Massless Dirac Fermions on a Space-Time Lattice with a Topologically Protected Dirac Cone

A. Donís Vela,* M. J. Pacholski,* G. Lemut,* J. Tworzydło,* and C. W. J. Beenakker*

The symmetries that protect massless Dirac fermions from a gap opening may become ineffectif if the Dirac equation is discretized in space and time, either because of scattering between multiple Dirac cones in the Brillouin zone (fermion doubling) or because of singularities at zone boundaries. Here we employ Dirac fermions on a space-time lattice that removes both obstructions is introduced. The quasi-energy band structure has a tangent dispersion with a single Dirac cone that cannot be gapped without breaking both time-reversal and chiral symmetries. It is shown that this topological protection is absent in the familiar single-cone discretization with a linear sawtooth dispersion, as a consequence of the fact that there the time-evolution operator is discontinuous at Brillouin zone boundaries.

1. Introduction

1.1. Objective

A 3D topological insulator has gapless surface states with a conical dispersion.[1,2] This Dirac cone is protected by Kramers degeneracy, no perturbation that preserves time-reversal symmetry can gap it out—provided that the top and bottom surfaces remain uncoupled, to prevent Dirac cones from annihilating pairwise.[3]

To study the dynamics of Dirac fermions on a computer, one needs to discrete the Dirac equation

\[ i\hbar \left( \begin{array}{cc} \partial_t + v \sigma \cdot \partial_r & \partial_t \\ \partial_t & - \partial_r \end{array} \right) \Psi(r, t) = V(r) \Psi(r, t) \] (1.1)

for the two-component spinor \( \Psi(r, t) \) (with velocity \( v \) and Pauli spin matrices \( \sigma \)). The electrostatic potential \( V \) preserves time-reversal symmetry, so one would expect the Dirac cone to remain gapless for any time-reversal invariant discretization scheme that avoids fermion doubling[4] (only zero-energy states at momentum \( k = 0 \)).

The objective of our paper is, first, to demonstrate that this expectation is incorrect, it does not apply to the split-operator technique[5] for the discretization of the time-evolution operator, which is commonly used[6–8] because of its computational efficiency. Then, second, we will show how a “drop-in” modification of the algorithm can restore a gapless Dirac cone — without reducing the computational efficiency (scaling as \( N \ln N \) in the number of lattice sites).

We consider a 2+1-dimensional space-time lattice with lattice constants \( a_0 \) in space and \( \delta t \) in time. In the split-operator technique the derivative operator \( d/dx \) is evaluated in momentum representation as the linear function \( k \) in the first Brillouin zone \(|k| < \pi/a_0 \) — periodically repeated as a sawtooth for larger momenta. The drop-in modification that we propose is to replace \( k \) by \((2/a_0) \tan(k/2)\). The computational efficiency of the algorithm is not compromised, but the effect on the quasi-energy–momentum band structure is crucially important: While the linear sawtooth dispersion introduces discontinuous derivatives at Brillouin zone boundaries, the tangent dispersion produces a smooth band structure, see Figure 1. As we will show, a potential that varies rapidly on the scale of \( a_0 \) is able to gap out the Dirac cone in the former case but not in the latter case.

By way of introduction, before we embark on the space-time discretization, we first discuss the simpler time-independent problem, when only space is discretized.

1.2. Time-Independent Problem

Consider a 1D lattice along the x-axis, and first take \( V \equiv 0 \). Different ways to discretize the derivative \( d/dx \) will produce different energy-momentum dispersion relations \( \pm E(k) \). (The \( \pm \) sign distinguishes the chirality of the massless Dirac fermions, left-movers versus right-movers.) What all dispersions have in common is that they are periodic with period \( 2\pi/a_0 \) and vanish linearly at \( k = 0 \). We compare three alternatives, see Figure 2.
Near \( \pi \) which vanishes also at the boundary \( \varepsilon \) produces a dispersion relation that is strictly ous Dirac cone at nonzero momentum. The so called “slac couples loulzone(fermiondouling).Anonlocaldiscretization,which givesasinedispersion (red and blue curves).

