30, M40, M41

1. Introduction

Economic growth is an important goal of every country. To achieve and maintain that goal, each country will have policies and steps appropriate to their specific circumstances. However, any country must answer the question of where resources for economic development investment lie and how to mobilize those resources. In the trend toward globalization, in order to survive and develop, each economy must bring into play internal resources in combination with external resources. It has been over 30 years of development since Vietnam carried out economic policies to attract and receive foreign investment capital. By now, the foreign-invested economic sector has been increasingly displaying its important role and significant contribution to the socio-economic development of the country. Especially, since the Law on Investment No. 67-2014-QH13 officially came into effect in 2015 and the relaxation of foreign ownership was carried out, stable foreign capital flows have been attracted into the Vietnamese stock market. The strong increase in the number of multinational investment flows has promoted economic development in general and the performance of enterprises in particular. In the coming period, Vietnam continues to affirm that the foreign-invested economic sector is an important component of the national economy. This sector is encouraged for long-term development in

suggest that foreign ownership positively affects financial
efficiency only up to a certain ratio; after that, the increase of foreign ownership ratio does not lead to profit increase for firms. Greenaway et al. (2009) showed the relationship between foreign ownership and performance of firms in China through an inverted-U-shaped graph. Financial performance of firms increased when foreign ownership ratio increased by 47% to 64% and then decreased. Firms with controlling foreign ownership ratio of 51% would achieve outstanding business performance (Douma et al., 2006). This research result is also consistent with the conclusion of a study by Gurbuz and Aybars (2010) about listed companies in Turkey. The study by Park (2002) on industrial firms listed on the Tokyo Stock Exchange showed a linear curve about the relation between Tobin’s Q and the foreign ownership ratio. Accordingly, the increase in foreign ownership led to the increase in financial performance; however, when the foreign ownership ratio increased to about 40%-45%, financial performance increased, then decreased. This study also showed that, in Japan, big foreign investors often invested in large and well-managed firms. In Vietnam, Nguyen and Nguyen (2013) divided firms into four groups with foreign ownership ratio ranging from 10% to 49% to study; they found out that the foreign investment ratio of about 20-50% would have a clearer positive impact on the ROA of firms, while the ROE would only be affected in firms with foreign ownership ratio of less than 10%.

However, there are many studies with contrasting results about this positive impact (Xu & Wang, 1999; Abbas et al., 2009). When considering the impact of the ownership structure on the operation of firms in Malaysia, these studies showed that ROE had no correlation with foreign ownership. The analysis by Lee (2008) about the impact of the ownership structure on enterprise value of firms in Korean also suggested that there was no evidence of the impact of foreign ownership on ROA of firms in this country. In Vietnam, the study by Nguyen and Ngo (2017) produced negative results about this relationship in real estate firms. Nguyen (2018) and Doan (2014) stated that the foreign direct investment ratio in general did not show signs of impact on financial performance.

The impact of foreign management also attracts the attention of researchers. Different measurement scales of financial performance like Tobin’s Q, ROA, ROE, and ROS all show that, if the executive board has a participation of board members from diverse nationalities, the financial performance will be higher. The studies by Choi et al. (2007) about firms in Korea, and by Saleh et al. (2009) about firms in Malaysia, showed the positive impact of foreign management on financial performance. According to the study by Oxelheim and Randoy (2003) about firms in Norway and Sweden, firms with board members who are British and American nationals had higher Tobin’s Q higher

2. Literature Review

When studying the impact of foreign ownership on financial performance, most of the previous studies applied panel data and the following commonly-used research methods: Pooled Ordinary Least Square (Pooled OLS), Fixed Effects Model (FEM) and Random Effects Model (REM); they then drew conclusions based on the most appropriate model. Few studies used the Generalized Method of Moments (GMM). In addition, due to the differences in scopes of studies regarding space and time as well as differences in measurement scales for financial performance, results about the relationship between these two factors are not the same.

