Sensitive Variable Analysis for Comprehensive optimization of an SWATH-USV

Wang Baojiang, Tang Xiongfeng, Yang Songlin, Qiu Menglong

Abstract— In this paper, aiming at the comprehensive optimization of SWATH, we establish a optimization mathematical model of SWATH. And use genetic algorithm to carry out the comprehensive optimization calculation. To solve the problem of premature convergence of genetic algorithm, we adopt parallel strategy to improve the efficiency of the algorithm on three design variables: Loa, speed item. In order to improve the parallel efficiency of the algorithm, we have carried out sensitivity analysis propeller diameter, and obtained the analysis results. The research results can provide a reference for the multi-objective, multi-variable and multi-constrained comprehensive optimization of the performance optimization of SWATH.

Index Terms— Swath-USV; Comprehensive optimization; Genetic algorithm; Parallel strategy; Sensitive variables;

I. INTRODUCTION

Small Waterline Catamaran (SWATH-USV) was first built in 1973 and developed rapidly in the 1980s. As a high performance ship, small water plane catamaran has the advantages of good wave resistance, high propulsion efficiency, large hull deck area and good transverse stability. For Small Waterline Catamaran, it is of great significance to obtain the optimal ship type and improve the performance by scientific and effective calculation. In the process of ship form optimization research, Ma Weijia [1], hua-wei sun, yong-jie pang, Guo Zhiqun, Yang Heng transformed the boat optimization problem under given constraints into a constrained mathematical optimization problem for finding the functional extremum. Through nonlinear programming optimization theory, The objective function constrained by the given main parameter type. And they find the optimal ship form. Yang zhuoyi [2], pang yongjie, wang jian and song lei studied the experimental design, response surface model technolometers of the hull is minimized conditionally to solve the optigy and multi-objective optimization algorithm for the submarine's boat type optimization. In terms of optimization algorithm, genetic algorithm, as a random search and optimization method based on biological natural selection and genetic mechanism, has high efficiency in solving complex problems. Chen kaifeng [3] discussed various implementation methods using genetic algorithm and compared their advantages and disadvantages, demonstrating the effectiveness of genetic algorithm in solving multi-objective optimization problems. Goldberg[4] proposed the idea of designing parallel structure of genetic algorithm based on object. Aiming at the problem of premature convergence of genetic algorithm, zhou yuanhui [5], lu yuchang and shi chunyi proposed the idea of combining multi-population parallel evolution and adaptive adjustment control parameters to alleviate the problem of premature convergence. It improves the efficiency of the non-inferior hierarchical multi-objective genetic algorithm and makes up for the disadvantages of the genetic algorithm, such as poor local search ability and precocity.

For the problem of multi-objective comprehensive optimization in SWATH-USV , this paper selects corresponding design variables to establish a comprehensive optimization mathematical model, selects genetic algorithm as the optimization algorithm, and seeks for sensitive variables in Loa L , design speed V and propeller diameter Dp, so as to improve the parallel efficiency of the algorithm.

II. OPTIMIZATION MODEL OF SWATH-USV

A. Rapidity

According to the theory and experience, this paper synthetically considers the selection of design variables: the length of the submerged body Loa , the diameter of the submerged body Dp, The length of the pillar Lt , Maximum strut width It , the Loa L , the width of the ship B , the draft T , the longitudinal position of the buoyancy center Lpr , the diameter of the propeller Dp , the disk-to-surface ratio Aeo , the pitch ratio Dp , the speed of the propeller N , and the designed speed V s. Represented by a vector :

\[ X = \{L_o, D_p, I_t, L, B, T, L_p, D_p, A_eo, P_p, N, V_s\} \]

The objective function takes the speediness criterion factor similar to the naval coefficient form as the speediness optimization objective function:

\[ f_1(x) = C_{sp} = \frac{V_s^{\frac{2}{3}}A^{\frac{2}{3}}}{P_E} = \frac{V_s^{\frac{2}{3}}(\eta_p)P_pN}{R(V_s)^{\frac{3}{2}} \Delta} \]

In the formula : Effective power \( P_E \) (unit: horsepower); \( \Delta \) Drainage (unit: ton); \( V_s \) Design voyage (unit: knot); \( R \) Hull resistance (unit: N); \( \eta_0 \) Open water efficiency of propeller; \( \eta_p \) Hull efficiency; \( \eta_R \) Relative rotation efficiency; \( \eta_s \) Shafting efficiency.

