Two Open Universes Connected by a Wormhole: 
Exact Solutions

Abstract

In this paper I present a spacetime of two open universes connected by a Lorentzian wormhole. The spacetime has the following features: (1) It can exactly solve the Einstein equations; (2) The weak energy condition is satisfied everywhere; (3) It has a topology of $R^2 \times T_g$ ($g \geq 2$); (4) It has no event horizons.

Key words: topology, wormhole, cosmology
Wormholes (or quantum foams) could play important roles on both microscopic and macroscopic scales in the realm of classical and quantum gravity [1, 2, 3, 4]. Field lines trapped in wormholes have led to the concepts of “mass without mass” and “charge without charge” [1, 2]. In the context of Euclidean quantum gravity, Euclidean wormholes arise from topology change on the Planckian scales, which have been proposed to cause the loss of quantum coherence or to fix coupling constants [3, 4]. (However, see the recent discussions of Hawking [5].) More interestingly, Morris, Thorne, and Yurtsever [6] (see also Novikov [7]) have shown that a Lorentzian wormhole can be transformed into a time machine (i.e., a spacetime with closed timelike curves). Morris and Thorne [8] have also considered the possibility of using Lorentzian wormholes as tools for interstellar travel. Applications of wormholes in cosmology have also been investigated [9, 10].

In this paper I focus on Lorentzian wormholes, which are essentially the time-development of three-dimensional wormholes [11, 12]. Such kind of spacetimes exhibit wormhole structures on their spacelike foliations, the wormholes either connect one universe to another universe or connect one region to another distant region in the same universe. As far as I am aware, almost all of the Lorentzian wormhole solutions discovered in literatures have two-dimensional spacelike cross-sections with a topology of $S^2$. With very generic arguments, Morris and Thorne [8] have shown that for static, spherically symmetric, and traversable (i.e., having no event horizons) wormholes the weak energy condition must be violated near the wormhole throats. Dynamic (evolving) wormholes have also been considered [13, 14, 15, 16, 17, 18]. It has been demonstrated that dynamic wormholes without violation of the weak energy condition could exist within a finite period of time [13, 14]. In this paper, I present a wormhole spacetime whose two-dimensional spacelike cross-sections have a topology of $T_g$ ($g \geq 2$) instead of $S^2$ that is usually considered in literatures, where $T_g$ is a $g$-torus. I show that, the wormhole spacetime represents two open universes connected by a Lorentzian wormhole and has the following features: (1) It can exactly solve the Einstein equations; (2) The weak energy condition is satisfied everywhere; (3) It has a topology of $R^2 \times T_g$ ($g \geq 2$); (4) It has no event horizons.

The wormhole spacetime is constructed from a usual open Friedmann-Robertson-Walker (FRW) universe. An open FRW universe has negative spatial curvature and can be foliated
with spatial hyperbolic hypersurfaces \((H^3)\). Each \(H^3\) can be embedded in a four-dimensional Minkowski spacetime through \([19]\)

\[
T^2 - X^2 - Y^2 - Z^2 = a^2,
\]

where \((T, X, Y, Z)\) are the Cartesian coordinates in the Minkowski spacetime, \(a\) is a constant. (Throughout the paper I use the geometric units \(G = c = 1\).) The metric of the Minkowski spacetime is

\[
dS^2 = -dT^2 + dX^2 + dY^2 + dZ^2.
\]

Different \(H^3\) can have a different radius, thus \(a\) is a function of the cosmic time \(t\) which labels the spacelike foliation of the universe. Let’s cut an \(H^3\) at \(Z = \text{constant}\), then we obtain a two-dimensional hyperbolic surface \(H^2\) with a radius \((a^2 + Z^2)^{1/2}\). An \(H^2\) is a two-dimensional Lobachevskii space, which can be compactified through \(H^2/\Gamma\), where \(\Gamma\) is an isometric group without fixed points on \(H^2\). If we require manifolds to be orientable, then the only compact surfaces that can be obtained from \(H^2\) are \(g\)-tori \(T_g\) with \(g \geq 2\) being the genus (i.e., the number of holes) of the surfaces \([20, 21, 22]\). A \(T_g\) with \(g \geq 1\) can be obtained as the quotient of a polygon of \(4g\) sides with all vertices being identified with each other and the sides being identified in pairs \([21]\). Now let’s start with an open FRW universe and compactify its two-dimensional cross-section \(H^2\) to a \(T_g\) \((g \geq 2)\), then we obtain a spacetime \((M, g_{ab})\) which has the same metric as an ordinary open FRW universe but has a topology of \(M = R^2 \times T_g\) \((g \geq 2)\). [An ordinary open FRW universe, i.e. the covering space of \((M, g_{ab})\), has a topology of \(R \times H^3\).] I will show that the spacetime \((M, g_{ab})\) represents two open universes connected by an evolving Lorentzian wormhole.

