**Introduction**

The main purpose of this article is to supply a construction of a three-variable family of cycles interpolating the generalized diagonal cycles introduced in [DR14], and to prove a reciprocity law relating this family to the three variable triple-product $p$-adic $L$-function associated to a triple of Hida families by means of Perrin-Riou’s $\Lambda$-adic regulator.

In order to give a flavor of our construction, let us describe in more detail the organization and contents of this article.

After reviewing some background in the first section, in section 2 we construct for every $r \geq 1$ a completely explicit family of cycles in the cube $X^3_r$ of the modular curve $X_r = X_1(Mp^r)$ of $\Gamma_1(Mp^r)$-level structure. This family is parametrized by the space of $SL_2(Z/p^rZ)$-orbits of the set

$$\Sigma_r := \left( (Z/p^rZ \times Z/p^rZ)^3 \cup (Z/p^rZ)^3 \right)$$

of triples of primitive row vectors of length 2 with entries in $Z/p^rZ$, on which $GL_2(Z/p^rZ)$ acts diagonally by right multiplication. Any triple in $\Sigma_r$ gives rise to a twisted diagonal embedding of the modular curve $X(p^r)$ of $\Gamma_1(M) \cup \Gamma(p^r)$-level structure into the three-fold $X^3_r$ and the associated cycle is defined as the image of this map: we refer to (2.4) for the precise recipe.

The parameter space $\Sigma_r/SL_2(Z/p^rZ)$ is closely related to $(Z/p^rZ)^3 \times (Z/p^rZ)^3$ and as shown throughout §2, the associated family of global cohomology classes introduced in Definition 2.9 can be packaged into a global $\Lambda$-adic cohomology class parametrized by three copies of weight space.

Along §3 and §4 we study the higher weight and crystalline specialisations of this family and we eventually prove in Theorem 4.1 that they interpolate the classes introduced in [DR14] as claimed above.

Finally, in §5 we recall Garrett-Hida’s triple product $p$-adic $L$-function associated to a triple of Hida families $(f, g, h)$ and prove in Theorem 5.1 a reciprocity law expressing the latter as the image of our three-variable cohomology classes (as specified in Definition 5.2) under Perrin-Riou’s $\Lambda$-adic regulator.

It is instructive to compare the construction of our family to the approach taken in [DR17], which associated to a triple $(f, g, h)$ consisting of a fixed newform $f$ and a pair $(g, h)$ of Hida families a one-variable family of cohomology classes instead of the two-variable family that one might have felt entitled to a priori. This shortcoming of the earlier approach can be understood by noting that the space of embeddings of $X(p^r)$ into $X_1(M) \times X_r \times X_r$, as above in which the projection to the first factor is fixed is naturally parametrized by the coset space $M_2(Z/p^rZ)/SL_2(Z/p^rZ)$, where $M_2(Z/p^rZ)$ denotes the set of $2 \times 2$ matrices whose rows are not divisible by $p$. The resulting cycles are therefore parametrized by the coset space $GL_2(Z/p^rZ)/SL_2(Z/p^rZ) = (Z/p^rZ)^3$, whose inverse limit with $r$ is the one dimensional $p$-adic space $Z_p$ rather than a two-dimensional one.
As mentioned already in our previous article in this volume, these cycles are of interest in their own right, and shed a useful complementary perspective on the construction of the $\Lambda$-adic cohomology classes for the triple product when compared to [BSVa]. Indeed, their study forms the basis for the ongoing PhD thesis of David Lilienfeldt [Li], and has led to interesting open questions as those that are explored by Castella and Hsieh in [CS20].

1. Background

1.1. Basic notations. Fix an algebraic closure $\overline{Q}$ of $Q$. All the number fields that arise will be viewed as embedded in this algebraic closure. For each such $K$, let $G_K := \text{Gal}(\overline{Q}/K)$ denote its absolute Galois group. Fix an odd prime $p$ and an embedding $Q \hookrightarrow Q_p$; let $\text{ord}_p$ denote the resulting $p$-adic valuation on $Q^\times$, normalized in such a way that $\text{ord}_p(p) = 1$.

For a variety $V$ defined over $K \subset Q$, let $\hat{V}$ denote the base change of $V$ to $Q$. If $\mathcal{F}$ is an étale sheaf on $V$, write $H_{\acute{e}t}(\hat{V}, \mathcal{F})$ for the $i$th étale cohomology group of $\hat{V}$ with values in $\mathcal{F}$, equipped with its continuous action by $G_K$.

Given a prime $p$, let $Q(\mu_{p^\infty}) = \cup_{r \geq 1} Q(\zeta_r)$ be the cyclotomic extension of $Q$ obtained by adjoining to $Q$ a primitive $p^r$-th root of unity $\zeta_r$. Let

$$\varepsilon_{cyc} : G_Q \longrightarrow \text{Gal}(Q(\mu_{p^\infty})/Q) \longrightarrow \mathbb{Z}_p^\times$$

denote the $p$-adic cyclotomic character. It can be factored as $\varepsilon_{cyc} = \omega \langle \varepsilon_{cyc} \rangle$, where

$$\omega : G_Q \longrightarrow \mu_{p-1} \quad (\varepsilon_{cyc}) : G_Q \longrightarrow 1 + p\mathbb{Z}_p$$

are obtained by composing $\varepsilon_{cyc}$ with the projection onto the first and second factors in the canonical decomposition $\mathbb{Z}_p^\times \cong \mu_{p-1} \times (1 + p\mathbb{Z}_p)$. If $\mathcal{M}$ is a $\mathbb{Z}_p[G_Q]$-module and $j$ is an integer, write $\mathcal{M}(j) = \mathcal{M} \otimes \varepsilon_{cyc}^j$ for the $j$-th Tate twist of $\mathcal{M}$.

Let

$$\hat{\Lambda} := \mathbb{Z}_p[(\mathbb{Z}/p^i\mathbb{Z})^\times] , \quad \Lambda := \mathbb{Z}_p[[\mathbb{Z}_p^\times]] := \varprojlim_r \hat{\Lambda}_r$$

denote the group ring and completed group ring attached to the profinite group $\mathbb{Z}_p^\times$. The ring $\hat{\Lambda}$ is equipped with $p-1$ distinct algebra homomorphisms $\omega^i : \hat{\Lambda} \rightarrow \Lambda$ (for $0 \leq i \leq p-2$) to the local ring

$$\Lambda = \mathbb{Z}_p[[1 + p\mathbb{Z}_p]] = \varprojlim \mathbb{Z}_p[1 + p\mathbb{Z}/p^i\mathbb{Z}] \cong \mathbb{Z}_p[[T]] ,$$

where $\omega^i$ sends a group-like element $a \in \mathbb{Z}_p^\times$ to $\omega^i(a)(a) \in \Lambda$. These homomorphisms identify $\hat{\Lambda}$ with the direct sum

$$\hat{\Lambda} \cong \bigoplus_{i=0}^{p-2} \Lambda .$$

The local ring $\Lambda$ is called the one variable Iwasawa algebra. More generally, for any integer $t \geq 1$, let

$$\hat{\Lambda}^{\otimes t} := \hat{\Lambda} \otimes_{\mathbb{Z}_p} \cdots \otimes_{\mathbb{Z}_p} \Lambda , \quad \Lambda^{\otimes t} = \Lambda \otimes_{\mathbb{Z}_p} \cdots \otimes_{\mathbb{Z}_p} \Lambda \cong \mathbb{Z}_p[[T_1, \ldots, T_t]].$$
The latter ring is called the Iwasawa algebra in $t$ variables, and is isomorphic to the power series ring in $t$ variables over $\mathbb{Z}_p$, while
\[
\Lambda^\otimes_t = \bigoplus_{\alpha} \Lambda^\otimes_t,
\]
the sum running over the $(p-1)^t$ distinct $\mathbb{Z}_p^\times$ valued characters of $(\mathbb{Z}/p\mathbb{Z})^{\times t}$.

1.2. Modular forms and Galois representations. Let
\[
\phi = q + \sum_{n \geq 2} a_n(\phi)q^n \in S_k(M, \chi)
\]
be a cuspidal modular form of weight $k \geq 1$, level $M$ and character $\chi : (\mathbb{Z}/M\mathbb{Z})^\times \to \mathbb{C}^\times$, and assume that $\phi$ is an eigenform with respect to all good Hecke operators $T_\ell$, $\ell \nmid M$.

Fix an odd prime number $p$ (that in this section may or may not divide $M$). Let $O_\phi$ denote the valuation ring of the finite extension of $\mathbb{Q}_p$ generated by the Fourier coefficients of $\phi$, and let $T$ denote the Hecke algebra generated over $\mathbb{Z}_p$ by the good Hecke operators $T_\ell$ with $\ell \nmid M$ and by the diamond operators acting on $S_k(M, \chi)$. The eigenform $\phi$ gives rise to an algebra homomorphism
\[
\xi_\phi : T \longrightarrow O_\phi
\]
sending $T_\ell$ to $a_\ell(\phi)$ and the diamond operator $\langle \ell \rangle$ to $\chi(\ell)$.

A fundamental construction of Shimura, Deligne, and Serre-Deligne attaches to $\phi$ an irreducible Galois representation
\[
\varrho_\phi : G_{\mathbb{Q}} \longrightarrow \text{Aut}(V_\phi) \simeq \text{GL}_2(O_\phi)
\]
of rank 2, unramified at all primes $\ell \mid Mp$, and for which
\[
\det(1 - \varrho_\phi(\text{Fr}_\ell)x) = 1 - a_\ell(\phi)x + \chi(\ell)\ell^{k-1}x^2,
\]
where $\text{Fr}_Y$ denotes the arithmetic Frobenius element at $\ell$. This property characterizes the semi-simplification of $\varrho_\phi$ up to isomorphism.

When $k := k_\circ + 2 \geq 2$, the representation $V_\phi$ can be realised in the $p$-adic étale cohomology of an appropriate Kuga-Sato variety. Since this realisation is important for the construction of generalised Kato classes, we now briefly recall its salient features. Let $Y = \mathcal{Y}_1(M)$ and $X = \mathcal{X}_1(M)$ denote the open and closed modular curve representing the fine moduli functor of isomorphism classes of pairs $(A,P)$ formed by a (generalised) elliptic curve $A$ together with a torsion point $P$ on $A$ of exact order $M$. Let
\[
\pi : \mathcal{A}_\circ \longrightarrow Y
\]
denote the universal elliptic curve over $Y$.

The $k_\circ$-th open Kuga-Sato variety over $Y$ is the $k_\circ$-fold fiber product
\[
\mathcal{A}_\circ^{k_\circ} := \mathcal{A}_\circ \times_Y (k_\circ) \times_Y \mathcal{A}_\circ
\]
of $\mathcal{A}_\circ$ over $Y$. The variety $\mathcal{A}_\circ^{k_\circ}$ admits a smooth compactification $\mathcal{A}^{k_\circ}$ which is fibered over $X$ and is called the $k_\circ$-th Kuga-Sato variety over $X$; we refer to Conrad’s appendix in [BDP13] for more details. The geometric points in $\mathcal{A}^{k_\circ}$ that lie above $Y$ are in bijection with isomorphism classes of tuples $[(A,P), P_1, \ldots, P_{k_\circ}]$, where $(A,P)$ is associated to a point of $Y$ as in the previous paragraph and $P_1, \ldots, P_{k_\circ}$ are points on $A$. 
The representation $V_\phi$ is realized (up to a suitable Tate twist) in the middle degree étale cohomology $H^{k+1}_\text{ét}(\bar{A}_k,\mathbb{Z}_p)$. More precisely, let

$$
\mathcal{H}_r := R^1\pi_*\mathbb{Z}/p^r\mathbb{Z}(1), \quad \mathcal{H} := R^1\pi_*\mathbb{Z}_p(1),
$$

and for any $k\geq 0$, define

$$(1.5) \quad \epsilon_k(H^{k+1}_\text{ét}(\bar{A}_k,\mathbb{Z}_p(k))) = H^{k+1}_\text{ét}(\bar{X},\mathcal{H}^k).$$

Define the sheaves $\mathcal{O}_\phi$-module

$$(1.6) \quad V_\phi(M) := H^1_\text{ét}(\bar{X},\mathcal{H}^k(1)) \otimes_{\mathcal{O}_\phi} \mathcal{O}_\phi,$$

and write

$$(1.7) \quad \varpi_\phi : H^1_\text{ét}(\bar{X},\mathcal{H}^k(1)) \longrightarrow V_\phi(M)$$

for the canonical projection of $\mathbb{T}[G_{\mathbb{Q}}]$-modules arising from (1.6). Deligne’s results and the theory of newforms show that the module $V_\phi(M)$ is the direct sum of several copies of a locally free module $V_\phi$ of rank 2 over $\mathcal{O}_\phi$ that satisfies (1.1).

Let $\alpha_\phi$ and $\beta_\phi$ the two roots of the $p$-th Hecke polynomial $T^2 - a_\phi(T)T + \chi(p)p^{k-1}$, ordered in such a way that $\text{ord}_p(\alpha_\phi) \leq \text{ord}_p(\beta_\phi)$. (If $\alpha_\phi$ and $\beta_\phi$ have the same $p$-adic valuation, simply fix an arbitrary ordering of the two roots.) We set $\chi(p) = 0$ whenever $p$ divides the primitive level of $\phi$ and thus $\alpha_\phi = a_\phi(\phi)$ and $\beta_\phi = 0$ in this case. The eigenform $\phi$ is said to be ordinary at $p$ when $\text{ord}_p(\alpha_\phi) = 0$. In that case, there is an exact sequence of $G_{\mathbb{Q}_p}$-modules

$$(1.8) \quad 0 \rightarrow V^{+}_\phi \longrightarrow V_\phi \longrightarrow V^{-}_\phi \longrightarrow 0, \quad V^{+}_\phi \simeq \mathcal{O}_\phi(\varepsilon_{\text{cyc}}^{-1} \chi_{\psi_\phi}^{-1}), \quad V^{-}_\phi \simeq \mathcal{O}_\phi(\psi_\phi),$$

where $\psi_\phi$ is the unramified character of $G_{\mathbb{Q}_p}$ sending $\text{Fr}_p$ to $\alpha_\phi$.