Wang Baojiang, Tang Xiongfeng, Yang Songlin, Qiu Menglong, School of Naval Architecture & Ocean Engineering · Jiangsu University of Science and Technology, Zhenjiang, Jiangsu, China
B. Seakeeping

In this paper, the rolling natural period is selected as the objective function for the study of the mathematical model of seakeeping. Selection of design variables: \( L_0 \), ship width \( B \), draft \( T \), square coefficient \( C_B \), waterline coefficient \( C_w \), demi hull spacing \( C_e \), center of gravity height of catamaran \( Z_c \). Represented by vector \( X \), that is:

\[
X = \{ L, B, T, C_B, C_w, C_e, Z_c \}
\]

For catamaran, its stability is good, but its rolling cycle is short, especially at high speed. In this paper, \( \omega_0(x) \) - the natural period of a ship is chosen as the objective function of seakeeping, and its expression is as follows:

\[
f_3(x) = T_0 = \frac{2\pi}{\omega_0} = 2\pi \sqrt{\frac{I_i}{\Delta h}} (2-2)
\]

In the formula, the natural rolling period is \( \omega_0 \) = \( \sqrt{(\Delta h) / I_{xx}} \) (s\(^{-1}\)), the sum of inertia moment and additional inertia moment of the hull itself is \( I_{xx} \), displacement is \( \Delta \), the initial stability of the ship is \( h \), the inertia moment of the hull itself is \( I_{xx} \), and the additional inertia moment is \( J_{xx} \).

C. Maneuverability

In this paper, heading stability is taken as the research object of maneuverability to select design variables. Considering comprehensively, the selected design variables are \( L_0 \), ship width \( B \), draft \( T \), square coefficient \( C_B \) and waterline length \( L_c \). Representation by a vector:

\[
X = \{ L, B, T, C_B, L_c \}
\]

We selected linear stability as the objective function of maneuverability of Small waterplane catamaran, which is expressed by the linear stability criterion coefficient \( C \). Linear motion stability is determined by the changing characteristics of state variables \( v \) and \( r \). The stability of the system is directly related to the four acceleration hydrodynamic derivatives and the four velocity hydrodynamic derivatives \( Y, Y, N, N, N, N \), which can be expressed by the linear stability criterion coefficients of ships \( C \) :

\[
f_3(x) = c = Y \cdot N - N \cdot (Y - m) (2-3)
\]

D. Constraints

1. Equality constraints

   1. Floating constraints in static water, i.e. the drainage obtained by USV optimization is consistent with the design drainage:

   \[
   \Delta = LBHC \rho (2-4)
   \]

   2. Thrust resistance balance constraint, that is, the effective thrust of the propeller is equal to the hydrodynamic torque of the hull:

   \[
   N_p K_T \rho N^2 D_p^{1.5} (1-t) = I_0 (2-5)
   \]

3. Torque balance constraint, i.e. the torque supplied by the main engine to the propeller is equal to the hydrodynamic torque endured by the propeller:

\[
\frac{\eta_{\Delta r} P_1}{2\pi N} = K \rho \rho N^2 D_p^5 (2-6)
\]

2. Inequality constraint

The propeller needs to satisfy the requirement of cavitation, which is derived from Keller's formula:

\[
1.3 + 0.3Z \frac{1}{2} \rho (P_r - P_a) D_f + K = (A_\alpha / A_\beta)_{\min} (2-7)
\]

Then, the inequality constraint condition is:

\[
1.3 + 0.3Z \frac{1}{2} \rho (P_r - P_a) D_f + K = (A_\alpha / A_\beta)_{\min} (2-7)
\]

In the formula: the static pressure at the center of propeller shaft is \( P_r \); the vaporization pressure of sea water at 15 degrees Celsius is \( P_v \); the thrust of propeller is \( T_r \); the blade number of propeller is \( Z \); the constant is \( K \), the fast boat is 0, others, twin-propeller boats are 0.1, and the single-propeller boat is 0.2.