The spacetime \((M, g_{ab})\) can be covered locally with coordinates \((t, \chi, \xi, \phi)\), where \(t\) is the cosmic time and \((\chi, \xi, \phi)\) are defined with \((T, X, Y, Z)\) through

\[
T = a \cosh \chi \cosh \xi,
\]

\[
X = a \cosh \chi \sinh \xi \cos \phi,
\]

\[
Y = a \cosh \chi \sinh \xi \sin \phi,
\]

\[
Z = a \sinh \chi.
\]
Then the FRW metric is given by
\[ ds^2 = -dt^2 + a(t)^2 \left[ d\chi^2 + \cosh^2 \chi \left( d\xi^2 + \sinh^2 \xi \, d\phi^2 \right) \right]. \] (7)

Consider the two-dimensional cross-section \( S = T_g(g \geq 2) \) with \( t = \text{constant} \) and \( \chi = \text{constant} \). The metric on \( S \) is
\[ d\bar{s}^2 = a^2 \cosh^2 \chi \left( d\xi^2 + \sinh^2 \xi \, d\phi^2 \right). \] (8)

According to the Gauss-Bonnet theorem, the area of \( S \) is \[ \mathcal{A} = 4\pi (g - 1)a^2 \cosh^2 \chi. \] (9)

Thus, the size of \( S \) is completely determined by its genus and the metric on it. On the hypersurface \( t = \text{constant} \), \( \mathcal{A} \) takes the minimum at \( \chi = 0 \): \( \mathcal{A}_{\text{min}} = 4\pi (g - 1)a^2 \) which is non-zero for \( g \geq 2 \). As \( \chi \to \pm \infty \), \( \mathcal{A} \to \infty \) exponentially and we enter two open universes (they are open since the hypersurface \( t = \text{constant} \) has uniform negative curvature everywhere).

Therefore, \((M, g_{ab})\) represents a spacetime of two open universes connected by a wormhole. One open universe is on the side with \( \chi > 0 \), the other is on the side with \( \chi < 0 \). The “throat” of the wormhole is at \( \chi = 0 \). Since \( a = a(t) \), the wormhole evolves with time.

The coordinate \( \chi \) measures the proper distance from the wormhole’s throat on the hypersurface \( t = \text{constant} \), which goes from \(-\infty \) to \( \infty \). Define \( r = \cosh \chi \), then the metric in Eq. (7) can be written as
\[ ds^2 = -dt^2 + a(t)^2 \left[ \frac{dr^2}{r^2 - 1} + r^2 \left( d\xi^2 + \sinh^2 \xi \, d\phi^2 \right) \right]. \] (10)

However, \( r > 1 \) covers only one side of the wormhole: either the region with \( \chi > 0 \), or the region with \( \chi < 0 \).

Since \((M, g_{ab})\) is locally isometric to an open FRW universe, it can exactly solve the Einstein equations with a suitable stress-energy tensor. Let’s take the stress-energy tensor to be that of a perfect fluid: \( T_{ab} = (\rho + p)u_a u_b + pg_{ab} \), where \( u^a = (\partial/\partial t)^a \) is the four-velocity of comoving observers, \( \rho = \rho(t) \) and \( p = p(t) \) are the energy density and pressure measured by comoving observers. Then for the metric in Eq. (7) the Einstein equations are reduced to the familiar forms for an open FRW universe
\[ \left( \frac{\dot{a}}{a} \right)^2 = \frac{8\pi}{3} \rho + \frac{1}{a^2} + \frac{\Lambda}{3}, \] (11)
\[ \frac{\ddot{a}}{a} = -\frac{4\pi}{3} (\rho + 3p) + \frac{\Lambda}{3}, \] (12)
where the dot denotes $d/dt$, $\Lambda$ is the cosmological constant. Supplied with a state equation $p = p(\rho)$, Eq. (11) and Eq. (12) can be solved. There are many exact solutions, here I list some of them [24]:

1) Vacuum solution: Let $\rho = p = \Lambda = 0$, then we have the simplest solution

$$a = t,$$  \hspace{1cm} (13)

which is locally a Milne universe.