1.3. Hida families and $\Lambda$-adic Galois representations. Fix a prime $p \geq 3$. The formal spectrum

$$\mathcal{W} := \text{Spf}(\Lambda)$$

of the Iwasawa algebra $\Lambda = \mathbb{Z}_p[[1+p\mathbb{Z}_p]]$ is called the weight space attached to $\Lambda$. The $A$-valued points of $\mathcal{W}$ over a $p$-adic ring $A$ are given by

$$\mathcal{W}(A) = \text{Hom}_{\text{alg}}(\Lambda, A) = \text{Hom}_{\text{grp}}(1 + p\mathbb{Z}_p, A^\times),$$

where the Hom’s in this definition denote continuous homomorphisms of $p$-adic rings and profinite groups respectively. Weight space is equipped with a distinguished collection of arithmetic points $\nu_{k,\varepsilon}$, indexed by integers $k\geq 0$ and Dirichlet characters $\varepsilon : (1+p\mathbb{Z}/p^{r}\mathbb{Z}) \rightarrow \mathbb{Q}_p(\zeta_{p-1})^\times$ of $p$-power conductor. The point $\nu_{k,\varepsilon} \in \mathcal{W}(\mathbb{Z}_p[\zeta_r])$ is defined by

$$\nu_{k,\varepsilon}(n) = \varepsilon(n)n^k,$$
and the notational shorthand $\nu_{k_\epsilon} := \nu_{k_\epsilon, 1}$ is adopted throughout. More generally, if $\Lambda$ is any finite flat $\Lambda$-algebra, a point $x \in \mathcal{W} := \text{Spf}(\Lambda)$ is said to be arithmetic if its restriction to $\Lambda$ agrees with $\nu_{k_\epsilon, \epsilon}$ for some $k_\epsilon$ and $\epsilon$. The integer $k = k_\epsilon + 2$ is called the weight of $x$ and denoted $\text{wt}(x)$.

Let

$$
\zeta_{\text{cyc}} : G_{\mathbb{Q}} \rightarrow \Lambda^\times
$$

denote the $\Lambda$-adic cyclotomic character which sends a Galois element $\sigma$ to the group-like element $[[\zeta_{\text{cyc}}(\sigma)]]$. This character interpolates the powers of the cyclotomic character, in the sense that

$$
\nu_{k_\epsilon, \epsilon} \circ \zeta_{\text{cyc}} = \epsilon \cdot (\zeta_{\text{cyc}})^{k_\epsilon} = \epsilon \cdot \zeta_{\text{cyc}}^k \cdot \omega^{-k_\epsilon}.
$$

Let $M \geq 1$ be an integer not divisible by $p$.

**Definition 1.1.** A Hida family of tame level $M$ and tame character $\chi : (\mathbb{Z}/M\mathbb{Z})^\times \rightarrow \overline{\mathbb{Q}}_p^\times$ is a formal $q$-expansion

$$
\phi = \sum_{n \geq 1} a_n(\phi)q^n \in \Lambda_\phi[[q]]
$$

with coefficients in a finite flat $\Lambda$-algebra $\Lambda_\phi$, such that for any arithmetic point $x \in \mathcal{W}_\phi := \text{Spf}(\Lambda_\phi)$ above $\nu_{k_\epsilon, \epsilon}$, where $k_\epsilon \geq 0$ and $\epsilon$ is a character of conductor $p^r$, the series

$$
\phi_x := \sum_{n \geq 1} x(a_n(\phi))q^n \in \overline{\mathbb{Q}}_p[[q]]
$$

is the $q$-expansion of a classical $p$-ordinary eigenform in the space $S_k(Mp^r, \chi \omega^{-k_\epsilon})$ of cusp forms of weight $k = k_\epsilon + 2$, level $Mp^r$ and nebentype $\chi \omega^{-k_\epsilon}$.

By enlarging $\Lambda_\phi$ if necessary, we shall assume throughout that $\Lambda_\phi$ contains the $M$-th roots of unity.

**Definition 1.2.** Let $x \in \mathcal{W}_\phi$ be an arithmetic point lying above the point $\nu_{k_\epsilon, \epsilon}$ of weight space. The point $x$ is said to be

- tame if the character $\epsilon$ is tamely ramified, i.e., factors through $(\mathbb{Z}/p\mathbb{Z})^\times$.
- crystalline if $\epsilon \omega^{-k_\epsilon} = 1$, i.e., if the weight $k$ specialisation of $\phi$ at $x$ has trival nebentypus character at $p$.

We let $\mathcal{W}_\phi^c$ denote the set of crystalline arithmetic points of $\mathcal{W}_\phi$.

Note that a crystalline point is necessarily tame but of course there are tame points that are not crystalline. The justification for this terminology is that the Galois representation $V_{\phi_0}$ is crystalline at $p$ when $x$ is crystalline.

If $x$ is a crystalline point, then the classical form $\phi_x$ is always old at $p$ if $k > 2$. In that case there exists an eigenform $\phi_0^c$ of level $M$ such that $\phi_x$ is the ordinary $p$-stabilization of $\phi_0^c$. If the weight is $k = 1$ or $2$, $\phi_x$ may be either old or new at $p$; if it is new at $p$ then we set $\phi_0^c = \phi_x$ in order to have uniform notations.

We say $\phi$ is residually irreducible if the mod $p$ Galois representation associated to the Deligne representations associated to $\phi_0^c$ for any crystalline classical point is irreducible.

Finally, the Hida family $\phi$ is said to be primitive of tame level $M_\phi \mid M$ if for all but finitely many arithmetic points $x \in \mathcal{W}_\phi$ of weight $k \geq 2$, the modular form $\phi_x$ arises from a newform of level $M_\phi$. 
The following theorem of Hida and Wiles associates a two-dimensional Galois representation to a Hida family $\phi$ (cf. e.g. [MT90, Théorème 7]).

**Theorem 1.1.** Assume $\phi$ is residually irreducible. Then there is a rank two $\Lambda_\phi$-module $V_\phi$ equipped with a Galois action

\[
\varrho_\phi : G_{Q} \longrightarrow \text{Aut}_{\Lambda_\phi}(V_\phi) \simeq \text{GL}_2(\Lambda_\phi),
\]

such that, for all arithmetic points $x : \Lambda_\phi \longrightarrow \overline{Q}_p$,

\[
V_\phi \otimes_{\Lambda_\phi} \overline{Q}_p \simeq V_{\phi_x} \otimes \overline{Q}_p.
\]

Let

\[
\psi_\phi : G_{Q_p} \longrightarrow \Lambda_\phi^\times
\]

denote the unramified character sending a Frobenius element $\text{Fr}_p$ to $a_p(\phi)$. The restriction of $V_\phi$ to $G_{Q_p}$ admits a filtration

\[
0 \rightarrow V_\phi^+ \rightarrow V_\phi \rightarrow V_\phi^- \rightarrow 0 \quad \text{where} \quad V_\phi^+ \simeq \Lambda_\phi(\psi^{-1}_\phi \chi_{\text{cyc}}^{-1} \chi_{\text{cyc}}) \quad \text{and} \quad V_\phi^- \simeq \Lambda_\phi(\psi_\phi).
\]

The explicit construction of the Galois representation $V_\phi$ plays an important role in defining the generalised Kato classes, and we now recall its main features.

For all $0 \leq r < s$, let

\[
X_r := X_1(Mp^r), \quad X_{r,s} := X_1(Mp^r) \times_{X_0(Mp^r)} X_0(Mp^s),
\]

where the fiber product is taken relative to the natural projection maps. In particular,

- the curve $X := X_0 := X_1(M)$ represents the functor of elliptic curves $A$ with $\Gamma_1(M)$-level structure, i.e., with a marked point of order $M$;
- the curve $X_r$ represents the functor classifying pairs $(A,P)$ consisting of a generalized elliptic curve $A$ with $\Gamma_1(M)$-level structure and a point $P$ of order $p^r$ on $A$;
- the curve $X_{0,s} = X_1(M) \times_{X_0(M)} X_0(Mp^s)$ classifies pairs $(A,C)$ consisting of a generalized elliptic curve $A$ with $\Gamma_1(M)$ structure and a cyclic subgroup scheme $C$ of order $p^s$ on $A$;
- the curve $X_{r,s}$ classifies pairs $(A,P,C)$ consisting of a generalized elliptic curve $A$ with $\Gamma_1(M)$ structure, a point $P$ of order $r$ on $A$ and a cyclic subgroup scheme $C$ of order $p^s$ on $A$ containing $P$.

The curves $X_r$ and $X_{0,r}$ are smooth geometrically connected curves over $Q$. The natural covering map $X_r \longrightarrow X_{0,r}$ is Galois with Galois group $(\mathbb{Z}/p^r\mathbb{Z})^\times$ acting on the left via the diamond operators defined by

\[
\langle a \rangle (A,P) = (A, ap).
\]

Let

\[
\omega_1 : X_{r+1} \longrightarrow X_r
\]

denote the natural projection from level $r + 1$ to level $r$ which corresponds to the map $(A,P) \mapsto (A,ap)$, and to the map $\tau \mapsto \tau$ on upper half planes. Let

\[
\omega_2 : X_{r+1} \longrightarrow X_r
\]
denote the other projection, corresponding to the map \((A, P) \mapsto (A/\langle p^r P \rangle, P + \langle p^r P \rangle)\), which on the upper half plane sends \(\tau\) to \(p\tau\). These maps can be factored as
\[
\begin{align*}
X_{r+1} & \xrightarrow{\mu} X_r, \\
X_{r,r+1} & \xrightarrow{\pi_1} X_r,
\end{align*}
\]
For all \(r \geq 1\), the vertical map \(\mu\) is a cyclic Galois covering of degree \(p\), while the horizontal maps \(\pi_1\) and \(\pi_2\) are non-Galois coverings of degree \(p\). When \(r = 0\), the map \(\mu\) is a cyclic Galois covering of degree \(p - 1\) and \(\pi_2\) are non-Galois coverings of degree \(p + 1\).

The \(\Lambda\)-adic representation \(V_\phi\) shall be realised (up to twists) in quotients of the inverse limit of étale cohomology groups arising from the tower
\[
X^*_\infty : \cdots \xrightarrow{\varpi_1} X_{r+1} \xrightarrow{\varpi_1} X_r \xrightarrow{\varpi_1} \cdots \xrightarrow{\varpi_1} X_1 \xrightarrow{\varpi_1} X_0
\]
of modular curves. Define the inverse limit
\[
H^1_{\text{ét}}(\bar{X}^*_\infty, \mathbb{Z}_p) := \lim_{\varpi_1} H^1_{\text{ét}}(\bar{X}_r, \mathbb{Z}_p)
\]
where the transition maps arise from the pushforward induced by the morphism \(\varpi_1\). This inverse limit is a module over the completed group rings \(\mathbb{Z}_p[[\mathbb{Z}_p^\times]]\) arising from the action of the diamond operators, and is endowed with a plethora of extra structures that we now describe.

**Hecke operators.** The transition maps in (1.16) are compatible with the action of the Hecke operators \(T_n\) for all \(n\) that are not divisible by \(p\). Of crucial importance for us in this article is Atkin’s operator \(U^*_p\), which operates on \(H^1_{\text{ét}}(\bar{X}_r, \mathbb{Z}_p)\) via the composition
\[
U^*_p := \pi_1^* \pi_2^*
\]
arising from the maps in (1.15).

The operator \(U^*_p\) is compatible with the transition maps defining \(H^1_{\text{ét}}(\bar{X}^*_\infty, \mathbb{Z}_p)\).

**Inverse systems of étale sheaves.** The cohomology group \(H^1_{\text{ét}}(\bar{X}^*_\infty, \mathbb{Z}_p)\) can be identified with the first cohomology group of the base curve \(X_1\) with values in a certain inverse systems of étale sheaves.