Three 1D dispersion relations, corresponding to a local discretization of the derivative operator \( \partial_x \) (black curve) and to two alter native nonlocal discretizations (red and blue curves).

The local discretization \( \partial_x \rightarrow [f(x+a_0)−f(x−a_0)]/(2a_0) \) gives a sine dispersion

\[
E_{\text{local}}(k) = \frac{\hbar v}{a_0} \sin(a_0 k) \tag{1.2}
\]

which vanishes also at the boundary \( |k| = \pi/a_0 \) of the first Brillouin zone (fermion doubling). A nonlocal discretization, which couples \( f(x) \) to distant lattice points, can remove the spurious Dirac cone at nonzero momentum. The so called “SLAC discretization”\(^9,10\) produces a dispersion relation that is strictly linear within the first Brillouin zone \( |k| < \pi/a_0 \). The dispersion has the \( 2\pi \)-periodic sawtooth form\(^11\)

\[
E_{\text{SLAC}}(k) = \frac{\hbar v}{a_0} \mod (a_0 k, 2\pi, -\pi) \tag{1.3}
\]

Now apply the staggered potential \( V(x) = V \cos(\pi x/a_0) \), switching from \( +V \) to \( -V \) between even and odd-numbered lattice sites. This potential couples the states at \( k \) and \( k + \pi/a_0 \), as described by the Hamiltonian

\[
H_\nu(k) = \begin{pmatrix} E(k) & V/2 \\ V/2 & E(k + \pi/a_0) \end{pmatrix} \tag{1.4}
\]

The Brillouin zone is halved to \( |k| < \pi/2a_0 \), with the band structure

\[
E_\nu(k) = \frac{1}{2} E(k) + \frac{1}{2} E(k + \pi/a_0) \pm \frac{1}{2} V^2 + \frac{1}{4} \sqrt{2} V^2 + [E(k) - E(k + \pi/a_0)]^2 \tag{1.5}
\]

A gap opens in the Dirac cone for both the local and SLAC discretizations, of size

\[
\delta E_{\text{local}} = V, \quad \delta E_{\text{SLAC}} = \frac{V^2a_0}{2\pi \hbar v} + O(V^4) \tag{1.6}
\]

What we learn from this simple calculation is that removing the second cone at \( |k| = \pi/a_0 \) is not enough to protect the Dirac cone at \( k = 0 \) from becoming gapped if the potential varies rapidly on the scale of the lattice constant. What happens is that the large gap \( \Delta \) in the dispersion at \( k = \pi/a_0 \) is folded onto \( k = 0 \) by the staggered potential, resulting in a minigap \( \delta E = V^2/\Delta \) for \( V \ll \Delta \). To avoid the gap opening we thus need a pole \( \Delta \rightarrow \infty \) in the dispersion at the Brillouin zone boundary.

An alternative discretization due to Stacey\(^12\) gives the dispersion

\[
E(k) = (2\hbar v/a_0) \tan(a_0 k/2) \tag{1.7}
\]

with a pole at \( k = \pi/a_0 \). And indeed, substitution of Equation (1.7) into Equation (1.5) shows that no gap opens at \( k = 0 \) (see Figure 3).

The merits of the Stacey discretization for the time-independent problem were studied in ref. [13] (at the level of the scattering matrix) and in ref. [14] (at the level of the Hamiltonian). It was shown that the eigenvalue equation \( H\Psi = E\Psi \) can be discretized into a generalized eigenvalue problem \( H\Psi = E\Psi \) with local Hermitian tight-binding operators on both sides of the equation.\(^4,15\) Basically, a local formulation of the generalized eigenvalue problem is possible because tangent is the ratio of sine and cosine, which represent local tight-binding operators on a lattice. If all one would care about would be the presence of a pole in the dispersion at \( k = \pi/a_0 \), one could work with other functions than the tangent, but the tangent dispersion combines this property with the possibility of a local algorithm.