2) Wormhole supported by dust: In such a case $p = 0$, $\Lambda = 0$, and $\rho a^3 = \text{constant} \equiv 3C_1/8\pi$. The solutions are

$$a = \frac{1}{2}C_1 (\cosh \eta - 1), \quad t = \frac{1}{2}C_1 (\sinh \eta - \eta),$$  \hspace{1cm} (14)

where $\eta > 0$ is a parameter.

3) Wormhole supported by radiation: In such a case $p = \rho/3$, $\Lambda = 0$, and $\rho a^4 = \text{constant} \equiv 3C_2/8\pi$. The solutions are

$$a = \left(t^2 + 2C_2^{1/2}t\right)^{1/2}.$$  \hspace{1cm} (15)

4) Wormhole supported by a cosmological constant: Suppose $\Lambda > 0$ and $\rho = p = 0$. Then we have the open de Sitter solutions

$$a = \left(\frac{3}{\Lambda}\right)^{1/2} \sinh \left[\left(\frac{\Lambda}{3}\right)^{1/2} t\right].$$  \hspace{1cm} (16)

These are inflating wormholes.

Since all these wormhole solutions are supported by ordinary matter (dust, radiation, or simply vacuum) or a positive cosmological constant, the weak energy condition (which requires $\rho \geq 0$ and $\rho + p \geq 0$) is satisfied throughout the wormhole spacetime. In fact, for the solutions in 1) 2) and 3), all energy conditions (the weak energy condition, the null energy condition, the dominant energy condition, the strong energy condition, etc [12, 19]) are satisfied all the time and everywhere.

All the solutions presented above are dynamic. If we let $\dot{a} = \ddot{a} = 0$ in Eq. (11) and Eq. (12), we get $\rho + p = -(4\pi a^2)^{-1} < 0$, so there are no static solutions satisfying the weak energy condition.
Since the weak energy condition is satisfied and the spatial curvature is negative, the wormhole spacetime constructed above expands forever if it expands initially. Such a wormhole spacetime has no event horizons and no singularities in the future, so an observer can travel from one side to the other if he travels to the future. Though the spacetime may have singularities in the past as in the big-bang case, there will be no problem if a time arrow exists as in our universe. The time arrow will forbid any observer and light ray from traveling to the past, then we only need to consider traveling to the future. [The solutions in 1) and 4) even do not have singularities in the past, any worldline in these solutions can be extended to the past infinitely.] In such a wormhole spacetime with a time arrow, an observer can travel from one side to the other. The observer will feel no tidal force since the space is homogeneous. In fact he will not feel any difference in local spatial geometry from the place where he starts. If $\rho \geq 0$ and $\Lambda \geq 0$ — as in the cases for our solutions, the observer even will not feel the existence of the “throat”, since the wormhole expands so rapidly that as the observer passes through the wormhole to the other side he always sees that the cross-section $\mathcal{S}$ gets larger and larger. To see this, let’s consider a bunch of light rays passing through the wormhole. Suppose the light rays travel in such a way that at any moment their velocity is perpendicular to $\mathcal{S}$, i.e., along every light ray we have $\xi = \text{constant}$ and $\phi = \text{constant}$. (This can be realized due to the symmetry of the spacetime.) Let’s take the tangent vector of the null geodesics of the light rays to be

$$k^a = \frac{1}{a} \left[ \left( \frac{\partial}{\partial t} \right)^a + \frac{1}{a} \left( \frac{\partial}{\partial \chi} \right)^a \right].$$

(17)