For each \(r \geq 1\), let
\[
\mathcal{L}^*_r := \varpi_1^{r-1} \mathbb{Z}_p
\]
be the pushforward of the constant sheaf on \(X_r\) via the map
\[
\varpi_1^{r-1} : X_r \longrightarrow X_1
\]
The stalk of \(\mathcal{L}^*_r\) at a geometric point \(x = (A, P)\) on \(X_1\) is given by
\[
\mathcal{L}^*_r, x = \mathbb{Z}_p[A[p^r]/(P)],
\]
where
\[
A[p^r]/(P) := \{Q \in A[p^r] \text{ such that } p^r Q = P\}.
\]
The multiplication by \(p\) map on the fibers gives rise to natural homomorphisms of sheaves
\[
[p] : \mathcal{L}^*_r \longrightarrow \mathcal{L}^*_r.
\]
and Shapiro’s lemma gives canonical identifications
\[ H^1_{\text{ét}}(\overline{X}_r, \mathbb{Z}_p) = H^1_{\text{ét}}(\overline{X}_1, L^r), \]
for which the following diagram commutes:
\[ \begin{array}{c}
H^1_{\text{ét}}(\overline{X}_{r+1}, \mathbb{Z}_p) \xrightarrow{\varphi_{r+1}} H^1_{\text{ét}}(\overline{X}_r, \mathbb{Z}_p) \\
\downarrow \quad \downarrow \quad \downarrow \\
H^1_{\text{ét}}(\overline{X}_1, L^r) \xrightarrow{[p]} H^1_{\text{ét}}(\overline{X}_1, L^r).
\end{array} \]

Let \( L^r_{\infty} := \lim_{\leftarrow r} L^r \) denote the inverse system of étale sheaves relative to the maps \([p]\) arising in (1.18). By passing to the limit, we obtain an identification
(1.19) \[ H^1_{\text{ét}}(\overline{X}^\infty, \mathbb{Z}_p) = \lim_{r \geq 1} H^1_{\text{ét}}(\overline{X}_1, L^r) = H^1_{\text{ét}}(\overline{X}_1, L^\infty). \]

**Weight k specialisation maps.** Recall the \( p \)-adic étale sheaves \( \mathcal{H}^k \) introduced in (1.4), whose cohomology gave rise to the Deligne representations attached to modular forms of weight \( k = k_0 + 2 \) via (1.6). The natural \( k_0 \)-th power symmetrisation function
\[ A^r : \mathcal{H}^k_r \to \mathcal{H}^k, \quad Q \mapsto Q^k, \]
restricted to \( A^r(P) \) and extended to \( L^r \) by \( \mathbb{Z}_p \)-linearity, induces morphisms
(1.20) \[ sp^*_r : L^r \to \mathcal{H}^k_r \]
of sheaves over \( X_1 \) (which are thus compatible with the action of \( G_Q \) on the fibers). These specialisation morphisms are compatible with the transition maps \([p]\) in the sense that the diagram
\[ \begin{array}{c}
L^r_{r+1} \xrightarrow{[p]} L^r_r \\
\downarrow sp^*_r, r+1 \quad \quad \quad \downarrow sp^*_r, r \\
H^k_{r+1} \to H^k_r
\end{array} \]
commutes, where the bottom horizontal arrow denotes the natural reduction map. The maps \( sp^*_r \) can thus be pieced together into morphisms
(1.21) \[ sp^*_k : L^\infty \to \mathcal{H}^k. \]
The induced morphism
(1.22) \[ sp^*_k : H^1_{\text{ét}}(\overline{X}^\infty, \mathbb{Z}_p) \to H^1_{\text{ét}}(\overline{X}_1, \mathcal{H}^k), \]
arising from those on \( H^1_{\text{ét}}(\overline{X}_1, L^\infty) \) via (1.19) will be denoted by the same symbol by abuse of notation, and is referred to as the **weight k = k_0 + 2 specialisation map**. The existence of such maps having finite cokernel reveals that the \( \Lambda \)-adic Galois representation \( H^1_{\text{ét}}(\overline{X}^\infty, \mathbb{Z}_p) \) is rich enough to capture the Deligne representations attached to modular forms on \( X_1 \) of arbitrary weight \( k \geq 2 \).

For each \( a \in 1 + p\mathbb{Z}_p \), the diamond operator \( \langle a \rangle \) acts trivially on \( X_1 \) and as multiplication by \( a^k_0 \) on the stalks of the sheaves \( \mathcal{H}^k_r \). It follows that the
weight $k$ specialisation map $\text{sp}^*_k$ factors through the quotient $H^1_{\text{ét}}(X^*_\infty, \mathbb{Z}_p) \otimes_{\Lambda, \nu_k} \mathbb{Z}_p$, i.e., one obtains a map

$$\text{sp}^*_k : H^1_{\text{ét}}(X^*_\infty, \mathbb{Z}_p) \otimes_{\Lambda, \nu_k} \mathbb{Z}_p \rightarrow H^1_{\text{ét}}(X_1, \mathcal{H}^k).$$

**Remark 1.3.** The inverse limit $\mathcal{C}_\infty$ of the sheaves $\mathcal{C}_\nu^*$ on $X_1$ has been systematically studied by G. Kings in [K15, §2.3-2.4], and is referred to as a sheaf of Iwasawa modules. Jannsen introduced in [J88] the étale cohomology groups of such inverse systems of sheaves, and proved the existence of a Hochschild-Serre spectral sequence, Gysin excision exact sequences and cycle map in this context.

**Ordinary projections.** Let

$$(1.23) \quad e^* := \lim_{n \to \infty} U^*n!$$

denote Hida’s (anti-)ordinary projector. Since $U_p^*$ commutes with the push-forward maps $\varpi_{1*}$, this idempotent operates on $H^1_{\text{ét}}(X^*_\infty, \mathbb{Z}_p)$. While the structure of the $\Lambda$-module $H^1_{\text{ét}}(X^*_\infty, \mathbb{Z}_p)$ seems rather complicated, a dramatic simplification occurs after passing to the quotient $e^*H^1_{\text{ét}}(X^*_\infty, \mathbb{Z}_p)$, as the following classical theorem of Hida shows.

**Theorem 1.2.** [H86, Corollaries 3.3 and 3.7] The Galois representation $e^*H^1_{\text{ét}}(X^*_\infty, \mathbb{Z}_p(1))$ is a free $\Lambda$-module. For each $\nu_k \in \mathcal{W}$ with $k_\ell \geq 0$, the weight $k = k_\ell + 2$ specialisation map induces maps with bounded cokernel (independent of $k$)

$$\text{sp}^*_k : e^*H^1_{\text{ét}}(X^*_\infty, \mathbb{Z}_p(1)) \otimes_{\Lambda, \nu_k} \mathbb{Z}_p \rightarrow e^*H^1_{\text{ét}}(X_1, \mathcal{H}^{k_\ell}(1)).$$

**Galois representations attached to Hida families.** The Galois representation $\mathbb{V}_\phi$ of Theorem 1.1 associated by Hida and Wiles to a Hida family $\phi$ of tame level $M$ and character $\chi$ can be realised as a quotient of the $\Lambda$-module $e^*H^1_{\text{ét}}(X^*_\infty, \mathbb{Z}_p(1))$. More precisely, let

$$\xi_\phi : T_\Lambda \rightarrow \Lambda_\phi$$

be the $\Lambda$-algebra homomorphism from the $\Lambda$-adic Hecke algebra $T_\Lambda$ to the $\Lambda$-algebra $\Lambda_\phi$ generated by the fourier coefficients of $\phi$ sending $T_t$ to $a_t(\phi)$.

Then we have, much as in (1.7), a quotient map of $\Lambda$-adic Galois representations

$$(1.24) \quad \varpi^*_\phi : e^*H^1_{\text{ét}}(X^*_\infty, \mathbb{Z}_p(1)) \rightarrow e^*H^1_{\text{ét}}(X^*_\infty, \mathbb{Z}_p(1)) \otimes_{T_\Lambda, \xi_\phi} \Lambda_\phi =: \mathbb{V}_\phi(M),$$

for which the following diagram of $T_\Lambda[G_\mathbb{Q}]$-modules is commutative:

$$\begin{array}{ccc}
\begin{array}{c}
e^*H^1_{\text{ét}}(X^*_\infty, \mathbb{Z}_p(1))
\end{array} & \xrightarrow{\varpi^*_\phi} & \mathbb{V}_\phi(M) \\
\text{sp}^*_k & \downarrow & \downarrow x \\
\begin{array}{c}
e^*H^1_{\text{ét}}(X_1, \mathcal{H}^{k_\ell}(1))
\end{array} & \xrightarrow{\varpi^*_x} & \mathbb{V}_{\phi_x}(M_p),
\end{array}$$

for all arithmetic points $x$ of $\mathcal{W}_\phi$ of weight $k = k_\ell + 2$ and trivial character.

As in (1.7), $\mathbb{V}_\phi(M)$ is non-canonically isomorphic to a finite direct sum of copies of a $\Lambda_\phi[G_\mathbb{Q}]$-module $\mathbb{V}_\phi$ of rank 2 over $\Lambda_\phi$, satisfying the properties stated in Theorem 1.1.
One can of course work alternatively with the ordinary projection \( e := \lim_{n \to \infty} U_p^n \) rather than the anti-ordinary one, in which case one similarly constructs a quotient map of \( \Lambda \)-adic Galois representations

(1.26) \[ \varphi : eH^1_{\text{et}}(\bar{X}_\infty, \mathbb{Z}_p(1)) := e \lim_{\varphi} H^1_{\text{et}}(\bar{X}_r, \mathbb{Z}_p(1)) \to \mathcal{V}_\phi(M). \]

### 1.4. Families of Dieudonné modules

Let \( B_{\text{dR}} \) denote Fontaine’s field of de Rham periods, \( B_{\text{dR}}^\circ \) be its ring of integers and \( \log[\zeta_{p^n}] \) denote the uniformizer of \( B_{\text{dR}}^\circ \) associated to a norm-compatible system \( \zeta_{p^n} = \{ \zeta_{p^n} \}_{n \geq 0} \) of \( p^n \)-th roots of unity. (cf. e.g. [BK93, §1]). For any finite-dimensional de Rham Galois representation \( V \) of \( G_{\mathbb{Q}_p} \), with coefficients in a finite extension \( L_{p}/\mathbb{Q}_p \), define the de Rham Dieudonné module

\[ D(V) = (V \otimes B_{\text{dR}})^{G_{\mathbb{Q}_p}}, \]

It is an \( L_{p} \)-vector space of the same dimension as \( V \), equipped with a descending exhaustive filtration

\[ \text{Fil}^j D(V) = (V \otimes \log[\zeta_{p^n}] B_{\text{dR}})^{G_{\mathbb{Q}_p}} \]

by \( L_{p} \)-vector subspaces.

Let \( B_{\text{cris}} \subset B_{\text{dR}} \) denote Fontaine’s ring of crystalline \( p \)-adic periods. If \( V \) is crystalline (which is always the case if it arises as a subquotient of the étale cohomology of an algebraic variety with good reduction at \( p \)), then there is a canonical isomorphism

\[ D(V) \simeq (V \otimes B_{\text{cris}})^{G_{\mathbb{Q}_p}}, \]

which furnishes \( D(V) \) with a linear action of a Frobenius endomorphism \( \Phi \).

In [BK93] Bloch and Kato introduced a collection of subspaces of the local Galois cohomology group \( H^1(Q_p, V) \), denoted respectively

\[ H^1_{c}(Q_p, V) \subseteq H^1_{\text{f}}(Q_p, V) \subseteq H^1_{g}(Q_p, V) \subseteq H^1(Q_p, V), \]

and constructed homomorphisms

(1.27) \[ \log_{BK} : H^1_c(Q_p, V) \to D(V)/(\text{Fil}^0 D(V) + D(V)^{\Phi=1}) \]

and

(1.28) \[ \exp_{BK}^* : H^1(Q_p, V)/H^1_g(Q_p, V) \to \text{Fil}^0 D(V) \]

that are usually referred to as the Bloch-Kato logarithm and dual exponential map.

We illustrate the above Bloch-Kato homomorphisms with a few basic examples that shall be used several times in the remainder of this article.

**Example 1.4.** As shown e.g. in [BK93], [B09, §2.2], for any unramified character \( \psi \) of \( G_{\mathbb{Q}_p} \) and all \( n \in \mathbf{Z} \) we have:

(a) If \( n \geq 2 \), or \( n = 1 \) and \( \psi \neq 1 \), then \( H^1_c(Q_p, L_p(\psi e^n_{\text{cyc}})) = H^1(Q_p, L_p(\psi e^n_{\text{cyc}})) \) is one-dimensional over \( L_p \) and the Bloch-Kato logarithm induces an isomorphism

\[ \log_{BK} : H^1(Q_p, L_p(\psi e^n_{\text{cyc}})) \to D(L_p(\psi e^n_{\text{cyc}})). \]

(b) If \( n < 0 \), or \( n = 0 \) and \( \psi \neq 1 \), then \( H^1_g(Q_p, L_p(\psi e^n_{\text{cyc}})) = 0 \) and \( H^1(Q_p, L_p(\psi e^n_{\text{cyc}})) \) is one-dimensional. The dual exponential gives rise to an isomorphism

\[ \exp_{BK}^* : H^1(Q_p, L_p(\psi e^n_{\text{cyc}})) \to \text{Fil}^0 D(L_p(\psi e^n_{\text{cyc}})) = D(L_p(\psi e^n_{\text{cyc}})). \]
(c) Assume $\psi = 1$. If $n = 0$, then $H^1(Q_p, L_p)$ has dimension 2 over $L_p$, $H^1_\ell(Q_p, L_p) = H^1_s(Q_p, L_p)$ has dimension 1 and $H^1_{s\ell}(Q_p, L_p)$ has dimension 0 over $L_p$. The Bloch-Kato dual exponential map induces an isomorphism
\[ \exp_{BK} : H^1(Q_p, L_p)/H^1_\ell(Q_p, L_p) \xrightarrow{\sim} \text{Fil}^0 D(L_p) = D(L_p) = L_p. \]
Class field theory identifies $H^1(Q_p, L_p)$ with $\text{Hom}_{\text{cont}}(Q_p^\times, Q_p) \otimes L_p$, which is spanned by the homomorphisms $\text{ord}_p$ and $\log_p$.

If $n = 1$, then $H^1(Q_p, L_p(1)) = H^1_s(Q_p, L_p(1))$ is 2-dimensional and $H^1_\ell(Q_p, L_p(1)) = H^1_{s\ell}(Q_p, L_p(1))$ has dimension 1 over $L_p$. As proved e.g. in [B09, Prop. 2.9], Kummer theory identifies the spaces $H^1_\ell(Q_p, L_p(1)) \subset H^1(Q_p, L_p(1))$ with $\mathbb{Z}_p^\times \otimes L_p$ sitting inside $Q_p^\times \otimes L_p$.

Under this identification, the Bloch-Kato logarithm is the usual $p$-adic logarithm on $\mathbb{Z}_p^\times$.