1.3 Outline

So much for the introduction to the time-independent discretization. In what follows we turn to the dynamical problem, by generalizing the approach of refs. [12–14] to the discretization of space and time. In the next Section 2 we show that the time discretization removes the pole in the tangent dispersion, which becomes
a smooth function of momentum \( k \) and quasi-energy \( \epsilon \) (yellow bands in Figure 1). In Section 3 we then prove that the Dirac point remains gapless for any perturbation that preserves either time-reversal symmetry or chiral symmetry—even if it varies rapidly on the scale of the lattice constant.

In contrast, the quasi-energy bandstructure of the linear sawtooth dispersion has discontinuous derivatives at the Brillouin zone boundaries (red bands in Figure 1). These spoil the protection of the Dirac cone, which is gapped by a staggered potential.

A key feature of the approach presented in Section 2 is that it requires only a small modification of the usual split-operator technique, involving the replacement of the linear momentum operator appearing in the time-evolution operator by its tangent. Since this operator is evaluated in momentum representation, the replacement is immediate. It does not degrade the computational efficiency of the algorithm, which retains the favorable \( N \ln N \) scaling in the number of lattice sites (limited only by the efficiency of the fast Fourier transform).

An alternative implementation which is fully in real space is possible, taking the form of an implicit finite-difference equation \( A \Psi(t + \delta t) = B \Psi(t) \) with sparse matrices \( A \) and \( B \). This formulation is a bit more cumbersome to explain, we present it in Appendix.

2. Space-Time Discretization without Zone Boundary Discontinuities

2.1. Split-Operator Technique

The Dirac Hamiltonian

\[
H = v k \cdot \sigma + V(r)
\]  

(2.1)

is the sum of a kinetic term that depends on momentum \( k \) and a potential term that depends on position \( r \). (We set \( \hbar \) to unity.) The split-operator technique\(^{[5]}\) separates these two terms in the time-evolution operator,

\[
\Psi(t + \delta t) = e^{-iH\delta t} \Psi(t), \quad e^{-iH\delta t} = U + \mathcal{O}(\delta t)^3
\]  

(2.2)

with an error term that is of third order in the time slice \( \delta t \).\(^{[16]}\)

Space is discretized on a square or cubic lattice (lattice constant \( a_0 \) in each direction). The periodicity of the Brillouin zone is enforced by the substitution

\[
k \cdot \sigma \mapsto a_0^{-1} \sum \sigma \mod (a_0 k_x, 2\pi, -\pi)
\]  

(2.3)

In 1D this is the linear sawtooth dispersion of Figure 2, red curve. A discrete fast Fourier transform is inserted between the kinetic and potential terms, so that each is evaluated in the basis where the operators \( k \) and \( r \) are diagonal. The computational cost scales as \( N \ln N \) for \( N \) lattice sites.

The eigenvalues \( e^{i\epsilon} \) of the unitary operator \( U \) define the quasi-energies \( \epsilon \) modulo \( 2\pi/\delta t \). For free motion, \( V = 0 \), these are given by

\[
(\epsilon + 2\pi n/\delta t)^2 = v^2 \sum k_n^2, \quad n \in \mathbb{Z}, \quad |k_n| < \pi/a_0
\]  

(2.4)

The 2+1 dimensional band structure in the first Brillouin zone

\[
B = \{ k_x, k_y, \epsilon | -\pi < \epsilon < \pi, k_x, k_y, a_0 < \pi \}
\]  

(2.5)

is plotted in Figure 4 for \( v = a_0/\delta t \), when the dispersion is strictly linear along the \( k_x \) and \( k_y \)-axes. (Alternatively, for \( v = 2^{-1/2} a_0/\delta t \)}
The corresponding plots are in Appendix A.}

The band structure repeats periodically upon translation by ±2π/a0 in the kx, ky directions and by ±2π/δt in the ε direction. Upon crossing a zone boundary the dispersion has a discontinuous derivative, see Figure 5.