It can be checked that $k^a$ satisfies the affine geodetic equation $k^b \nabla_b k^a = 0$, so $\lambda$ is the affine parameter of the null geodesics if $k^a = (\partial / \partial \lambda)^a$. Further more, it can be shown that

$$\lambda = \int adt.$$  

(18)

The light rays form a null geodetic congruence orthogonal to $\mathcal{S}$. The expansion of the light rays, $\nabla_a k^a$, is related to the variation of $\mathcal{A}$ (the area of $\mathcal{S}$) along the light rays by $d\ln \mathcal{A}/d\lambda = \nabla_a k^a$ [11]. So we have

$$\frac{d\ln \mathcal{A}}{d\lambda} = \frac{2}{a^2} (\tanh \chi + \dot{a}).$$

(19)

Eq. (19) can also be obtained from Eq. (8) and Eq. (18) by using the fact that $d\chi = dt/a$ along the light rays. From Eq. (11), if $\rho$ and $\Lambda$ are non-negative, $a^2 \geq 1$ always. If $\dot{a} > 0$
which is true for the expanding solutions described above, we always have $\dot{a} \geq 1$. Since $\tanh \chi > -1$, we have $\tanh \chi + \dot{a} > 0$ all the time. So, along the light rays, $d \ln A/d\lambda$ is always positive. This must also be true for the observer since he can never travel faster than light: as the observer travels through the wormhole, he will see that the size of $\mathcal{S}$ keeps increasing.

Hochberg and Visser have demonstrated that violation of the null energy condition is a generic feature of all wormholes, no matter they are static or dynamic [25, 26]. (The null energy condition requires only $\rho + p \geq 0$, so the weak energy condition implies the null energy condition. In other words, if the null energy condition is violated the weak energy condition must be violated too.) Their arguments essentially rely on their definition of wormhole throats and their assumption that all wormholes have throats with their definition. They define a wormhole throat to be a marginally anti-trapped surface, which means that bundles of light rays that enter the wormhole at one mouth and emerge from the other must have cross-sectional areas that initially decrease and then increase [25, 8]. With this definition of throats, the wormhole spacetime constructed in this paper does not have a throat if $\rho$ and $\Lambda$ are non-negative, since bundles of light rays propagating through it always diverge. However, the spacetime I have constructed exhibits a well-defined wormhole structure with a well-defined throat (with the ordinary meaning [3, 8]) on the spatial hypersurface at any moment: two large spaces are connected by a narrow tube. My results do not conflict with the claim of Hochberg and Visser because their definition of wormhole throats does not apply to my case. This means that Hochberg and Visser's definition of wormhole throats cannot cover all kinds of wormhole spacetimes, there exist spacetimes which have unambiguous wormhole structures but do not have throats with Hochberg and Visser's definition. (A classical example of wormhole that cannot be covered by Hochberg and Visser's definition is the Einstein-Rosen bridge [27]. As bundles of light rays pass through the Einstein-Rosen bridge from one side, their cross-sectional areas keep decreasing until the light rays hit the future spacetime singularity.)

In summary, I have constructed a wormhole spacetime which has many nice features. The spacetime represents two open universes connected by a wormhole. Since more and more observations show that we are living in a universe with a low mass density, it is
quite possible that our universe is open (28, 29 and the references therein; certainly there is another possibility that we are living in a flat universe with a positive cosmological constant). Maybe one of the open universes in the wormhole spacetime I have constructed is just the universe that we are living in, at least there is no observational evidence to exclude this possibility! It would be interesting to investigate the fluctuations of the cosmic microwave background in such a wormhole spacetime to see if it is possible to tell if we are really living in such an open universe [30, 31]. The wormhole spacetime can exactly solve the Einstein equations with a stress-energy tensor satisfying the weak energy condition. The solutions presented in the paper are true solutions to the Einstein equations since we are aware of the matter contents required by these solutions, which are dust, radiation, vacuum, or a positive cosmological constant. In contrast, for most wormhole solutions in literatures (the Einstein-Rosen bridge is a prominent exception), a geometry is assumed and the stress-energy tensor is calculated from the metric by solving the Einstein equations reversely.

I am grateful to J. Richard Gott for helpful discussions. This work was supported by the NSF grant AST-9529120.