Let $\mathbb{Z}_p^{nr}$ denote the ring of integers of the completion of the maximal unramified extension of $Q_p$. If $V$ is unramified then there is a further canonical isomorphism
\[ (1.29) \quad D(V) \simeq (V \otimes \mathbb{Z}_p^{nr})^G_{Q_p}. \]

Let $\phi$ be an eigenform (with respect to the good Hecke operators) of weight $k = k + 2 \geq 2$, level $M$ and character $\chi$, with Fourier coefficients in a finite extension $L_p$ of $Q_p$. The comparison theorem [F97] of Faltings-Tsuji combined with (1.6) asserts that there is a natural isomorphism
\[ D(V_M) \simeq H^1_\text{dR}(X_1(M), H^{k_{1}}(1))\langle \phi \rangle \]

of Dieudonné modules over $L_p$. Note that $D(V_M)$ is the direct sum of several copies of the two-dimensional Dieudonné module $D(V_\phi)$.

Assume that $p \nmid M$ and $\phi$ is ordinary at $p$. Then $V_M$ is crystalline and $\Phi$ acts on $D(V_M)$ as
\[ \Phi = \chi(p)p^{k_{1}+1}U_{p}^{-1}. \]

In particular the eigenvalues of $\Phi$ on $D(V_\phi(M))$ are $\chi(p)p^{k_{1}+1}\alpha_{\phi}^{-1} = \beta_{\phi}$ and $\chi(p)p^{k_{1}+1}\beta_{\phi}^{-1} = \alpha_{\phi}$, the two roots of the Hecke polynomial of $\phi$ at $p$. For future reference, recall from [DR14, Theorem 1.3] the Euler factors
\[ (1.31) \quad \mathcal{E}_{\phi}(\phi) := 1 - \chi^{-1}(p)\beta_{\phi}^{2}p^{1-k} = 1 - \frac{\beta_{\phi}^{2}}{\alpha_{\phi}^{2}}, \quad \mathcal{E}_{1}(\phi) := 1 - \chi(p)\alpha_{\phi}^{-2}p^{k-2}. \]

Let $\phi^* = \phi \otimes \bar{\chi} \in S_{k}(M, \bar{\chi})$ denote the twist of $\phi$ by the inverse of its nebentype character. Poincaré duality induces a perfect pairing
\[ \langle \cdot, \cdot \rangle : D(V_\phi(M)) \times D(V_{\phi^*}(M)) \rightarrow D(L_p) = L_p. \]

The exact sequence (1.8) induces in this setting an exact sequence of Dieudonné modules
\[ (1.32) \quad 0 \rightarrow D(V_\phi^+(M)) \xrightarrow{i} D(V_\phi(M)) \xrightarrow{\pi} D(V_\phi^-(M)) \rightarrow 0. \]

Since $V_\phi^-(M)$ is unramified, we have $D(V_\phi^-(M)) \simeq (V_\phi^-(M) \otimes \mathbb{Z}_p^{nr})^G_{Q_p}$. This submodule may also be characterized as the eigenspace $D(V_\phi^-(M)) = D(V_\phi(M))^{\phi = \alpha_{\phi}}$ of eigenvalue $\alpha_{\phi}$ for the action of frobenius.
The rule $\tilde{\phi} \mapsto \omega_{\tilde{\phi}}$ that attaches to a modular form its associated differential form gives rise to an isomorphism $S_k(M, \chi)_{L_p}[\phi] \overset{\sim}{\rightarrow} \text{Fil}^0(D(\phi)(M)) \subset D(\phi)(M))$. Moreover, the map $\pi$ of (1.32) induces an isomorphism

\[(1.33) \quad S_k(M, \chi)_{L_p}[\phi] \overset{\sim}{\rightarrow} \text{Fil}^0(D(\phi)(M)) \overset{\text{can}}{\rightarrow} D(\phi^-)(M)).\]

Any element $\omega \in D(\phi^-)(M))$ gives rise to a linear map

\[\omega : D(\phi^-)(M)) \rightarrow L_p, \quad \eta \mapsto \langle \eta, \pi^{-1}(\omega) \rangle.\]

Similarly, any $\eta \in D(\phi^+(M))$ may be identified with a linear functional

\[\eta : D(\phi^+(M)) \rightarrow L_p, \quad \omega \mapsto \langle \pi^{-1}(\omega), \eta \rangle,\]

and given $\tilde{\phi} \in S_k(M, \chi)_{L_p}[\phi]$ we set $\eta_{\tilde{\phi}} : D(\phi^-)(M)) \rightarrow L_p, \quad \varphi \mapsto \eta_{\tilde{\phi}}(\varphi) = \langle \tilde{\phi}, \varphi \rangle_{\phi^+}.$

Let now $\tilde{\Lambda}$ be a finite flat extension of the Iwasawa algebra $\Lambda$ and let $\mathbb{U}$ denote a free $\tilde{\Lambda}$-module of finite rank equipped with an unramified $\tilde{\Lambda}$-linear action of $G_{\mathbb{Q}_p}$. Define the $\Lambda$-adic Dieudonné module

\[\mathbb{D}(\mathbb{U}) := (\mathbb{U} \otimes \mathbb{Z}_p^\infty)^{G_{\mathbb{Q}_p}}.\]

As shown in e.g. [O03, Lemma 3.3], $\mathbb{D}(\mathbb{U})$ is a free module over $\tilde{\Lambda}$ of the same rank as $\mathbb{U}$.

Examples of such $\Lambda$-adic Dieudonné modules arise naturally in the context of families of modular forms thanks to Theorem 1.1. Indeed, let $\phi$ be a Hida family of tame level $M$ and character $\chi$, and let $\phi^*$ denote the $\Lambda$-adic modular form obtained by twisting $\phi$ by $\tilde{\chi}$.

Let $\mathbb{V}_{\phi}$ and $\mathbb{V}_{\phi}(M)$ denote the global $\Lambda$-adic Galois representations described in (1.24). It follows from (1.12) that to the restriction of $\mathbb{V}_{\phi}$ to $G_{\mathbb{Q}_p}$ one might associate two natural unramified $\Lambda[\mathbb{Z}_p^\infty]$-modules of rank one, namely

\[\mathbb{V}_{\phi} \simeq \Lambda[\phi](\psi_{\phi}) \quad \text{and} \quad \mathbb{U}^+_\phi = \mathbb{V}_{\phi}(\chi^{-1} \epsilon_{\text{cyc}} \mathbb{Z}_p^\infty).\]

Define similarly the unramified modules $\mathbb{V}_\phi^-(M)$ and $\mathbb{U}^+_\phi(M)$.

Let

\[(1.34) \quad S^\text{ord}_\Lambda(M, \chi)[\phi] := \left\{ \tilde{\phi} \in S^\text{ord}_\Lambda(M, \chi) \mid \begin{array}{l} T_\ell \tilde{\phi} = a_\ell(\phi) \tilde{\phi}, \quad \forall \ell \nmid Mp, \\
U_p \tilde{\phi} = a_p(\phi) \tilde{\phi} \end{array} \right\},\]

For any crystalline arithmetic point $x \in W^\text{cr}_\phi$ of weight $k$, the specialization of a $\Lambda$-adic test vector $\tilde{\phi} \in S^\text{ord}_\Lambda(M, \chi)[\phi]$ at $x$ is a classical eigenform $\phi_x \in S_k(M, \chi)$ with coefficients in $L_p = x(\Lambda[\phi]) \otimes \mathbb{Q}_p$ and the same eigenvalues as $\phi_x$ for the good Hecke operators.

Likewise, define

\[S^\text{ord}_\Lambda(M, \chi)^\vee[\phi] = \left\{ \eta : S^\text{ord}_\Lambda(M, \chi) \rightarrow \Lambda[\phi] \mid \begin{array}{l} \eta \circ T_\ell^* = a_\ell(\phi) \eta, \quad \forall \ell \nmid Mp, \\
\eta \circ U_p^* = a_p(\phi) \eta \end{array} \right\}.\]

Let $\mathbb{Q}_\phi$ denote the field of fractions of $\Lambda[\phi]$. Associated to any test vector $\tilde{\phi} \in S^\text{ord}_\Lambda(M, \chi)[\phi]$, [DR14, Lemma 2.19] describes a $\mathbb{Q}_\phi$-linear dual test
vector 
\[(1.35) \quad \tilde{\phi}^\vee \in S^\text{ord}_\Lambda(M, \bar{\chi})^\vee[\phi] \otimes \mathbb{Q}_\phi \]
such that for any $\phi \in S^\text{ord}_\Lambda(M, \bar{\chi})$ and any point $x \in \mathcal{W}_f^\circ$, 
\[x(\tilde{\phi}^\vee(\phi)) = \frac{\langle \tilde{\phi}_x, \phi_x \rangle}{\langle \tilde{\phi}_x, \phi^\circ_x \rangle} \]
where $(,)$ denotes the pairing induced by Poincaré duality on the modular curve associated to the congruence subgroup $\Gamma_1(M) \cap \Gamma_0(p)$. This way, the specialization of a $\Lambda$-adic dual test vector $\tilde{\phi}^\vee \in S^\text{ord}_\Lambda(M, \bar{\chi})^\vee[\phi]$ at $x$ gives rise to a linear functional 
\[\eta_{\phi_x} : S_k(Mp, \bar{\chi})[\phi^\circ_x] \longrightarrow L_p.\]

A natural $\mathbb{Q}_F$-basis of $S^\text{ord}_\Lambda(M, \chi)[\phi] \otimes \mathbb{Q}_\phi$ is given by the $\Lambda$-adic modular forms $\phi(q^d)$ as $d$ ranges over the positive divisors of $M/M_\phi$ and it is also obvious that $\{\phi(q^d)^\vee : d | \frac{M}{M_\phi}\}$ provides a $\mathbb{Q}_\phi$-basis of $S^\text{ord}_\Lambda(M, \bar{\chi})^\vee[\phi] \otimes \mathbb{Q}_\phi$.

The following statement shows that the linear maps described above can be made to vary in families.

**Proposition 1.5.** For any $\Lambda$-adic test vector $\tilde{\phi} \in S^\text{ord}_\Lambda(M, \chi)[\phi]$ there exist homomorphisms of $\Lambda_\phi$-modules 
\[\omega_{\tilde{\phi}} : D(U^*_\phi^\circ(M)) \longrightarrow \Lambda_\phi, \quad \eta_{\tilde{\phi}} : D(V^*_\phi^\circ(M)) \longrightarrow \mathbb{Q}_\phi,\]
whose specialization at a classical point $x \in \mathcal{W}_f^\circ$ such that $\phi_x$ is the ordinary stabilization of an eigenform $\phi^\circ_x$ of level $M$ are, respectively 
\begin{enumerate}
  \item $x \circ \omega_{\tilde{\phi}} = \mathcal{E}_0(\phi^\circ_x) \cdot e^{\varpi_1^*(\omega_{\phi^\circ})}$ as functionals on $D(U^*_\phi^\circ(Mp))$.
  \item $x \circ \eta_{\tilde{\phi}} = \frac{1}{\varepsilon_1(\phi^\circ_x)} \cdot e^{\varpi_1^*(\eta_{\phi^\circ})}$ as functionals on $D(V^*_\phi^\circ(Mp))$.
\end{enumerate}

**Démonstration.** This is essentially a reformulation of [KLZ17, Propositions 10.1.1 and 10.1.2], which in turn builds on [0000]. Namely, the first claim in Prop.10.1.2 of loc.cit. asserts that $\omega_{\tilde{\phi}}$ exists such that at any $x \in \mathcal{W}_f^\circ$ as above, $x \circ \omega_{\tilde{\phi}} = \omega_{\phi_x} = \text{Pr}^{\alpha_\phi}(\omega_{\phi^\circ_x})$ where $\text{Pr}^{\alpha_\phi}$ is the map defined in [KLZ17, 10.1.3] sending $\phi^\circ_x$ to its ordinary $p$-stabilization $\tilde{\phi}_x$. Note that $\varpi_1^*(\phi^\circ_x) = \frac{\alpha_{\phi^\circ_x} - \beta_{\phi^\circ_x}}{\alpha_{\phi^\circ_x} - \beta_{\phi^\circ_x}}$, where $\tilde{\phi}_x$ denotes the non-ordinary specialization of $\phi^\circ_x$.

Since $\omega_{\phi^\circ_x} = 0$ and $\mathcal{E}_0(\phi^\circ_x) = \frac{\alpha_{\phi^\circ_x} - \beta_{\phi^\circ_x}}{\alpha_{\phi^\circ_x}}$ the claim follows.

The second part of [KLZ17, Proposition 10.1.2] asserts that there exists a $\Lambda$-adic functional $\tilde{\eta}_{\phi}$ such that for all $x$ as above:

\[x \circ \tilde{\eta}_{\phi} = \frac{\text{Pr}^{\alpha_\phi} \eta_{\phi^\circ_x}}{\Lambda(\phi^\circ_x) \mathcal{E}_0(\phi^\circ_x) \mathcal{E}_1(\phi^\circ_x)}\]
as $L_p$-linear functionals on $D(V^*_\phi^\circ(Mp))$. Here $\Lambda(\phi^\circ_x) \in \mathbb{Q}^\times$ denotes the pseudo-eigenvalue of $\phi^\circ_x$, which we recall is the scalar given by 
\[(1.36) \quad W_M(\phi^\circ_x) = \Lambda(\phi^\circ_x) \cdot \phi^\circ_x, \]
where $W_M : S_k(M, \chi) \rightarrow S_k(M, \chi^{-1})$ stands for the Atkin-Lehner operator. Since we are assuming that $\Lambda_\phi$ contains the $M$-th roots of unity (cf. the
remark right after Definition 1.1), Prop. 10.1.1 of loc. cit. shows that there exists an element $\lambda(\phi) \in \Lambda_\phi$ interpolating the pseudo-eigenvalues of the classical $p$-stabilized specializations of $\phi$. The claim follows by taking $\eta_\phi = \lambda(\phi)\tilde{\eta}_\phi$. The same argument as above yields that for all $x$ as above, $x \circ \eta_\phi = E_0(\phi \circ x) e^{\eta_\phi \tilde{\eta}_\phi} E_0(\phi \circ x)$, which amounts to the statement of the proposition. □

2. Generalised Kato classes

2.1. A compatible collection of cycles. This section defines a collection of codimension two cycles in $X_1(Mp^r)^3$ indexed by elements of $(\mathbb{Z}/p^r\mathbb{Z})^3$ and records some of their properties.