2.2. Smooth Zone Boundary Crossings

To remove the discontinuity at the Brillouin zone boundary we modify the kinetic term in the evolution operator (Equation (2.2)) in two ways: First we approximate the exponent by a rational function (Cayley transform\(^{17,18}\)),

\[
e^{\text{i}v0\delta t} = \frac{1 - \frac{1}{2} \text{i} v0 \delta t \cdot \sigma}{1 + \frac{1}{2} \text{i} v0 \delta t \cdot \sigma} + \mathcal{O}(\delta t^3) \tag{2.6}
\]

The error of third order in the time slice is of the same order as the error in the operator splitting, Equation (2.2).

Second we replace kx by (2/a0) tan(a0kx/2), defining the modified evolution operator

\[
\tilde{U} = e^{-\text{i}v0\delta t/2} \sum_n \sigma_a \tan(a0k_n/2) e^{\text{i}v0\delta t/2} \tag{2.7a}
\]

The inverse of the sum of Pauli matrices can be worked out, resulting in

\[
\tilde{U} = e^{-\text{i}v0\delta t/2} \left[ 1 - \sum_n \chi^2(k_n) \sigma_0 \right] - 2i \sum_n \sigma_a \chi(k_n) e^{-\text{i}v0\delta t/2} \tag{2.7b}
\]

We abbreviated \(\chi(k) = (v0\delta t/a0) \tan(a0k/2)\) and \(\sigma_0\) is the 2 × 2 unit matrix. This looks more complicated than Equation (2.2), but it can be computed equally efficiently since in both equations each operator is evaluated in the basis where it is diagonal.

The required periodicity when kx = kx + 2π/a0 is automatically ensured by the replacement of the linear momentum by the tangent, it does not need to be enforced by hand as in Equation (2.3). Although \(\tan(a0k_n/2)\) has a pole when \(k_n = \pi/a0\), this pole is removed in the evolution operator (2.7) — which has no singularity at the Brillouin zone boundaries.

The eigenvalues \(e^{\text{i}v0\delta t}\) of \(\tilde{U}\) for free motion, \(V = 0\), are given by

\[
\tan^2(\v0\delta t/2) = (v0\delta t/a0)^2 \sum_n \tan^2(a0k_n/2) \tag{2.8}
\]

plotted in Figures 6 and 7. Comparison with Figures 4 and 5 show that the zone boundaries are now joined smoothly. The dispersion is approximately linear near k = 0 and exactly linear along the lines kx = 0 and ky = 0 if we choose the discretization units such that v = a0/δt. (See Appendix A for the case \(v = 2^{-1/2} a0/\delta t\), when the linear dispersion is along \(k_n = \pm k_0\).)

3. Stability of the Dirac Point

3.1. Protection by Time-Reversal Symmetry

The condition of time-reversal symmetry for the unitary evolution operator U reads

\[
\sigma_1 U^\dagger \sigma_1 = U^{-1} \tag{3.1}
\]

Figure 5. Cut through the bandstructure of Figure 4 along the line \(k_x = k_y \equiv k\) (left panel) and along the kx-axis (right panel). In the former direction the dispersion has a discontinuous slope at the Brillouin zone boundaries (dotted lines).

Figure 6. Same as Figure 4, but now for the modified evolution operator (Equation (2.7)) (with v0/δt = 1).

Figure 7. Cut through the bandstructure of Figure 6 along the line \(k_x = k_y \equiv k\) (left panel) and along the ky-axis (right panel). In all directions the dispersion smoothly crosses the Brillouin zone boundaries (dotted lines).
where the complex conjugation should be taken in the real space representation, when \( k = -i\nabla \) changes sign. The time-reversal operator, \( \sigma_y \times \text{complex conjugation} \), squares to \(-1\), so Kramers theorem applies: In the presence of a periodic potential \( V \), when momentum \( k \) remains a good quantum number, the eigenvalues at \( k = 0 \) should be at least doubly degenerate.\(^{[19]}\)

Kramers degeneracy implies a band crossing at \( k = 0 \) — provided that the bands depend smoothly on \( k \) — hence this applies to the evolution operator \( \hat{U} \) for the tangent dispersion, but not to the operator \( U \) for the linear sawtooth dispersion. We conclude that the Dirac point of \( \hat{U} \) is protected by time-reversal symmetry, while the Dirac point of \( U \) is not.