In Ukraine, Olga (2009) distinguished the impact of different ownership objects and internal issues of enterprise ownership rights. FEM test showed no link between foreign ownership and financial performance; however, deeper analysis of ownership objects using the GMM method revealed the positive relationship between these factors in firms with invested capital from the group of developed countries. Studies by Chibber and Majumdar (1999) and Douma et al. (2006) used data from foreign-invested companies in India and the cross-sectional regression method to find evidence of the positive impact of foreign investment on ROA and ROE of these firms. Studies by Wei et al. (2004) and Estrin et al. (2009) on firms in China, and studies by Baek et al. (2004) and Park (2004) about firms in Korean were carried out at different times, but all achieved the same result, namely, that foreign ownership has a positive impact on the Tobin’s Q and even has more impact than other types of ownership (Wei et al., 2004). When studying Vietnamese firms with the main research methods as Pooled OLS, FEM, REM, or GMM, many authors found evidence of the positive correlation between these factors. For example, Vu et al (2019), Nguyen and Dang (2017), Dinh and Ho (2017), Nguyen and Pham (2017) showed that foreign ownership in Vietnam has positive impact on financial performance at the significance level of 1%-5%. This positive correlation was explained by the authors based on the advantages that foreign investors bring to firms.

In spite of this positive correlation, some studies suggest that foreign ownership positively affects financial
3.1.1. Ownership Theory

The theory of ownership suggests that the difference in ownership will affect owners’ motivation and behavior (Alchian & Demsetz, 1973). This theory emphasizes the concentration of ownership in the form of private ownership, which will motivate management to create better business efficiency than the dispersion of public ownership. The private sector will have better operational efficiency than the state sector. According to Alchian and Demsetz, private ownership can improve the relationship among motivation, interests and behaviors of owners, executives and employees. Meanwhile, the lack of clarity in public ownership will negatively affect the motivation of executives, important decisions of firms and dealing with the consequences of decisions brought about by collective ownership.

3.1.2. Agency Theory

The representation theory is considered the fundamental theory related to operational performance. This theory shows the relationship between the representatives and owners; it was first articulated by Jensen and Meckling (1976), then later further developed by Fama and Jensen (1983). According to this theory, because some executives have special skills and better knowledge of company management than the owners, owners are willing to hire and delegate management responsibilities and the rights of making control decision to them (Fama & Jensen, 1983). Agents, on behalf of the owners, carry out the management of the company, but only receive the majority of their benefits from salaries. However, both of these entities may want to maximize their benefits, and conflict of interest may arise. To reduce this conflict and improve the operational performance of the company, the owners must accept agency costs (Jensen & Meckling, 1976). Agency cost is defined as the total of cost categories including (i) the cost of control, which is the cost paid to the controllers to inform shareholders when the executives have profiteering activities for their own benefits, (ii) binding costs are the costs to prevent the negative consequences that may occur from the dishonest actions of executives, and (iii) the additional losses, which are charges related to damages caused by their agents who use their power for personal gain.

3.2. Research Model

Based on the literature reviewed, the proposed research model is as follows:

\[ FP = \beta_0 + \beta_1{FO} + \beta_2{FM} + \beta_3{GROW} + \beta_4{AGE} + \beta_5{SIZE} + \beta_6{LIQ} + \beta_7{LEV} + \varepsilon \]

In which:

- **The dependent variable** is financial performance (FP) is measured by Tobin’s Q, ROA and ROE.
- **Tobin’s Q**: This is the market value of firms which is calculated by the market value of capital/ the book value of capital
- **ROA**: This is a measure of financial performance calculated by dividing net income by assets.
- **ROE**: This is a measure of financial performance calculated by dividing net income by shareholders’ equity

**Independent variables include:**

- **Foreign ownership (FO)**: This is the ownership ratio of foreign investors and is calculated by the total number of shares held by foreign shareholders divided by the total number of outstanding shares
- **Foreign management (FM)**: This is the management participation of foreigners in firms and is measured by the number of foreigners participating in management in firms.
Control variables include:

- Revenue growth rate (GROW): This is the growth rate of net revenue, which is calculated by subtracting the net revenue of the previous year from the net revenue of the following year, then then dividing by the net revenue of the previous year.

- The age of the firm (AGE): This indicates the years of operation of firms since establishment until the year of study.

- The size of the firm (SIZE): This shows how big a firm is and is calculated by logarithm of total assets.

- Liquidity (LIQ): This is the payment ability of a firm and is calculated by dividing short-term asset by total liabilities.

- Financial leverage (LEV): This shows the financial capital structure of a firm and is calculated by dividing total liabilities by total assets.