We retain the notations that were in force in Section 1.3 regarding the meanings of the curves $X = X_1(M)$, $X_r = X_1(Mp^r)$ and $X_{r,s}$. In addition, let $Y(p^r) := Y \times_{X_1} Y(p^r)$, $X(p^r) := X \times_{X_1} X(p^r)$ denote the (affine and projective, respectively) modular curve over $\mathbb{Q}((\zeta))$ with full level $p^r$ structure. The curve $Y(p^r)$ classifies triples $(A,P,Q)$ in which $A$ is an elliptic curve with $\Gamma_1(M)$ level structure and $(P,Q)$ is a basis for $A[p^r]$ satisfying $\langle P,Q \rangle = \zeta_r$, where $\langle , \rangle$ denotes the Weil pairing and $\zeta_r$ is a fixed primitive $p^r$-th root of unity. The curve $X(p^r)$ is geometrically connected but does not descend to a curve over $\mathbb{Q}$, as can be seen by noting that the description of its moduli problem depends on the choice of $\zeta_r$. The covering $X(p^r)/X$ is Galois with Galois group $SL_2(\mathbb{Z}/p^r\mathbb{Z})$, acting on the left by the rule

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \mapsto (A,aP+bQ,cP+dQ).$$

Consider the natural projection map

$$\varpi^r : X_1 \times X_1 \times X_1 : X_1^3 \rightarrow X^3$$

induced on triple products by the map $\varpi^r$ of (1.14). Write $\Delta \subset X^3$ for the usual diagonal cycle, namely the image of $X$ under the diagonal embedding $x \mapsto (x,x,x)$. Let $\Delta_r$ be the fiber product $\Delta \times_{X^3} X_r^3$ via the natural inclusion and the map of (2.2), which fits into the cartesian diagram

$$\Delta_r \rightarrow X_r^3 \rightarrow X^3.$$

An element of a $\mathbb{Z}_{p^r}$-module $\Omega$ is said to be primitive if it does not belong to $p\Omega$, and the set of such primitive elements is denoted $\Omega'$. Let

$$\Sigma_r := ((\mathbb{Z}/p^r\mathbb{Z} \times \mathbb{Z}/p^r\mathbb{Z}))^3 \subset ((\mathbb{Z}/p^r\mathbb{Z}))^3$$

be the set of triples of primitive row vectors of length 2 with entries in $\mathbb{Z}/p^r\mathbb{Z}$, equipped with the action of $GL_2(\mathbb{Z}/p^r\mathbb{Z})$ acting diagonally by right multiplication.
Lemma 2.1. The geometrically irreducible components of $\Delta_r$ are defined over $\mathbb{Q}(\zeta_r)$ and are in canonical bijection with the set of left orbits
$$\Sigma_r/\text{SL}_2(\mathbb{Z}/p^r\mathbb{Z}).$$

Démonstration. Each triple
$$(v_1, v_2, v_3) = ((x_1, y_1), (x_2, y_2), (x_3, y_3)) \in \Sigma_r$$
determines a morphism
$$\varphi_{(v_1,v_2,v_3)} : \mathbb{X}(p^r) \to \Delta_r \subset X^3_r$$
of curves over $\mathbb{Q}(\zeta_r)$, defined in terms of the moduli descriptions on $\mathbb{Y}(p^r)$ by
$$(A, P, Q) \mapsto (A, x_1 P + y_1 Q), (A, x_2 P + y_2 Q), (A, x_3 P + y_3 Q).$$

It is easy to see that if two elements $(v_1, v_2, v_3)$ and $(v'_1, v'_2, v'_3) \in \Sigma_r$ satisfy
$$(v'_1, v'_2, v'_3) = (v_1, v_2, v_3)\gamma, \quad \text{with } \gamma \in \text{SL}_2(\mathbb{Z}/p^r\mathbb{Z}),$$
then
$$\varphi_{(v'_1,v'_2,v'_3)} = \varphi_{(v_1,v_2,v_3)} \circ \gamma,$$
where $\gamma$ is being viewed as an automorphism of $\mathbb{X}(p^r)$ as in (2.1). It follows that the geometrically irreducible cycle
$$\Delta_r(v_1, v_2, v_3) := \varphi_{(v_1,v_2,v_3)}^*(\mathbb{X}(p^r))$$
depends only on the $\text{SL}_2(\mathbb{Z}/p^r\mathbb{Z})$-orbit of $(v_1, v_2, v_3)$.

Since $\text{SL}_2(\mathbb{Z}/p^r\mathbb{Z})$ acts transitively on $(\mathbb{Z}/p^r\mathbb{Z} \times \mathbb{Z}/p^r\mathbb{Z})^3$, one further checks that the collection of cycles $\Delta_r(v_1, v_2, v_3)$ for $(v_1, v_2, v_3) \in \Sigma_r/\text{SL}_2(\mathbb{Z}/p^r\mathbb{Z})$ do not overlap on $\mathbb{Y}_3^r$ and cover $\Delta_r$. Hence the irreducible components of $\Delta_r$ are precisely $\Delta_r(v_1, v_2, v_3)$ for $(v_1, v_2, v_3) \in \Sigma_r/\text{SL}_2(\mathbb{Z}/p^r\mathbb{Z})$.

The quotient $\Sigma_r/\text{SL}_2(\mathbb{Z}/p^r\mathbb{Z})$ is equipped with a natural determinant map
$$D : \Sigma_r/\text{SL}_2(\mathbb{Z}/p^r\mathbb{Z}) \to (\mathbb{Z}/p^r\mathbb{Z})^3$$
defined by
$$D ((x_1 y_1), (x_2 y_2), (x_3 y_3)) := \left( \begin{array}{ccc} x_2 & y_2 & x_3 \\ x_3 & y_3 & x_1 \\ x_1 & y_1 & x_2 \end{array} \right).$$

For each $[d_1, d_2, d_3] \in (\mathbb{Z}/p^r\mathbb{Z})^3$, we can then write
$$\Sigma_r[d_1, d_2, d_3] := \{(v_1, v_2, v_3) \in \Sigma_r \text{ with } D(v_1, v_2, v_3) = (d_1, d_2, d_3)\}.$$
The group $\text{SL}_2(\mathbb{Z}/p^r\mathbb{Z})$ operates simply transitively on $\Sigma_r[d_1, d_2, d_3]$ if (and only if)
$$(2.3) \quad [d_1, d_2, d_3] \in \text{I}_r := (\mathbb{Z}/p^r\mathbb{Z})^3.$$

In particular, if $(v_1, v_2, v_3)$ belongs to $\Sigma_r[d_1, d_2, d_3]$, then the cycle $\Delta_r(v_1, v_2, v_3)$ depends only on $[d_1, d_2, d_3] \in \text{I}_r$ and will henceforth be denoted
$$(2.4) \quad \Delta_r[d_1, d_2, d_3] \in \text{CH}_2(X^3_r).$$

A somewhat more intrinsic definition of $\Delta_r[d_1, d_2, d_3]$ as a curve embedded in $X^3_r$ is that it corresponds to the schematic closure of the locus of points $((A, P_1), (A, P_2), (A, P_3))$ satisfying
$$(2.5) \quad \langle P_2, P_3 \rangle = \zeta_r^{d_1}, \quad \langle P_3, P_1 \rangle = \zeta_r^{d_2}, \quad \langle P_1, P_2 \rangle = \zeta_r^{d_3}.$$
This description also makes it apparent that the cycle \( \Delta_r[d_1, d_2, d_3] \) is defined over \( \mathbb{Q}(\zeta_r) \) but not over \( \mathbb{Q} \). Let \( \sigma_m \in \text{Gal} (\mathbb{Q}(\zeta_r)/\mathbb{Q}) \) be the automorphism associated to \( m \in (\mathbb{Z}/p^r \mathbb{Z})^{\times} \), sending \( \zeta_r \) to \( \zeta_r^m \). The threefold \( X^3_r \) is also equipped with an action of the group

\[
\hat{G}_r := ((\mathbb{Z}/p^r \mathbb{Z})^{\times})^3 \{ (a_1, a_2, a_3), \ a_1, a_2, a_3 \in (\mathbb{Z}/p^r \mathbb{Z})^{\times} \}
\]

of diamond operators, where the automorphism associated to a triple \(( (a_1), (a_2), (a_3) \)) has simply been denoted \( (a_1, a_2, a_3) \).

**Lemma 2.2.** For all diamond operators \((a_1, a_2, a_3) \in \hat{G}_r \) and all \([d_1, d_2, d_3]) \in I_r,\)

\[
(a_1, a_2, a_3) \Delta_r[d_1, d_2, d_3] = \Delta_r[a_2a_3 \cdot d_1, a_1a_3 \cdot d_2, a_1a_2 \cdot d_3].
\]

For all \( \sigma_m \in \text{Gal} (\mathbb{Q}(\zeta_r)/\mathbb{Q}), \)

\[
\sigma_m \Delta_r[d_1, d_2, d_3] = \Delta_r[m \cdot d_1, m \cdot d_2, m \cdot d_3].
\]

**Démonstration.** Equation (2.7) follows directly from the identity

\[
D(a_1v_1, a_2v_2, a_3v_3) = [a_2a_3, a_1a_3, a_1a_2]D(v_1, v_2, v_3).
\]

The first equality in (2.8) is most readily seen from the equation (2.5) defining the cycle \( \Delta_r[d_1, d_2, d_3] \), since applying the automorphism \( \sigma_m \in \text{Gal} (\mathbb{Q}(\zeta_r)/\mathbb{Q}) \) has the effect of replacing \( \zeta_r \) by \( \zeta_r^m \). \( \square \)

**Remark 2.3.** Assume \( m \) is a quadratic residue in \((\mathbb{Z}/p^r \mathbb{Z})^{\times} \), which is the case, for instance, when \( \sigma_m \) belongs to \( \text{Gal} (\mathbb{Q}(\zeta_r)/\mathbb{Q}(\zeta)) \). Then it follows from (2.7) and (2.8) that

\[
\sigma_m \Delta_r[d_1, d_2, d_3] = \langle m, m, m \rangle^{1/2} \Delta_r[d_1, d_2, d_3].
\]

Let us now turn to the compatibility properties of the cycles \( \Delta_r[d_1, d_2, d_3] \) as the level \( r \) varies. Recall the modular curve \( X_{r,r+1} \) classifying generalised elliptic curves together with a distinguished cyclic subgroup of order \( p^{r+1} \) and a point of order \( p^r \) in it. The maps \( \mu, \varpi_1, \varpi_2 \) and \( \varpi_2 \) of (1.15) induce similar maps on the triple products:

\[
\begin{align*}
X^3_{r+1} & \xrightarrow{\mu^3} X^3_r, \\
X^3_{r,r+1} & \xrightarrow{\pi_1^3} X^3_r,
\end{align*}
\]

\[
\begin{align*}
X^3_{r+1} & \xrightarrow{\mu^3} X^3_r, \\
X^3_{r,r+1} & \xrightarrow{\pi_2^3} X^3_r.
\end{align*}
\]

A finite morphism \( j : V_1 \to V_2 \) of varieties induces maps

\[
\begin{align*}
j_* : \text{CH}^j(V_1) & \to \text{CH}^j(V_2), \\
j^* : \text{CH}^j(V_2) & \to \text{CH}^j(V_1)
\end{align*}
\]

between Chow groups, and \( j_*j^* \) agrees with the multiplication by \( \deg(j) \) on \( \text{CH}^j(V_2) \). If \( j \) is a Galois cover with Galois group \( G, \)

\[
\sum_{\sigma \in G} \sigma \Delta.
\]

By abuse of notation we will denote the associated maps on cycles (rather than just on cycle classes) by the same symbols.
Lemma 2.4. For all \( r \geq 1 \) and all \([d_1', d_2', d_3'] \in I_{r+1}\) whose image in \( I_r \) is \([d_1, d_2, d_3]\),
\[
(\pi^3_1)_* \Delta_{r+1}[d_1', d_2', d_3'] = p^3 \Delta_r[d_1, d_2, d_3],
\]
\[
(\pi^3_2)_* \Delta_{r+1}[d_1', d_2', d_3'] = (U_p)^{\otimes 3} \Delta_r[d_1, d_2, d_3].
\]
The cycles \( \Delta_r[d_1, d_2, d_3] \) also satisfy the distribution relations
\[
\sum_{[d_1', d_2', d_3']} \Delta_{r+1}[d_1', d_2', d_3'] = (\pi^3_1)^* \Delta_r[d_1, d_2, d_3],
\]
where the sum is taken over all triples \([d_1', d_2', d_3'] \in I_{r+1} \) which map to \([d_1, d_2, d_3] \) in \( I_r \).