We demonstrate this difference for the checkerboard potential

\[
V(x, y) = V \cos(\pi/a_0 x + \pi/a_0 y)
\]  

(3.2)

(The calculation is described in Appendix B.) In Figure 8 we show the three ways in which this potential can affect the Dirac point. The evolution operator \( \hat{U} \) shows the modification \( T_0 \), while \( U \) shows \( T_- \), see Figure 9. The other option \( T_+ \) appears in Figure 3 and in Appendix A.

### 3.2. Protection by Chiral Symmetry

Chiral symmetry of the evolution operator is expressed by

\[
\sigma_z U \sigma_z = U^{-1}
\]

(3.3)

Since \( U^{-1} = U^\dagger \), this implies that \( U \) can be decomposed in the block form

\[
U = \begin{pmatrix} A & B \\ -B^\dagger & C \end{pmatrix}, \quad A = A^\dagger, \quad C = C^\dagger
\]

(3.4)

We consider a 2D periodic potential, so that momentum \( k = (k_x, k_y) \) is a good quantum number. The band structure has winding number\(^{[20]}\)

\[
W = \frac{1}{2\pi} \text{Im} \oint \Gamma \, dk \cdot \partial_k \ln \det B(k) \in \mathbb{Z}
\]

(3.5)

Figure 8. Top row: Dirac point in the quasi-energy dispersion \( \varepsilon(k) \). Bottom row: Three topologically distinct modifications of the dispersion by the checkerboard potential. Only the Dirac point preserving modification \( T_0 \) is allowed for an evolution operator that depends smoothly on momentum.

Figure 9. Quasi-energy bandstructure for the evolution operators a),c) \( U \) and b),d) \( \hat{U} \) in the presence of the 2D checkerboard potential (Equation (3.2)) (for \( V = 2/\delta t = 2 v/a_0 \)). Panels c,d show a cut through the bandstructure for \( k_x = k_y = k \).
along a contour $\Gamma$ in the Brillouin zone on which $\det B$ does not vanish.[20,21] This is a topological invariant, it cannot change in response to a continuous perturbation.[22] A Dirac point within the contour is signaled by $W = \pm 1$. While pairs of Dirac points of opposite winding number can annihilate, a single Dirac point is protected by chiral symmetry—provided that the evolution operator is continuous.

The 2D Dirac Hamiltonian has chiral symmetry when $V \equiv 0$. An in-plane magnetization

$$M(x, y) = \mu_x (x, y) \sigma_x + \mu_y (x, y) \sigma_y$$

(3.6)

preserves the chiral symmetry. We are thus led to compare the two evolution operators

$$U = e^{-iM(x, y)\delta t/2} e^{-i\delta t/\alpha_0} \sum_{\sigma=\alpha,\beta} \sigma_a \alpha \mod (\alpha_0 k, 2\pi x - \delta t) e^{-iM(x, y)\delta t/2}$$

(3.7)

$$\bar{U} = e^{-iM(x, y)\delta t/2} \frac{1 - i(\alpha_0 \delta t/\alpha_0)}{1 + i(\alpha_0 \delta t/\alpha_0)} \sum_{\sigma=\alpha,\beta} \sigma_a \alpha \mod (\alpha_0 k, 2\pi x - \delta t) e^{-iM(x, y)\delta t/2}$$

(3.8)

Both satisfy the chiral symmetry relation, Equation (3.3), $\bar{U}$ is a continuous function of $k$ while $U$ is not.

The implication for the stability of the Dirac point is shown in Figure 10, where we compare the bandstructure in the presence of the checkerboard magnetization

$$M(x, y) = \mu \sigma_x \cos(\pi/\alpha_0 (x + y))$$

(3.9)

(see Appendix B). A gap opens for $U$ (linear sawtooth dispersion), while the Dirac point for $\bar{U}$ (tangent dispersion) remains unaffected.