3.3. Hypothesis

According to ownership theory, agency theory and previous studies, the hypotheses about the impact of foreign ownership and management as well as control variables on financial performance are formulated as follow:

3.3.1. Foreign Ownership Ratio

According to the ownership theory, ownership motivates firms to make the most efficient use of resources to maximize profits. Results of previous studies show that a capital investment/contribution relationship often goes beyond financial contributions and extends to training, management transfer, and technical cooperation. A number of studies in different countries also show a positive relation between the foreign ownership ratio and financial performance of firms such as Olga (2009), Chhibber and Majumdar (1999), Douma et al. (2006), Vu et al. (2019), Nguyen and Dang (2017). In contrast to the above studies, some authors such as Xu and Wang (1999), Lee (2008), Abbas et al. (2009), and Nguyen (2018) found no indication that foreign ownership ratio was correlated with financial performance of firms. The hypothesis of the independent factor that foreign ownership ratio affects financial performance is created as follows:

**H1:** The foreign ownership ratio has a positive impact on financial performance

3.3.2. Foreign Management

According to previous studies, the presence of foreigners in the corporate management system may bring competitive advantages to firms through expanding international networks (Oxelheim & Randoy, 2003), widen the consumption market and improve business efficiency. Moreover, foreign-controlled companies can arrange technical cooperation, nominate foreign directors on the board, arrange activities of consultancy and marketing, branding, patent obligations and share management resources (Dhar et al., 1988) help improve financial efficiency. Research results of Oxelheim and Randoy (2003), Ruigrok and Kaczmarek (2008), Choi et al. (2007) show that financial performance of firms with members of diverse nationalities in top management is higher than that of local firms. Contrary to this assumption, the study by Rose (2007) found no evidence of the impact of foreign management on financial performance. The hypothesis of the impact of foreign management on financial performance is as follows:

**H2:** Foreign management has a positive impact on financial performance

3.3.3. Control Variables

Growth is one of the basic conditions for firms to achieve their goals during production and business activities. Growth helps firms accumulate capital and facilities to invest in expanding production and build credibility with customers as well as with suppliers, investors. According to previous studies, firms with high growth rates often have good financial performance growth can help generate profits from investment. Research by Ntim and Osei (2011), Costea (2012) showed that revenue growth has positive impact on ROA but negative impact on ROE. In Vietnam, however, the research results by Huynh (2016) showed a positive relationship to both ROA and ROE variables. The hypothesis for the revenue growth variable in this research is:

**H3:** Revenue growth rate has a positive impact on financial performance

According to previous studies, firms have been operating for a long time can accumulate a lot of capital to finance their business activities as well as new investment projects. At the same time, these firms often have a lot of experience and gain credibility and extensive social relationships with other firms or commercial banks. As a result, it is easy for them to have access to capital and information related to their business operation; their operation efficiency is also high. Studies by Gurbuz and Aybars (2012); Maleya et al. (2013) showed that the longer a firm operates, the higher the financial performance, but Chhibber and Majumdar (1999) and Huynh (2016), Homaidi et al (2020) indicated the opposite. Therefore, the authors proposed the hypothesis for the impact of age of firm on financial performance as follows:
**H4:** Age of firm as a positive impact on financial performance

The size of firm is important to business performance because it represents a firm’s resources. According to Doan (2014), large firms with well-organized resources and good-quality machinery and equipment easily achieve their goals. Empirical research results show that, regardless of the group of criteria to evaluate the efficiency, there are three different directions. According to Huang and Wang (2011), the larger the firm size, the higher the financial performance because such firm has advantages in finance, organizational structure, technology level. But Lauterbach and Vaninsky (1999), Tian and Zeitun (2007) found no indication of the impact of firm size on financial performance. Based on previous research results, the authors created the hypothesis for the factor of firm size by asset as follows:

**H5:** Firm size has a positive impact on financial performance.

The international financial reporting standards (2006) define liquidity as cash available in the near future, taking into account the related financial obligations in that period. Liargovas and Skandalis (2008) argued that firms may use current assets to finance their activities and investments when external financial resources are not available. Almajali et al. (2012) found that liquidity has a significant impact on financial performance. But, in contrast to the above argument, the theoretical model of Jovanovic (1982) suggests that a moderate amount of liquidity can boost business performance, but having too much liquidity may be detrimental to business efficiency. The hypothesis for this factor is set as follows:

**H6:** Liquidity has a positive impact on financial performance.

According to Quan and Ly (2014), a typical characteristic of Vietnamese firms is that they often have very high debt ratios, which significantly affects business performance. High debt ratios lead to increasing interest expenses and reducing profits, which has a significant impact on ROA and ROE. According to Berger and Patti (2006), financial leverage has a positive effect on dependent variables about financial performance. On the other hand, Astami et al. (2010), Chu Thi Thu Thuy et al. (2015), Nguyen and Nguyen (2020) suggested that financial leverage has negative impact on financial performance. However, according to Alipour (2012), financial leverage has a positive impact on ROE and negative impact on ROA and ROS. As studies with different spaces yielded conflicting results, the authors put the leverage variable into the model and set up the 7th hypothesis as follows:

**H7:** Financial leverage has a positive impact on financial performance.

### 3.4. Data

To achieve the research objectives according to the above model, the authors use the data source that included information about financial statements and related information of firms listed on the Vietnamese stock market during the 2014-2018 period. According to the research purpose and scope, the authors removed firms in the financial sector and those with insufficient data in the research sample. After collecting and synthesizing data, the total number of firms in the sample was 427; these firms had enough data and meet information requirements.

### 3.5. Research Method

The verification process of these models was carried out in turn through such tests as descriptive statistics and multicollinearity tests. Each model was verified using Pooled OLS, REM and FEM methods. The selection of an effective model was done by Hausman or Lagrange test; after that autocorrelation and variance of variance were tested and the general regression model (GLS) was used to correct defects and draw conclusions.

### 4. Research Results

#### 4.1. Descriptive Statistics

Using the Stata software, the dependent, independent and control variables in the model are summarized on Table 1.

- The average Tobin’s Q coefficient of firms in the survey sample was 1.16, which proved that firms were rated on the market higher than their book value. In particular, the highest-rated firm was rated 10.176 times higher than its book value, while the lowest-rated firm was rated as 0.093 times of its book value.
- The average ROA of firms in the research sample was 0.069 with the highest ROA of 0.72 and the lowest ROA of -0.99.
- The average ROE of firms in the research sample was 0.132 with the highest ROE of 1.61 and the lowest ROE of -1.69.
- The average foreign ownership ratio of firms in the research sample was 13.41% with the highest investment ratio of 78% and the lowest of 0%.
- The average number of foreign members in the board of directors or board of management of firms in the research sample was 0.25 people. In the research sample, the highest number of foreign board members in firms was 6.
- The average revenue growth rate of firms in the search sample was 19.81% with the highest rate of 955.6% and the lowest rate of -103.9%.
- The average age of firms in the research sample was 11.45 years. There was even a firm which has been in operation for 25 years by 2018.
- The scale of firms according to the natural logarithm of the total assets was the average of 27.24 with the highest value of 33.294 and lowest value of 21.219.
- The average liquidity of firms in the research sample reached 2.59 times. There were firms with very low liquidity at 0.05 times and those with overly high liquidity of 67.14 times.
- The average financial leverage of firms was 0.478. There were firm using very little loans, only at 0.006, and those used most of loans for their production activities (0.993).

### 4.2. An Empirical Model

The authors used Pooled OLS, REM and FEM, methods as well as the Hausman test to choose a suitable model between FEM and REM. Test results of two dependent variables are shown in Table 2. The significant value of three models were all < 0.05, showing that the FEM model was more suitable than the REM model. As a result, the FEM model was selected for further tests.

### 4.3. Defects of the Model

Once the FEM model was selected for all three dependent variables, the authors examined the model’s defects including multicollinearity, autocorrelation, and variance of variance.

### Table 2: Results of Hausman test on ROA, ROE models

| Variable  | Tobin’s Q | ROA  | ROE  |
|-----------|-----------|------|------|
| Statistical value | 39.99 | 45.79 | 65.28 |
| Sig | 0.0000 | 0.0000 | 0.0000 |

### Table 3: Variance Inflation Factor

| Variable | VIF | 1/VIF |
|----------|-----|-------|
| LEV      | 1.58 | 0.63329 |
| FO       | 1.44 | 0.69503 |
| SIZE     | 1.35 | 0.74249 |
| FM       | 1.34 | 0.74595 |
| LIQ      | 1.33 | 0.75136 |
| AGE      | 1.04 | 0.96382 |
| GROW     | 1.02 | 0.98063 |
| Mean VIF | 1.30 |

**Multicollinearity:**

The authors used the Variance inflation factor (VIF) to test multicollinearity with the following results (see Table 3). The VIF factors of all variables in the model were <10, proving that multicollinearity didn’t occur with variables in all three models.