Démonstration. A direct verification based on the definitions shows that the morphisms \( \mu^3 \) and \( \pi^3_1 \) of (2.10) induce morphisms
\[
\Delta_{r+1}[d_1', d_2', d_3'] \xrightarrow{\mu^3} \Delta_{r+1}[d_1', d_2', d_3'] \xrightarrow{\pi^3_1} \Delta_r[d_1, d_2, d_3],
\]
of degrees 1 and \( p^3 \) respectively. Hence the restriction of \( \omega^3 \) to \( \Delta_{r+1}[d_1', d_2', d_3'] \) induces a map of degree \( p^3 \) from \( \Delta_{r+1}[d_1', d_2', d_3'] \) to \( \Delta_r[d_1, d_2, d_3] \), which implies the first assertion. It also follows from this that
\[
(\pi^3_2)_* \Delta_{r+1}[d_1', d_2', d_3'] = (U_p)^{\otimes 3} \Delta_r[d_1, d_2, d_3].
\]
Applying \( (\pi^3_2)_* \) to this identity implies that
\[
(\pi^3_1)_* \Delta_{r+1}[d_1', d_2', d_3'] = (\pi^3_1)^* \Delta_r[d_1, d_2, d_3].
\]
The second compatibility relation follows. To prove the distribution relation, observe that the sum that occurs in it is taken over \( p^3 \) translates of a fixed \( \Delta_{r+1}[d_1', d_2', d_3'] \) for the action of the Galois group of \( X_{r+1} \) over \( X_{r,r+1} \), and hence, by (2.11), that
\[
\sum_{[d_1', d_2', d_3']} \Delta_{r+1}[d_1', d_2', d_3'] = (\mu^*)^3 (\pi^3_1)^* \Delta_{r+1}[d_1', d_2', d_3'].
\]
The result then follows from (2.12). \( \square \)

2.2. Galois cohomology classes. The goal of this section is to parlay the cycles \( \Delta_r[d_1, d_2, d_3] \) into Galois cohomology classes with values in \( H^3_{\acute{e}t}(\bar{X}_r, \mathbb{Z}_p)^{\otimes 3} \) (2), essentially by considering their images under the \( p \)-adic étale Abel-Jacobi map:
\[
(2.13) \quad \AJ_{\acute{e}t} : \CH^2(X^3_r)_0 \longrightarrow H^1(Q, H^3_{\acute{e}t}(\bar{X}_r, \mathbb{Z}_p(2))),
\]
where
\[
\CH^2(X^3_r)_0 := \ker \left( \CH^2(X^3_r) \longrightarrow H^4_{\acute{e}t}(\bar{X}_r, \mathbb{Z}_p(2)) \right)
\]
denotes the kernel of the étale cycle class map, i.e., the group of null-homologous algebraic cycles defined over \( Q \). There are two issues that need to be dealt with. Firstly, the cycles \( \Delta_r[d_1, d_2, d_3] \) need not be null-homologous and have to be suitably modified so that they lie in the domain of the Abel Jacobi map. Secondly, these cycles are defined over \( Q(\zeta_r) \) and not over \( Q \), and it is desirable to descend the field of definition of the associated extension classes.
To deal with the first issue, let \( q \) be any prime not dividing \( M_p \), and let \( T_q \) denote the Hecke operator attached to this prime. It can be used to construct an algebraic correspondence on \( X^3_r \) by setting
\[
\theta_q := (T_q - (q + 1))^{\otimes 3}.
\]

**Lemma 2.5.** The element \( \theta_q \) annihilates the target \( H^3_{\et}(X^3_r, \mathbb{Z}_p) \) of the étale cycle class map on \( \text{CH}^2(X_r^3) \).

**Démonstration.** The correspondence \( T_q \) acts as multiplication by \((q + 1) \) on \( H^2_{\et}(X_r, \mathbb{Z}_p) \) and \( \theta_q \) therefore annihilates all the terms in the Künneth decomposition of \( H^3_{\et}(X_r, \mathbb{Z}_p) \).

The modified diagonal cycles in \( \text{CH}^2(X_r^3) \) are defined by the rule
\[
\Delta^\circ_r[d_1, d_2, d_3] := \theta_q \Delta_r[d_1, d_2, d_3].
\]

Lemma 2.5 shows that they are null-homologous and defined over \( \mathbb{Q}(\zeta_r) \). Define
\[
\kappa_r[d_1, d_2, d_3] := \text{AJ}_{\et}(\Delta^\circ_r[d_1, d_2, d_3]) \in H^1(\mathbb{Q}(\zeta_r), H^3_{\et}(X_r, \mathbb{Z}_p)^{\otimes 3}(2)).
\]

To deal with the circumstance that the cycles \( \Delta^\circ_r[d_1, d_2, d_3] \) are only defined over \( \mathbb{Q}(\zeta_r) \), and hence that the associated cohomology classes \( \kappa_r[d_1, d_2, d_3] \) need not (and in fact, do not) extend to \( G_\mathbb{Q} \), it is necessary to replace the \( \mathbb{Z}_p[G_r][G_\mathbb{Q}] \)-module \( H^3_{\et}(X_r, \mathbb{Z}_p)^{\otimes 3}(2) \) by an appropriate twist over \( \mathbb{Q}(\zeta_r) \).

Let \( G_r \) denote the Sylow \( p \)-subgroup of the group \( \bar{G}_r \) of (2.6), and let \( G_\infty := \varprojlim G_r \). Let
\[
\Lambda(G_r) := \mathbb{Z}_p[G_r], \quad \Lambda(G_\infty) = \mathbb{Z}_p[[G_\infty]]
\]
be the finite group ring attached to \( G_r \) and the associated Iwasawa algebra, respectively.

Let \( \Lambda(G_r)(\pm \frac{1}{2}) \) denote the Galois module which is isomorphic to \( \Lambda(G_r) \) as a \( \Lambda(G_r) \)-module, and on which the Galois group \( G_\mathbb{Q}(\zeta_r) \) is made to act via its quotient \( \text{Gal}(\mathbb{Q}(\zeta_r)/\mathbb{Q}(\zeta_r)) = 1 + p\mathbb{Z}/p\mathbb{Z} \) by the element \( \sigma_m \) acting as multiplication by the group-like element \( (m, m, m) \). Let \( \Lambda(G_r)(\pm \frac{1}{2}) \) denote the projective limit of the \( \Lambda(G_r)(\pm \frac{1}{2}) \). It follows from the definitions that if
\[
\nu_{k, \ell, m} : \Lambda(G_r) \rightarrow \mathbb{Z}/p^\ell \mathbb{Z}, \quad \text{or} \quad \nu_{k, \ell, m} : \Lambda(G_\infty) \rightarrow \mathbb{Z}_p
\]
is the homomorphism sending \( a_1, a_2, a_3 \) to \( a_1^k a_2^\ell a_3^m \), then
\[
\Lambda(G_r)(\pm \frac{1}{2}) \otimes_{\nu_{k, \ell, m}} \mathbb{Z}/p^\ell \mathbb{Z} = (\mathbb{Z}/p^\ell \mathbb{Z}) \left( c_{\kappa_\text{cyc}}^{(k + \ell + m)/2} \right),
\]
where the tensor product is taken over \( \Lambda(G_r) \), and similarly for \( G_\infty \). In particular if \( k + \ell + m = 2t \) is an even integer,
\[
\Lambda(G_\infty)(\pm \frac{1}{2}) \otimes_{\nu_{k, \ell, m}} \mathbb{Z}_p = \mathbb{Z}_p(-t)(\omega^t)
\]
as \( G_\mathbb{Q} \)-modules. More generally, if \( \Omega \) is any \( \Lambda(G_\infty) \) module, write
\[
\Omega(\pm \frac{1}{2}) := \Omega \otimes_{\Lambda(G_\infty)} \Lambda(G_\infty)(\pm \frac{1}{2}), \quad \Omega(\pm \frac{1}{2}) := \Omega \otimes_{\Lambda(G_\infty)} \Lambda(G_\infty)(\pm \frac{1}{2}),
\]
for the relevant twists of \( \Omega \), which are isomorphic to \( \Omega \) as a \( \Lambda(G_\infty)[G_\mathbb{Q}(\mu_p)] \)-module but are endowed with different actions of \( G_\mathbb{Q} \).
There is a canonical Galois-equivariant $\Lambda(G_r)$-hermitian bilinear, $\Lambda(G_r)$-valued pairing

\begin{equation}
\langle , \rangle_r : H^1_{\text{ét}}(X_r, \mathbb{Z}_p)^{\otimes 3}(2)(\frac{1}{2}) \times H^1_{\text{ét}}(X_r, \mathbb{Z}_p)^{\otimes 3}(1)(\frac{1}{2}) \rightarrow \Lambda(G_r),
\end{equation}

given by the formula

\[ \langle \langle a, b \rangle \rangle_r := \sum_{\sigma = (d_1, d_2, d_3) \in G_r} \langle a^\sigma, b \rangle_{X_r} \cdot \langle d_1, d_2, d_3 \rangle, \]

where \( \langle , \rangle_r : H^1_{\text{ét}}(X_r, \mathbb{Z}_p)^{\otimes 3}(2) \times H^1_{\text{ét}}(X_r, \mathbb{Z}_p)^{\otimes 3}(1) \rightarrow H^2_{\text{ét}}(X_r, \mathbb{Z}_p(1))^{\otimes 3} = \mathbb{Z}_p \)
arises from the Poincaré duality between \( H^2_{\text{ét}}(X_r^3, \mathbb{Z}_p)(2) \) and \( H^2_{\text{ét}}(X_r^3, \mathbb{Z}_p)(1) \).

This pairing enjoys the following properties:

- For all \( \lambda \in \Lambda(G_r) \),
  \[ \langle \lambda a, b \rangle_r = \lambda^* \langle \langle a, b \rangle \rangle_r, \quad \langle a, \lambda b \rangle_r = \lambda \langle \langle a, b \rangle \rangle_r, \]

where \( \lambda^* \in \Lambda(G_r) \) is obtained from \( \lambda \) by applying the involution on the group ring which sends every group-like element to its inverse. In particular, the pairing of (2.17) can and will also be viewed as a \( \Lambda(G_r) \)-valued \( \ast \)-hermitian pairing

\[ \langle , \rangle_r : H^1_{\text{ét}}(X_r, \mathbb{Z}_p)^{\otimes 3}(2) \times H^1_{\text{ét}}(X_r, \mathbb{Z}_p)^{\otimes 3}(1) \rightarrow \Lambda(G_r). \]

- For all \( \sigma \in G_{Q(\zeta_r)} \), we have \( \langle \langle \sigma a, \sigma b \rangle \rangle_r = \langle \langle a, b \rangle \rangle_r \).
- The \( U_p \) and \( U_p^\ast \) operators are adjoint to each other under this pairing, giving rise to a duality (denoted by the same symbol, by an abuse of notation)

\[ \langle , \rangle_r : e^* H^1_{\text{ét}}(X_r, \mathbb{Z}_p)^{\otimes 3}(2)(\frac{1}{2}) \times e H^1_{\text{ét}}(X_r, \mathbb{Z}_p)^{\otimes 3}(1)(\frac{1}{2}) \rightarrow \Lambda(G_r). \]

Define

\[ \mathbb{H}^{111}(X_r) := \text{Hom}_{\Lambda(G_r)}(H^1_{\text{ét}}(X_r, \mathbb{Z}_p)^{\otimes 3}(1)(\frac{1}{2}), \Lambda(G_r)) \simeq H^1_{\text{ét}}(X_r, \mathbb{Z}_p)^{\otimes 3}(2)(\frac{1}{2}), \]

\[ \mathbb{H}^{111}_o(X_r) := \text{Hom}_{\Lambda(G_r)}(e H^1_{\text{ét}}(X_r, \mathbb{Z}_p)^{\otimes 3}(1)(\frac{1}{2}), \Lambda(G_r)) \simeq e^* H^1_{\text{ét}}(X_r, \mathbb{Z}_p)^{\otimes 3}(2)(\frac{1}{2}). \]

The above identifications of \( \mathbb{Z}_p[G_{Q(\zeta_r)}] \)-modules follow from the pairing (2.17).

To descend the field of definition of the classes \( \kappa_r[d_1, d_2, d_3] \), we package them together into elements

\[ \kappa_r[a, b, c] \in H^1(Q(\zeta_r), \mathbb{H}^{111}(X_r)) \]

indexed by triples

\begin{equation}
[a, b, c] \in I_1 = (\mathbb{Z}/p\mathbb{Z})^3 = \mu_{p-1}(\mathbb{Z}_p)^3 \subset (\mathbb{Z}_p^\times)^3.
\end{equation}

The class \( \kappa_r[a, b, c] \) is defined by setting, for all \( \sigma \in G_{Q(\zeta_r)} \) and all \( \gamma_r \in H^1_{\text{ét}}(X_r, \mathbb{Z}_p)^{\otimes 3}(1) \),

\begin{equation}
\kappa_r[a, b, c](\sigma)(\gamma_r) = \langle \langle \kappa_r[a, b, c]|(\sigma), \gamma_r \rangle \rangle_r,
\end{equation}

where the elements \( a, b, c \in (\mathbb{Z}/p\mathbb{Z})^\times \) are viewed as elements of \( (\mathbb{Z}/p^\times\mathbb{Z})^\times \) via the Teichmuller lift alluded to in (2.18). Note that there is a natural identification

\[ H^1(Q(\zeta_r), \mathbb{H}^{111}(X_r)) = \text{Ext}^1_{\Lambda(G_r)}(G_{Q(\zeta_r)})(H^1_{\text{ét}}(X_r, \mathbb{Z}_p)^{\otimes 3}(1), \Lambda(G_r)), \]
because $H_{\text{et}}^1(\overline{X}_r, \mathbb{Z}_p)^{\otimes 3}(1) = H_{\text{et}}^1(\overline{X}_r, \mathbb{Z}_p)^{\otimes 3}(1) \left( \frac{1}{2} \right)$ as $G_{\mathbb{Q}(\zeta)}$-modules and the $\Lambda(G_r)$-dual of the latter is $\mathbb{H}^{111}(X_r)$. With these definitions we have

**Lemma 2.6.** The class $\kappa_r[a, b, c]$ is the restriction to $G_{\mathbb{Q}(\zeta)}$ of a class $\kappa_r[a, b, c] \in H^1(\mathbb{Q}(\zeta_1), \mathbb{H}^{111}(X_r)) = \text{Ext}^1_{\Lambda(G_r)[G_{\mathbb{Q}(\zeta_1)}]}(H_{\text{et}}^1(\overline{X}_r, \mathbb{Z}_p)^{\otimes 3}(1) \left( \frac{1}{2} \right), \Lambda(G_r))$.