4. Conclusion

In conclusion, we have presented a method to cure a fundamental deficiency of the split-operator technique for the space-time discretization of the Dirac equation.[5] The linear sawtooth representation of the momentum operator preserves the time-reversal and chiral symmetries of the continuum limit, but it breaks the topological protection of the Dirac cone that these symmetries should provide. The deficiency originates from the discontinuity of the discretized time-evolution operator at the boundaries of the Brillouin zone. We have demonstrated the breakdown of the topological protection for a simple model: a periodic potential (or magnetization) on a 2D square lattice (lattice constant $a_0$) which couples the Dirac point at $k = 0$ to the zone boundaries at $k = \pi/a_0$.

To restore the topological protection we modify the split-operator technique without compromising its computational efficiency, basically by replacing $a_0 k$ in the evolution operator by $2 \tan(a_0 k/2)$. Since the momentum operators are evaluated in the basis where they are diagonal, this is a “drop-in” replacement — it does not degrade the $N \ln N$ efficiency of the split-operator algorithm.

One open problem of the split-operator technique that is not addressed by our modification is the difficulty to incorporate the vector potential in a gauge invariant way.[21] For that purpose it would be useful to formulate the split-operator technique fully in real space. This is done in ref. [8] for the original approach with the linear sawtooth momentum operator. In Appendix C we show that our tangent modification also allows for a real space formulation.

The availability of a single-cone discretization scheme which is efficient and which does not break the topological protection is a powerful tool for dynamical studies of massless Dirac fermions. One application to Klein tunneling has been published recently.[24]

Appendix A: Bandstructures for $\nu = 2^{-1/2} a_0/\delta t$

The bandstructures in the main text are for space-time discretization units such that $\nu = a_0/\delta t$, when the dispersion is strictly linear along the lines $k_x = 0$ and $k_y = 0$. Alternatively, one can have a strictly linear...
dispersion along the diagonals \(k_x = \pm k_y\), by choosing \(v = 2^{-1/2} a_0/\delta t\). The bandstructures of \(U\) and \(\tilde{U}\) for free evolution are shown in Figure A1.

For \(v = 2^{-1/2} a_0/\delta t\) the checkerboard potential in the main text varies along the diagonals where \(U\) is continuous, so it does not affect the Dirac point. Instead we choose here a staggered potential \(V(x, y) = V \cos(x/a_0)\) that varies along the \(x\)-axis. (In Equation (B2) we thus replace \((k_x + \pi, k_y + \pi)\) by \((k_x + \pi, k_y)\).) The effect on \(U\) is the \(T_\delta\) gap-opening process of Figure 8, while the Dirac point of \(\tilde{U}\) is unaffected, see Figure A2.

We can also take the staggered magnetization \(M(x, y) = \mu \sigma_x \cos[(\pi/\alpha_0)x]\), with bandstructures very similar to those in Figure A2.

Appendix B: Bandstructure in the Checkerboard Potential

In this appendix we choose \(v = a_0/\delta t\) and set the discretization units \(a_0, \delta t\) to unity. We compute the eigenvalues of the evolution operators \(U\) and \(\tilde{U}\) in the presence of the 2D checkerboard potential \(V(x, y) = V \cos(x + y)\). This potential couples states at \((k_x, k_y)\) and \((k_x + \pi, k_y + \pi)\) with amplitude \(V/2\).