**Autocorrelation:**

The authors used the Wooldridge test for autocorrelation in each model with the following results (see Table 4). The test results show that autocorrelation occurred in the Tobin’s Q and ROA models, but not in ROE models. To overcome autocorrelation, the authors used a stronger regression model (GLS).
Variance of variance:

With FEM as the chosen model, the authors used Wald test for variance of variance in research models with the following results (see Table 5). Test results show that variance of variance occurred in all three models. The authors used the GLS model to overcome this defect.

4.4. Regression

The GLS model was used for all three dependent variables. Autocorrelation and variance of variance were fixed in the Tobin’s Q and ROA models while only variance of variance was fixed in the ROE model. Regression results of three models are shown in Table 6.

4.5. Discussion

According to the research results of 427 firms listed on the Vietnamese stock market, foreign ownership ratio does not show signs of impact on Tobin’s Q; however, it has a positive impact on the ROA and ROE. This result is consistent with the research results by Olga (2009), Chibber and Majumdar (1999), Douma et al. (2006); Dinh and Ho (2017).

Foreign management has positive impact on Tobin’s Q. This conclusion is consistent with research results by Choi et al. (2007) and Oxelheim and Randoy (2003). In fact, according to previous studies, when listing on the stock exchange, firms also want to improve financial performance to attract more investment (Nguyen & Nguyen, 2013). At the same time, the participation of foreign investors increases the reputation of firms in domestic and international markets, helping to improve their market value.

However, foreign management has negative impact on ROA and ROE (with ROA, the reliability was only at 90%); such result is consistent with research results by Rose (2007), Joenoes and Rokhim (2019), but contrary to those by Oxelheim and Randoy (2003), Ruigrok and Kaczmarek (2008), and Choi et al. (2007). This is probably because foreign management does not necessarily mean that foreign investors participated in management and firms hired foreigners in the international market to run and manage the business. As a result, management costs will be higher than hiring a local executive. In addition, with improving technology, the quality of services and products or increasing training costs also put more pressure on firms, leading to a decline in the profitability. Moreover, the Ministry of Planning and Investment’s surveys on FDI firms in recent years have shown that on average, 70% of FDI firms declare annual losses due to transfer pricing or a number of FDI firms make profits but have very low ROS ratio. Firms with foreign management maybe able control and adjust the profit so their financial performances are not high.

Revenue growth has negative impact on Tobin’s Q and ROA, but was positively related to ROE. This result is consistent with the research results on ROE variables by Huynh (2016), but contrast with the research results by Ntim and Osei (2011) and Costea (2012). In fact, the revenue growth rate of firms reflects the economic potential, stability and the growth of firms, thereby increasing profits for firm

| Variable | Tobin Q | ROA | ROE |
|----------|---------|-----|-----|
| Beta     | Sig     | Beta | Sig | Beta | Sig |
| FO       | 0.0491  | 0.105 | 0.0320*** | 0.000 | 0.1040*** | 0.000 |
| FM       | 0.0186*** | 0.003 | -0.0023* | 0.053 | -0.0080*** | 0.000 |
| GROW     | -0.0061** | 0.035 | -0.0089*** | 0.000 | 0.0214*** | 0.000 |
| AGE      | -0.0062** | 0.000 | -0.0010*** | 0.000 | -0.0024*** | 0.000 |
| SIZE     | -0.0033 | 0.189 | 0.0008 | 0.134 | 0.0033*** | 0.000 |
| LIQ      | -0.0033** | 0.005 | -0.0008* | 0.020 | -0.0029** | 0.000 |
| LEV      | -0.0169 | 0.466 | -0.1270*** | 0.000 | -0.0650*** | 0.000 |
| Cons     | 1.2069*** | 0.000 | 0.1112*** | 0.000 | 0.0894*** | 0.000 |
| R-Square | 15.0 | 22.3 | 18.4 |

Note: ***, ** and * indicates significant at 1%, 5% and 10% level of significance based on t-statistics
owners. However, when firms have high revenue growth rates and they expand investment activities or pay dividends by shares, the owner’s equity is diluted while the market value of capital does not keep pace with the equity growth rate. This may cause the enterprises’ Tobin’s Q coefficient to decrease.