Furthermore, for all $m \in \mu_{p-1}(\mathbb{Z}_p)$,

$$
\sigma_m \kappa_r[a, b, c] = \kappa_r[ma, mb, mc].
$$

**Démonstration.** We will prove this by giving a more conceptual description of the cohomology class $\kappa_r[a, b, c]$. Let $|\Delta|$ denote the support of an algebraic cycle $\Delta$, and let

(2.20) $\Delta^\circ_r[a, b, c] := |\Delta^\circ_r[a, b, c]| \times_{X^3_1} X^3_r$

denote the inverse image in $X^3_r$ of $|\Delta^\circ_r[a, b, c]|$, which fits into the cartesian diagram

\[
\begin{array}{ccc}
\Delta^\circ_r[a, b, c] & \subseteq & X^3_r \\
\downarrow & & \downarrow \\
|\Delta^\circ_r[a, b, c]| & \subseteq & X^3_r. 
\end{array}
\]

As in the proof of Lemma 2.1, observe that

$$
\Delta^\circ_r[a, b, c] = \bigsqcup_{[d_1, d_2, d_3] \in I^1_r} |\Delta^\circ_r[ad_1, bd_2, cd_3]|
$$

where $I^1_r$ denotes the $p$-Sylow subgroup of $I_r$. Consider now the commutative diagram of $\Lambda(G_r)[G_{\mathbb{Q}(\zeta_1)}]$-modules with exact rows:

(2.21) \[
\begin{array}{ccc}
\Lambda(G_r)(\frac{-1}{2}) & \xrightarrow{j} & H^3_{\text{et}}(\overline{X}^3_r, \mathbb{Z}_p)(2) \xrightarrow{\delta} H^3_{\text{et}}(\overline{X}^3_r - \Delta^\circ_r[a, b, c], \mathbb{Z}_p)(2) \xrightarrow{\delta} H^0_{\text{et}}(\overline{\Delta}^\circ_r[a, b, c], \mathbb{Z}_p)_0 \\
\downarrow p & & \downarrow \\
H^1_{\text{et}}(\overline{X}_r, \mathbb{Z}_p)^{\otimes 3}(2) & & 
\end{array}
\]

where

- the map $j$ is the inclusion defined on group-like elements by
  \[
  j((d_1, d_2, d_3)) = \text{cl}(\Delta^\circ_r[ad_2d_3, bd_1d_3, cd_1d_2]),
  \]
  which is $G_{\mathbb{Q}(\zeta)}$-equivariant by Lemma 2.2;

- the middle row arises from the excision exact sequence in étale cohomology (cf. [388, (3.6)] and [M, p. 108]);

- the subscript of 0 appearing in the rightmost term in the exact sequence denotes the kernel of the cycle class map, i.e.,

$$
H^0_{\text{et}}(\overline{\Delta}^\circ_r[a, b, c], \mathbb{Z}_p)_0 := \ker (H^0_{\text{et}}(\overline{\Delta}^\circ_r[a, b, c], \mathbb{Z}_p)_0 \xrightarrow{\delta} H^1_{\text{et}}(\overline{X}^3_r, \mathbb{Z}_p)(2)),
$$

= ker $(H^0_{\text{et}}(\overline{\Delta}^\circ_r[a, b, c], \mathbb{Z}_p)_0)$.
and the fact that the image of $j$ is contained in $H^0_{\text{et}}(\overline{\Delta}_{\ell}^n[[a, b, c]], \mathbb{Z}_p)_0$
follows from Lemma 2.5;
— the projection $p$ is the one arising from the Künneth decomposition.
Taking the pushout and pullback of the extension in (2.21) via the maps $p$
and $j$ yields an exact sequence of $\Lambda(G_r)[\mathbb{G}(\zeta_1)]$-modules
\[
(2.22) \quad 0 \longrightarrow H^1_{\text{et}}(\overline{X}_r, \mathbb{Z}_p)^{\otimes 3}(2) \longrightarrow E_r \longrightarrow \Lambda(G_r)(\overline{1}_{2}) \longrightarrow 0.
\]
Taking the $\Lambda(G_r)$-dual of this exact sequence, we obtain
\[
0 \longrightarrow \Lambda(G_r)(\overline{1}_{2}) \longrightarrow E^*_r \longrightarrow H^1_{\text{et}}(\overline{X}_r, \mathbb{Z}_p)^{\otimes 3}(1)^* \longrightarrow 0.
\]
where $M^*$ means the $\Lambda(G_r)$-module obtained from $M$ by letting act $\Lambda(G_r)$
on it by composing with the involution $\lambda \mapsto \lambda^*$. Twisting this sequence by
$\overline{1}_{2}$ and noting that $M^*(\overline{1}_{2}) \simeq M(\overline{1}_{2})^*$ yields an extension
\[
(2.23) \quad 0 \longrightarrow \Lambda(G_r) \longrightarrow E^*_{\ell} \longrightarrow H^1_{\text{et}}(\overline{X}_r, \mathbb{Z}_p)^{\otimes 3}(1)(\overline{1}_{2})^* \longrightarrow 0.
\]
Since
\[
H^1_{\text{et}}(\overline{X}_r, \mathbb{Z}_p)^{\otimes 3}(1)(\overline{1}_{2})^* = \text{Hom}_{\Lambda(G_r)}(H^1_{\text{et}}(\overline{X}_r, \mathbb{Z}_p)^{\otimes 3}(2)(\overline{1}_{2}), \Lambda(G_r)),
\]
follows that the cohomology class realizing the extension $E_{\ell}^*$ is an element of
\[
H^1(\mathbb{Q}(\zeta_1), \text{Hom}_{\Lambda(G_r)}(H^1_{\text{et}}(\overline{X}_r, \mathbb{Z}_p)^{\otimes 3}(1)(\overline{1}_{2}), \Lambda(G_r))) = H^1(\mathbb{Q}(\zeta_1), \mathbb{H}^{111}(X_r)),
\]
because the duality afforded by $\langle , \rangle_{\ell}$ is hermitian (and not $\Lambda$-linear).
When restricted to $G_{\mathbb{Q}(\zeta_1)}$, this class coincides with $\kappa_{\ell}[a, b, c]$, and the first assertion follows.

The second assertion is an immediate consequence of the definitions, using
the Galois equivariance properties of the cycles $\Delta_r[a_1, a_2, d]_3$ given in the first assertion of Lemma 2.2.  \hfill \Box

Remark 2.7. The extension $E_{\ell}^*$ of (2.23) can also be realised as a subquotient of
the étale cohomology group $H^3_{\text{et}}(\overline{X}_r^3-\Delta_r^3[[a, b, c]], \mathbb{Z}_p)(1)$ with compact supports, in light of the Poincaré duality
\[
H^3_{\text{et}}(\overline{X}_r^3-\Delta_r^3[[a, b, c]], \mathbb{Z}_p)(2) \times H^3(\overline{X}_r^3-\Delta_r^3[[a, b, c]], \mathbb{Z}_p)(1) \longrightarrow \mathbb{Z}_p.
\]
2.3. $\Lambda$-adic cohomology classes. Thanks to Lemma 2.6, we now dispose, for each $[a, b, c] \in \mu_{p-1}(\mathbb{Z}_p)^3$, of a system
\[
(2.24) \quad \kappa_r[a, b, c] \in H^1(\mathbb{Q}(\zeta_1), \mathbb{H}^{111}(X_r))
\]
of cohomology classes indexed by the integers $r \geq 1$, so that $e^*\kappa_r[a, b, c] \in H^1(\mathbb{Q}(\zeta_1), \mathbb{H}_{\rho}^{111}(X_r))$.
Let
\[
p_{r+1, r} : \Lambda(G_{r+1}) \longrightarrow \Lambda(G_r)
\]
be the projection on finite group rings induced from the natural homomorphism $G_{r+1} \longrightarrow G_r$.

Lemma 2.8. Let $\gamma_{r+1} \in H^1_{\text{et}}(\overline{X}_{r+1}, \mathbb{Z}_p)^{\otimes 3}(1)$ and $\gamma_r \in H^1_{\text{et}}(\overline{X}_r, \mathbb{Z}_p)^{\otimes 3}(1)$ be elements that are compatible under the pushforward by $\varpi_1^3$, i.e., that satisfy
$(\varpi_1^3)_*(\gamma_{r+1}) = \gamma_r$. For all $\sigma \in G_{\mathbb{Q}(\zeta_1)}$,
\[
p_{r+1, r}(\kappa_{r+1}[a, b, c]((\sigma)\gamma_{r+1})) = \kappa_r[a, b, c]((\sigma)\gamma_r).
\]
Démonstration. This amounts to the statement that
\[ p_{r+1,r}(\langle \kappa_{r+1}[a,b,c], \gamma_{r+1} \rangle_{r+1}) = \langle \kappa_r[a,b,c], \gamma_r \rangle_r. \]
But the left-hand side of this equation is equal to
\[ \sum_{G_r} \langle (\mu^3)^*(\mu^3)_* \kappa_{r+1}[ad_2d_3, bd_1d_3, cd_1d_2], \gamma_{r+1} \rangle_{X_{r+1}} \cdot \langle d_1, d_2, d_3 \rangle, \]
where the sum runs over \( \langle d_1, d_2, d_3 \rangle \in G_r \) and \( \langle d'_1, d'_2, d'_3 \rangle \) denotes an (arbitrary) lift of \( \langle d_1, d_2, d_3 \rangle \) to \( G_{r+1} \). The third assertion in Lemma 2.4 allows us to rewrite this as
\[ \sum_{G_r} \langle (\omega_1^3)^* \kappa_r[ad_2d_3, bd_1d_3, cd_1d_2], \gamma_{r+1} \rangle_{X_r} \cdot \langle d_1, d_2, d_3 \rangle \]
\[ = \sum_{G_r} \langle \kappa_r[ad_2d_3, bd_1d_3, cd_1d_2], (\omega_1^3)_* \gamma_{r+1} \rangle_{X_r} \cdot \langle d_1, d_2, d_3 \rangle \]
\[ = \sum_{G_r} \langle \kappa_r[ad_2d_3, bd_1d_3, cd_1d_2], \gamma_r \rangle_{X_r} \cdot \langle d_1, d_2, d_3 \rangle \]
\[ = \langle \kappa_r[a,b,c], \gamma_r \rangle_r, \]
and the result follows. \( \square \)

Define
\[ (2.25) \mathbb{H}^{111}(X^*_\infty) := \text{Hom}_{\Lambda(G_{\infty})}(H^1_\text{ét}(X^*_\infty, \mathbb{Z}_p)^{\otimes 3}(1), \Lambda(G_{\infty})) \]
\[ = \text{Hom}_{\Lambda(G_{\infty})}(H^1_\text{ét}(X_1, \mathcal{L}_X^{\infty})^{\otimes 3}(1), \Lambda(G_{\infty})), \]
where the identification follows from (1.19).

Thanks to Lemma 2.8, the classes \( \kappa_r[a,b,c] \) can be packaged into a compatible collection. Namely :

Definition 2.9. Set
\[ (2.26) \kappa_\infty[a,b,c] := (\kappa_r[a,b,c])_{r \geq 1} \in H^1(\mathbb{Q}(\zeta_3), \mathbb{H}^{111}(X^*_\infty)). \]

It will also be useful to replace the classes \( \kappa_\infty[a,b,c] \) by elements that are essentially indexed by triples
\[ (\omega_1, \omega_2, \omega_3) : (\mathbb{Z}/p\mathbb{Z})^3 \rightarrow \mathbb{Z}_p^\times \]
of tame characters of \( G_r/G_r \). Assume that the product \( \omega_1 \omega_2 \omega_3 \) is an even character. This assumption is equivalent to requiring that
\[ \omega_1 \omega_2 \omega_3 = \delta^2, \quad \text{for some } \delta : (\mathbb{Z}/p\mathbb{Z})^\times \rightarrow \mathbb{Z}_p^\times. \]

Note that for a given \( (\omega_1, \omega_2, \omega_3) \), there are in fact two characters \( \delta \) as above, which differ by the unique quadratic character of conductor \( p \). With the choices of \( \omega_1, \omega_2, \omega_3 \) and \( \delta \) in hand, we set
\[ (2.27) \kappa_\infty(\omega_1, \omega_2, \omega_3; \delta) := \frac{p^3}{(p-1)^2} \cdot \sum_{[a,b,c]} \delta^{-1}(abc) \cdot \omega_1(a) \omega_2(b) \omega_3(c) \cdot \kappa_\infty[bc, ac, ab], \]
where the sum is taken over the triples \( [a, b, c] \) of \( (p-1)^{st} \) roots of unity in \( \mathbb{Z}_p^\times \). The classes \( \kappa_\infty(\omega_1, \omega_2, \omega_3; \delta) \) satisfy the following properties.
Lemma 2.10. For all $\sigma_m \in \text{Gal}(\mathbb{Q}(\zeta_{\infty})/\mathbb{Q})$,
\[\sigma_m \kappa_\infty(\omega_1, \omega_2, \omega_3; \delta) = \delta(m) \kappa_\infty(\omega_1, \omega_2, \omega_3; \delta).\]

For all diamond operators $(a_1, a_2, a_3) \in \mu_{p-1}(\mathbb{Z}_p)^3$
\[\langle a_1, a_2, a_3 \rangle \kappa_\infty(\omega_1, \omega_2, \omega_3; \delta) = \omega_{123}(a_1, a_2, a_3) \cdot \kappa_\infty(\omega_1, \omega_2, \omega_3; \delta).\]

Démonstration. This follows from a direct calculation based on the definitions, using the compatibilities of Lemma 2.2 satisfied by the cycles $\Delta_r[d_1, d_2, d_3]$. \(\square\)

The classes $\kappa_\infty[a, b, c]$ and $\kappa_\infty(\omega_1, \omega_2, \omega_3; \delta)$ are called the $\Lambda$-adic cohomology classes attached to the triple $[a, b, c] \in \mu_{p-1}(\mathbb{Z}_p)^3$ or the quadruple $(\omega_1, \omega_2, \omega_3; \delta)$. As will be explained in the next section, they are three variable families of cohomology classes parametrised by points in the triple product $W \times W \times W$ of weight spaces, and taking values in the three-parameter family of self-dual Tate twists of the Galois representations attached to the different specialisations of a triple of Hida families.