We denote by \(U_0(k)\) and \(\tilde{U}_0(k)\) the free evolution operators, for \(V = 0\), given by

\[
U_0(k) = \exp \left( \sum_{\alpha} \alpha \sigma_{\alpha} \right) \quad \text{(B1a)}
\]

\[
\tilde{U}_0(k) = \frac{1 - i \sum_{\alpha} \alpha \sigma_{\alpha} \tan(k_{\alpha}/2)}{1 + i \sum_{\alpha} \alpha \sigma_{\alpha} \tan(k_{\alpha}/2)} \quad \text{(B1b)}
\]

The quasi-energies \(\varepsilon^k\) are the eigenvalues of the \(4 \times 4\) matrices

\[
U^\prime = \begin{pmatrix} U_0(k_x, k_y) \varepsilon & 0 \\ 0 & U_0(k_x + \pi, k_y) \varepsilon \end{pmatrix} \quad \text{(B2a)}
\]

\[
\tilde{U}^\prime = \begin{pmatrix} \tilde{U}_0(k_x, k_y) \varepsilon & 0 \\ 0 & \tilde{U}_0(k_x + \pi, k_y) \varepsilon \end{pmatrix} \quad \text{(B2b)}
\]

The \(2 \times 2\) blocks at \((k_x, k_y)\) and \((k_x + \pi, k_y + \pi)\) are coupled by the matrix

\[
V = \exp \left[ -\frac{i}{2} \begin{pmatrix} V/2 & 0 \\ 0 & -V/2 \end{pmatrix} \right] = \begin{pmatrix} \cos(V/4) & -i \sin(V/4) \\ i \sin(V/4) & \cos(V/4) \end{pmatrix} \quad \text{(B3)}
\]

Results for \(V = 2\) are plotted in Figure 9.

Figure A1. Free evolution \((V = 0)\) bandstructures of \(U\) (left panel) and of \(\tilde{U}\) (right panel), for \(v = 2^{-1/2} a_0/\delta t\).

Figure A2. Same as Figure A1, but now in the presence of the potential \(V(x, y) = V \cos(x/a_0)\) with \(V = 2 \delta t\). The bandstructures for the staggered magnetization \(M(x, y) = \mu \sigma_x \cos[(\pi/\alpha_0)x]\) look very similar.
For $U$, the Dirac point at $k = 0$ is not affected by the checkerboard potential. In contrast, for $U'$ the $T_c$ modification of Figure 8 replaces the band crossing at $k = 0$ by four band crossings at $\pm(q, q)$ and $\pm(q, -q)$, with

$$
\cos \left( \frac{\pi - 2q}{\sqrt{2}} \right) = \cos \left( \frac{\pi}{\sqrt{2}} \right) \cos (V/2) \Rightarrow q = 0.067 V^2 + O(V^4) \quad (B4)
$$

The calculation for a checkerboard magnetization $M(x, y) = (\mu_x \sigma_x + \mu_y \sigma_y) \cos(x + y)$ proceeds entirely similar, upon replacement of $V'$ by $\mathcal{M} = \exp \left[ \frac{-i}{4} \begin{pmatrix} 0 & \mu_x - i \mu_y \\ \mu_x + i \mu_y & 0 \end{pmatrix} \right] \quad (B5)

The band structure for $\mathcal{M}$ is shown in Figure 10. For evolution operator $U'$ the spectrum acquires a gap $\Delta \epsilon = 0.095 V^2 + O(V^4)$. For $U$ the Dirac cone remains gapless.

**Appendix C: Real-Space Formulation of the Split-Operator Discretized Evolution Operator**

**C.1. Implicit Finite-Difference Equation**

The discretized Dirac equation for the tangent dispersion, $\Psi(t + \delta t) = U \Psi(t)$ with $U$ given by Equation (2.7), can be rewritten as a local implicit finite-difference equation in real space—without requiring a Fourier transform to momentum space.

We introduce the translation operator $r_a \rightarrow r_x + a_0$ on a square or cubic lattice, given by $T_a = e^{i \alpha a_0}$, with $\alpha = \partial / \partial r_a = i \hbar \sigma_a$. We note the identity

$$
i \tan(a_k a_x/2) = \frac{T_x - 1}{T_x + 1} \quad (C1)
$$

The product operators

$$
D_0 = \frac{1}{4} \prod_a (T_a + 1), \quad D_a = \frac{1}{2} (T_a - 1) \prod_{a' \neq a} (T_{a'} + 1) \quad (C2)
$$

couple nearby sites on the lattice.