According to the ship code, Initial stability height \( GM > 0.7m \)

Rolling cycle:

\[
T_1 = 1.05B / \sqrt{GM} < 6.0 (2-9)
\]

E. Optimize the total objective function

The objective functions of the three subsystems of speediness, maneuverability and seakeeping of UAV are synthesized, and the general objective function is \( f(x) \) constructed in the form of power exponential product as follows:

\[
f(x) = f_1(x)^{a_1} \cdot f_2(x)^{a_2} \cdot f_3(x)^{a_3} (2-10)
\]

In the formula: \( a_1, a_2, a_3 \) are weights of rapidity, maneuverability and Seakeeping respectively. In the form of product sum \( a_1 \times a_2 \times a_3 = 1 \), this paper needs to optimize the value of the total objective function [7] \( f(x) \) as large as possible.

III. ANALYSIS OF GENETIC ALGORITHMS

A. Introduction of Genetic Algorithms

The basic idea of genetic algorithm is mainly derived from Darwin's evolutionism, which is an algorithm formed by simulating the biological inheritance and evolutionary mechanism in nature. Its principle is to produce better individuals according to the mechanism of eliminating the fittest. In the algorithm, according to the fitness value of the individual in the problem, the selected individuals are inherited to the next generation by certain rules, and the selected individuals are randomly manipulated by crossover and mutation, thus generating a new population solution [8-9].

The steps of standard genetic algorithm are as follows: 1) Random initialization of population. 2) Calculate the fitness of each individual in the population. 3) When the optimal solution is found or the maximum genetic algebra is reached,
the algorithm is terminated, the loop is withdrawn and the optimal individual is output. 4) Otherwise, the roulette is selected according to the fitness value. 5) Cross and mutation operations. 6) Return to step 3. The flow chart of the algorithm is shown in Figure 3.1.

![Figure 3.1 flow chart of genetic algorithm](image)

**B. Parallel Strategy of Genetic Algorithms**

The genetic algorithm has good global search ability and can search all the solutions in the solution space quickly. But in practical application, genetic algorithm is prone to premature convergence. The premature problem is the problem of local convergence. In the process of optimization calculation, premature convergence and local optimum are not conducive to finding the optimal solution in the overall situation, and parallel strategy can alleviate such problems. Parallel strategy is to divide and parallel out multiple subspaces in the solution space of multiple variables, and then find the optimal solution sequentially in each subspace combination. If the parallel number is \( P \), the interval of each variable is divided into \( P \) (see Figure 3.2). For \( N \) design variables, the interval of optimization calculation has \( PN \) combinations. If the number of optimization calculation is \( M \) times, the number of calculation of the whole optimization system is \( M \times PN \) times.

![Figure 3.2 parallel thinking](image)

\[
P \quad 1 \quad 2 \quad \cdots \quad \cdots \quad \cdots \quad N \quad \text{ (variable intervals)}
\]

**C. Introduction to optimization software**

The composition of the whole software includes the following Windows: the software enters the interface (FIG. 3.3), the main operation window (FIG. 3.4), the weight setting window (FIG. 3.5), the penalty factor setting window (FIG. 3.6), the upper and lower limit setting window of design variables (FIG. 3.7), and the calculation interface of each algorithm (FIG. 3.8).

IV. EXPLORE SENSITIVE VARIABLES

By applying parallel strategy to genetic algorithm, the
problem of local optimum can be solved. The key to parallel
design is to find sensitive variables. For small waterplane
catamarans, in the design variables selected in this paper.
According to experience, Loa L, design speed Vs and
propeller diameter Dp are three variables that are more
sensitive to the objective function. The main work of this
paper is to find the most sensitive variable to the objective
function among these three variables, which will provide help
for the parallel design of genetic algorithm.

The initial settings and optimum values of each variable are as
follows.