Surprisingly, the research results show that the age of firm has negative impact on all three measurement variables of financial performance of firms. This means that the higher the age of a firm, the lower the market value of capital and profitability. This research result is similar to those by Chhibber and Majumdar (1999), Huynh (2016), but contradict those by Gurbuz and Aybars (2012), Maleya et al. (2013), Nguyen and Ngo (2017). According to Huynh (2016), the longer the firms operate in the market, the more stagnant they become and do not switch timely to high-performing industries and fields. Besides, the society is growing; new fields and markets are constantly developing. Young firms may be able to seize the opportunities and find ways to penetrate the market, so they constantly built up reputation and improve product quality in order to exist and develop. Therefore, the age of firm is not a factor that helps a firm improve its financial performance.

Size of a firm positively affects ROE, but does not show any signs of impact on Tobin’s Q and ROA. This result is consistent with the research results by Gurbuz and Aybars (2012), Maleya et al. (2013), but contrary to the research results by Nguyen and Ngo (2017). This can be explained by the fact that, if firms invest in expanding their sized, especially increasing fixed assets, they will help firms produce products with higher quality, aesthetics, and taste. In addition, firms with bigger size have better reputation than those of small sizes and also better competitive edges; this can help firms improve their profit and financial performances.

Liquidity of a firm has a negative impact on all three measurement scales of financial performance. This result is consistent with the research results by Almajali et al (2012), Nguyen and Ngo (2017), but contrary to the results by Paris (2010). For firms, short-term liquidity is a very important indicator for company executives. However, according to this research result, liquidity ratio of firms is very high (2.56 times), which means firms have too many short-term assets compared to short-term liabilities. This can lead to inefficient use of short-term assets and may become an indirect cause of financial performance decline.

Financial leverage has a negative impact on financial performance of firms. This result is consistent with the results by Zeitun and Tian (2007), Nguyen and Nguyen (2013), but is contrary to the results by Nguyen and Ngo (2017). It can be seen that firms in Vietnam typically have very high debt ratios, which can theoretically be a lever to amplify the profits of businesses, but also cause an increase in interest expenses and eventually a decrease in profit. In addition, a high debt ratio may affect the ability of a firm to get loans and the pressure to pay interest and principal will make it difficult for a firm to operate.

5. Conclusions and Recommendations

The authors studied and collected data of 427 listed companies on the Vietnamese stock market from 2014 to 2018. After performing the necessary tests to select and overcome the defects of the OLS, FEM and REM models, the authors used GLS test to assess the impact of foreign ownership and management on financial performance. The results show that foreign ownership ratio positively affects ROA and ROE, but shows no signs of impact on Tobin’s Q; foreign management has a positive impact on Tobin’s Q, but negatively impact on ROA and ROE. Regarding control variables, revenue growth and financial leverage show no signs of impact on Tobin’s Q, but has negative impact on ROA and ROE. The size of the firm alone does not affect both Tobin’s Q and ROA; liquidity has a negative impact on all three measurement scales.

Through the research results, in order to improve the financial performance of listed companies on Vietnamese stock market, the authors present the following recommendations:

Firstly, firms need to be transparent and disclose their business results in accordance with current regulations and with the approach of international standards (IFRS). Transparency and disclosure of information will help firms improve their reputation in the market. At the same time, it helps foreign investors analyze information of firms more accurately and attract more investment capital from these investors.

Secondly, firms need to proactively build specific business strategies and plans to attract investors, while offering reasonable dividend policies to encourage foreign investors.

Thirdly, firms need to strictly control indirect capital into their units, monitor the moves of professional investors, co-operate with the government and the financial, banking supervision system to effectively manage indirect capital.

Fourthly, firms should consider increasing the number of Vietnamese members on the board of directors and board of management and limit hiring non-Vietnamese nationals to join these boards. If necessary, firms should only hire a team of foreign experts for a certain period of time for certain situations and projects; domestic human resources should be utilized for the whole process of administration and management.