The split-operator evolution equation

$$
\Psi(t + \delta t) = e^{-i V(1/\delta t)/2} \frac{1 - i (\nu \delta t/a_0)}{1 + i (\nu \delta t/a_0)} \sum_a \sigma_a \tan(a_k a_x/2) e^{-i V(1/\delta t)/2} \Psi(t) \quad (C3)
$$

can be rewritten identically in terms of these local operators,

$$
\left( D_0 + \frac{\nu \delta t}{2 a_0} \sum_a \sigma_a D_a \right) e^{i V(1/\delta t)/2} \Psi(t + \delta t)
$$

$$
= \left( D_0 - \frac{\nu \delta t}{2 a_0} \sum_a \sigma_a D_a \right) e^{-i V(1/\delta t)/2} \Psi(t) \quad (C4)
$$

The finite-difference equation (C4) of the form $A \Psi(t + \delta t) = B \Psi(t)$ is called “implicit,” because one needs to solve for the unknown $\Psi(t + \delta t)$ given the known $\Psi(t)$. The matrices $A$ and $B$ are both sparse, each of the $N$ sites on the 2D square lattice is only coupled to its four nearest neighbors. The method of nested dissection then allows for an efficient solution of the finite difference equation [25-27]. There is an initial $N^{3/2}$ overhead from the LU decomposition of the matrix $A$, but subsequently the computational cost per time step scales as $N \ln N$ with the number of lattice sites, which is the same scaling as the split-operator algorithm.

**C.2. Computational Efficiency**

To check the efficiency of the discretization schemes we have calculated [28] the spreading of a wave packet in a 2D disordered lattice (of $M \times M$ sites, with periodic boundary conditions in $x$- and $y$-directions). We take a random potential $V(x, y)$ which varies independently on each of the $N = M^2$ sites, uniformly in the interval $(-0.5, 0.5) \times \hbar v / a_0$. The initial state is

$$
\Psi(x, y, 0) = \left[ 4\pi u^2 \right]^{-1/2} e^{i k_0 x} e^{-(x^2 + y^2)/2u^2} \left[ \begin{array}{c} 1 \\ 1 \end{array} \right] \quad (C5)
$$

with parameters $k_0 = 0.5 \ h v / a_0, w = 30 a_0$. We follow the time evolution for $T = 10^3$ time steps $\delta t = 2^{-12} a_0 / 4\hbar$.

Figure C1. Demonstration of the favorable $N \ln N$ scaling with the number $N$ of lattice points of the single-cone discretization scheme with the tangent dispersion. The plot at the left shows the run time $t_{\text{evolution}}$ per time step for the evolution of the wave packet (Equation (C5)) through a disordered 2D system: red symbols for the split-operator approach, blue symbols for the implicit finite-difference approach. The latter approach has an initial overhead $t_{\text{initial}} \propto N^{3/2}$ from the LU decomposition, shown in the right plot.
We compare the run time of the finite-difference code for a range of values of $N$, distinguishing the time $t_{\text{initial}}$ spent on the initial LU decomposition from the run time $t_{\text{evolution}}$ per time step needed for the subsequent evolution of the wave packet. (The full run time of the code is $t_{\text{initial}} + t_{\text{evolution}}$.)

The data shown in Figure C1 is consistent with the expected scaling $t_{\text{initial}} \propto N^{3/2}$ and $t_{\text{evolution}} \propto N \ln N$. The storage requirements also scale as $N \ln N$, governed by the number of nonzero matrix elements in the LU decomposition.

We also show in the same plot the run time per time step for the split-operator algorithm. There is no initialization overhead in that case, the full run time is set by the $N \ln N$ cost of the fast Fourier transform.

[11] The function $\mod(x, y) = x - y \lfloor x/y \rfloor$ returns the greatest integer $\leq x/y$.) The mod function is discontinuous at $y = 0$, jumping from $\lfloor x/y \rfloor$ to $\lfloor x/y \rfloor + 1$ the value of $y$. The choice $\mod(x, y, -y)$ is consistent with the expected scaling.