| Variable                      | Lower limit of variables | Upper limit of variables | Optimization value |
|-------------------------------|--------------------------|--------------------------|--------------------|
| Submergence length Lh(m)     | 7                        | 7.3                      | 7.187              |
| Prop length Ls(m)            | 6.3                      | 6.6                      | 6.349              |
| Submersible radius Di(m)     | 0.7                      | 0.8                      | 0.783              |
| Pillar offset dl(m)          | 0                        | 0                        | 0                  |
| Loa L (m)                    | 7.8                      | 8.1                      | 8.083              |
| Type width B (m)             | 3.7                      | 3.85                     | 3.715              |
| Draught T(m)                | 0.9                      | 1.15                     | 0.908              |
| Block coefficient Cb(m)      | 0.2                      | 0.232                    | 0.222              |
| Longitudinal center on buoyancy Leb | -0.1                | 0.1                      | 0.086              |
| Propeller diameter dp        | 0.84                     | 0.85                     | 0.847              |
| Area ratio Aeo               | 0.4                      | 0.45                     | 0.447              |
| Pitch ratio Pdp              | 1.1                      | 1.15                     | 1.126              |
| Propeller speed N(r/min)     | 270                      | 350                      | 279.22             |
| Design speed Vs(kn)          | 7.5                      | 8.2                      | 7.994              |
| Segment spacing c0(m)        | 2.95                     | 3.15                     | 3.085              |
| Line length Lw(m)            | 6.3                      | 6.6                      | 6.38               |
| Submerged area of bow Ab     | 2                        | 3                        | 2.204              |
| The center of gravity height Zg(m) | 1.54            | 1.6                      | 1.583              |
| Waterplane coefficient Cw    | 0.145                    | 0.155                    | 0.152              |

Table 4-1 upper and lower limits of initial design variables
and optimization table

The process of finding sensitive variables is as follows:
The interval of other variables is controlled unchanged. The
Loa L is divided into the following seven intervals for
optimization. The interval and the corresponding function
value a are shown in Table 4-2. The trend of variation is
shown in Figure 4-1 below.

As can be seen, when the value of variable Loa L is in the
interval [7.8-8.05]. The total objective function shows an
increasing trend and reaches its maximum value at
[8.05-8.05]. In the following interval [8.05-8.1], the value of
the total objective function decreases. Therefore, when the
Loa is within the interval [7.8.8.1], it is the best choice to take
the value of Loa around 8.05 to optimize the value of the total
objective function.

The interval of other variables is controlled unchanged.
Controlling other variable intervals unchanged, the design
speed Vs is divided into the following seven intervals for optimization.
The interval and the corresponding function value b are shown in Table 4-3. The trend of
variation is shown in Figure 4-2 below.

By analyzing the trend chart, it can be seen that when the
variable design speed Vs value is within the range [7.5-8.2],
the value of the total objective function shows a decreasing
trend, and the decreasing trend is stable. Therefore, when the
design speed Vs value is within the range [7.5-8.2],
controlling its value around 7.5 is most conducive to the
optimization of the value of the total objective function.
Controlling other variable intervals unchanged, the propeller
diameter Dp is divided into the following seven intervals for
optimization. The intervals and corresponding function
values c are shown in Table 4-4, and the trend of variation is
shown in Figure 4-3 below.
It can be seen from the analysis of the trend chart that when the variable propeller diameter value is within the interval [0.840-0.850], the total objective function value within the interval [0.84-0.844] presents an increasing trend and the increasing trend is stable. In the interval [0.844-0.850], the value of the total objective function generally shows a decreasing trend, but the decreasing trend is unstable. Therefore, when the propeller diameter value is within the range of [0.840-0.850], the control value around 0.844 is most conducive to the optimization of the total objective function value.

The results of each step are as follows:

- Sensitivity of Loa:
  \[ \Delta \text{Lr} = \frac{(a_{\text{max}} - a_{\text{min}})}{a_{\text{min}}} \times 100\% = 12.12\% \]

- Sensitivity of design speed:
  \[ \Delta \text{Vs} = \frac{(b_{\text{max}} - b_{\text{min}})}{b_{\text{max}}} \times 100\% = 16.53\% \]

- Sensitivity of propeller diameter:
  \[ \Delta \text{Dp} = \frac{(c_{\text{max}} - c_{\text{min}})}{c_{\text{max}}} \times 100\% = 2.56\% \]

V. CONCLUSION

Sensitivity analysis was carried out on the three variables that had a great impact on the catamaran with small waterplane, namely, Loa, designed speed and propeller diameter. The following conclusions are drawn:

a. In the comprehensive optimization of small waterplane catamaran with genetic algorithm, the sensitivity of Loa L, design speed Vs and propeller diameter Dp are 12.12%, 16.53% and 2.56%, respectively.

b. Among the three variables of Loa L, design speed Vs and propeller diameter Dp, the one that has the greatest influence on the objective function is design speed Vs.