3. Higher weight balanced specialisations

For every integer $k_0 \geq 0$ define
\[W_1^{k_0} := H^1_\ell(\mathcal{X}_1, \mathcal{H}^{k_0})\]
and recall from the combination of (1.19), (1.21) and (1.22) the specialisation map
\[
(3.1) \quad \text{sp}_{k_0}^* : H^1_\ell(\mathcal{X}_1, \mathcal{L}^*) \to W_1^{k_0}.
\]

Fix throughout this section a triple
\[k = k_0 + 2, \quad \ell = \ell_0 + 2, \quad m = m_0 + 2\]
of integers $\geq 2$ for which $k_0 + \ell_0 + m_0 = 2t$ is even. Let
\[\mathcal{H}^{k_0, \ell_0, m_0} := \mathcal{H}^{k_0} \boxtimes \mathcal{H}^{\ell_0} \boxtimes \mathcal{H}^{m_0}\]
viewed as a sheaf on $X^1_\mathbb{I}$, and
\[W_1^{k_0, \ell_0, m_0} := W_1^{k_0} \otimes W_1^{\ell_0} \otimes W_1^{m_0} (2 - t)\]

As one readily checks, the $p$-adic Galois representation $W_1^{k_0, \ell_0, m_0}$ is Kummer self-dual, i.e., there is an isomorphism of $G_{\mathbb{Q}}$-modules
\[\text{Hom}_{G_{\mathbb{Q}}}(W_1^{k_0, \ell_0, m_0}, \mathbb{Z}_p(1)) \simeq W_1^{k_0, \ell_0, m_0}\]

The specialisation maps give rise, in light of (2.16), to the triple product specialisation map
\[
(3.2) \quad \text{sp}_{k_0, \ell_0, m_0}^* := \text{sp}_{k_0}^* \boxtimes \text{sp}_{\ell_0}^* \boxtimes \text{sp}_{m_0}^* : \mathbb{H}^{111}(X^1_{\infty}) \to W_1^{k_0, \ell_0, m_0}
\]
and to the associated collection of specialised classes
\[
(3.3) \quad \kappa_1(k_0, \ell_0, m_0)[a, b, c] := \text{sp}_{k_0, \ell_0, m_0}^* (\kappa_\infty[a, b, c]) \in H^1(\mathbb{Q}(\zeta_1), W_1^{k_0, \ell_0, m_0}).
\]

Note that for $(k_0, \ell_0, m_0) = (0, 0, 0)$, it follows from the definitions (cf. e.g. the proof of Lemma 2.6) that the class $\kappa_1(k_0, \ell_0, m_0)[a, b, c]$ is simply the image under the étale Abel-Jacobi map of the cycle $\Delta_1^r[a, b, c]$.\[\square\]
The main goal of this section is to offer a similar geometric description for the above classes also when \((k, \ell, m)\) is balanced and \(k_0, \ell_0, m_0 > 0\), which we assume henceforth for the remainder of this section.

In order to do this, it shall be useful to dispose of an alternate description of the extension \((2.22)\) in terms of the étale cohomology of the (open) threefold \(X^3_1 - \Delta^\circ_1[a, b, c]\) with values in appropriate sheaves.

**Lemma 3.1.** Let \(L_r^{*,\circ3}\) denote the exterior tensor product of \(L_r^*\), over the triple product \(X^3_1\). There is a commutative diagram

\[
\begin{array}{c}
H^3_{\text{ét}}(X^3, \mathbb{Z}_p)(2) & \longrightarrow & H^3_{\text{ét}}(X^3_1 - \Delta^\circ_1[a, b, c], \mathbb{Z}_p)(2) & \longrightarrow & H^0_{\text{ét}}(\Delta^\circ_1[a, b, c], \mathbb{Z}_p) \\
\end{array}
\]

in which the leftmost maps are injective and the horizontal sequences are exact.

**Démonstration.** Recall from \((1.17)\) that

\[
L_r^{*,\circ3} = (\varpi^{-1}_1 \times \varpi^{-1}_1 \times \varpi^{-1}_1)_* \mathbb{Z}_p,
\]

where

\[
\varpi^{-1}_1 \times \varpi^{-1}_1 \times \varpi^{-1}_1 : X^3_r \longrightarrow X^3_1
\]

is defined as in \((2.2)\). The vertical isomorphisms then follow from Shapiro’s lemma and the definition of \(\Delta^\circ_1[a, b, c]\) in \((2.20)\). The horizontal sequence arises from the excision exact sequence in étale cohomology of \([J88, (3.6)]\) and \([M, \text{p. 108}]\).

**Lemma 3.2.** For all \([a, b, c] \in I_1\),

\[
H^0_{\text{ét}}(\Delta^\circ_1[a, b, c], \mathcal{H}^{k_0, \ell_0, m_0}) = \mathbb{Z}_p(t).
\]

**Démonstration.** The Clebsch-Gordan formula asserts that the space of trihomogenous polynomials in \(6 = 2 + 2 + 2\) variables of tridegree \((k_0, \ell_0, m_0)\) has a unique \(\text{SL}_2\)-invariant element, namely, the polynomial

\[
P_{k_0, \ell_0, m_0}(x_1, y_1, x_2, y_2, x_3, y_3) = \begin{vmatrix}
x_2 & y_2 \\
x_3 & y_3
\end{vmatrix}^k_0 \begin{vmatrix}
x_3 & y_3 \\
x_1 & y_1
\end{vmatrix}^\ell_0 \begin{vmatrix}
x_1 & y_1 \\
x_2 & y_2
\end{vmatrix}^m_0,
\]

where

\[
k'_0 = \frac{-k_0 + \ell_0 + m_0}{2}, \quad \ell'_0 = \frac{k_0 - \ell_0 + m_0}{2}, \quad m'_0 = \frac{k_0 + \ell_0 - m_0}{2}.
\]

Since the triplet of weights is balanced, it follows that \(k'_0, \ell'_0, m'_0 \geq 0\). From the Clebsch-Gordan formula it follows that \(H^0_{\text{ét}}(\Delta^\circ_1[a, b, c], \mathcal{H}^{k_0, \ell_0, m_0})\) is spanned by the global section whose stalk at a point \(((A, P_1), (A, P_2), (A, P_3)) \in \Delta^\circ_1[a, b, c]\) as in \((2.5)\) is given by

\[
(X_2 \otimes Y_3 - Y_2 \otimes X_3)^{\otimes k'_0} \otimes (X_1 \otimes Y_3 - Y_1 \otimes X_3)^{\otimes \ell'_0} \otimes (X_1 \otimes Y_2 - Y_1 \otimes X_2)^{\otimes m'_0},
\]

where \((X_i, Y_i), i = 1, 2, 3\), is a basis of the stalk of \(\mathcal{H}\) at the point \((A, P_i)\) in \(X_1\). The Galois action is given by the \(t\)-th power of the cyclotomic character because the Weil pairing takes values in \(\mathbb{Z}_p(1)\) and \(k'_0 + \ell'_0 + m'_0 = t\).  \(\square\)
Write $\text{cl}_{k',\ell',m'}(\Delta_1[a,b,c]) \in H^0_{\text{ét}}(\Delta_1^o[a,b,c],\mathcal{H}^{k',\ell',m'})$ for the standard generator given by Lemma 3.2. Define

\[(3.4)\quad \text{AJ}_{k',\ell',m'}(\Delta_1[a,b,c]) \in H^1(\mathbb{Q}(\zeta_1), W_{1}^{k',\ell',m'})\]

to be the extension class constructed by pulling back by $j$ and pushing forward by $p$ in the exact sequence of the middle row of the following diagram:

\[(3.5)\]

where

- $\Delta = \Delta_1[a,b,c]$;
- the map $j$ is the $G_{\mathbb{Q}(\zeta_1)}$-equivariant inclusion defined by $j(1) = \text{cl}_{k,\ell,m}(\Delta)$;
- the surjectivity of the right-most horizontal row follows from the vanishing of the group $H^3_{\text{ét}}(\bar{X}_1^{\cdot}, \mathcal{H}^k_{\cdot,\ell,\cdot,m})$, which in turn is a consequence of the Künneth formula and the vanishing of the terms $H^2_{\text{ét}}(\bar{X}_1, \mathcal{H}^k_{\cdot,\cdot,\cdot})$ when $k > 0$ (cf. [BDP13, Lemmas 2.1, 2.2]).

In particular the image of $j$ lies in the image of the right-most horizontal row and this holds regardless whether the cycle is null-homologous or not. The reader may compare this construction with (2.21), where the cycle $\Delta_1^o[a,b,c]$ is null-homologous and this property was crucially exploited.

**Theorem 3.1.** Set $\text{AJ}_{k',\ell',m'}(\Delta_1^o[a,b,c]) = \theta_q \text{AJ}_{k,\ell,m}(\Delta_1[a,b,c])$. Then the identity

$$\kappa_1(k,\ell,m)[a,b,c] = \text{AJ}_{k',\ell',m'}(\Delta_1^o[a,b,c])$$

holds in $H^1(\mathbb{Q}(\zeta_1), W_{1}^{k',\ell',m'})$.

**Démonstration.** Set $\Delta := \Delta_1^o[a,b,c]$ in order to alleviate notations. Thanks to Lemma 3.1, the diagram in (2.21) used to construct the extension $E_r$ realising the class $\kappa_r[a,b,c]$ is the same as the diagram

\[(3.6)\]

Let

$$\nu_{k',\ell',m'} : \Lambda(G_r) \longrightarrow \mathbb{Z}/p^r\mathbb{Z}$$
be the algebra homomorphism sending the group like element \( \langle d_1, d_2, d_3 \rangle \) to \( d_1^{k_1} d_2^{k_2} d_3^{m} \), and observe that the moment maps of (1.20) allow us to identify
\[
L^*_{r, \nu_0, k_0, m_0} (\mathbb{Z}/p^r \mathbb{Z}) = H_{r, k_0, m_0}.
\]

Tensoring (3.6) over \( \Lambda(G_r) \) with \( \mathbb{Z}/p^r \mathbb{Z} \) via the map \( \nu_{k_0, m_0} : \Lambda(G_r) \rightarrow \mathbb{Z}/p^r \mathbb{Z} \), yields the specialised diagram which coincides exactly with the mod \( p^r \) reduction of (3.5), with \( \Delta = \Delta^0_1[a, b, c] \). The result follows by passing to the limit with \( r \).

**Corollary 3.3.** Let
\[
\Delta^0_1(\omega_1, \omega_2, \omega_3; \delta) := \frac{p^3}{(p-1)^3} \cdot \sum_{[a,b,c] \in F_1} \delta^{-1}(abc)\omega_1(a)\omega_2(b)\omega_3(c)\Delta^0_1[a, b, c].
\]

Then
\[
sp^*_k, k_0, m_0(\kappa_{\infty}(\omega_1, \omega_2, \omega_3; \delta)) = \Lambda_j k_0, k_0, m_0(\Delta^0_1(\omega_1, \omega_2, \omega_3; \delta)).
\]

**Démonstration.** This follows directly from the definitions. \( \square \)

### 4. Cristalline specialisations

Let \( f, g, h \) be three arbitrary primitive, residually irreducible \( p \)-adic Hida families of tame levels \( M_f, M_g, M_h \) and tame characters \( \chi_f, \chi_g, \chi_h \), respectively, with associated weight space \( W_f \times W_g \times W_h \). Assume \( \chi_f \chi_g \chi_h = 1 \) and set \( M = \text{lcm}(M_f, M_g, M_h) \). Let \( (x, y, z) \in W_f \times W_g \times W_h \) be a point lying above a classical triple \( (\nu_{k_0, \varepsilon_1}, \nu_{k_0, \varepsilon_2}, \nu_{k_0, \varepsilon_3}) \in W^3 \) of weight space. As in Definition 1.2, the point \( (x, y, z) \) is said to be **tamely ramified** if the three characters \( \varepsilon_1, \varepsilon_2 \) and \( \varepsilon_3 \) are tamely ramified, i.e., factor through the quotient \( (\mathbb{Z}/p \mathbb{Z})^\times \) of \( \mathbb{Z}_p^\times \), and is said to be **crystalline** if \( \varepsilon_1 \omega^{-k_0} = \varepsilon_2 \omega^{-\ell_0} = \varepsilon_3 \omega^{-m_0} = 1 \).

Fix such a crystalline point \( (x, y, z) \) of balanced weight \( (k, \ell, m) = (k_0 + 2, \ell_0 + 2, m_0 + 2) \), and let \( (f_x, g_y, h_z) \) be the specialisations of \( (f, g, h) \) at \( (x, y, z) \). The ordinariness hypothesis implies that, for all but finitely many exceptions, these eigenforms are the \( p \)-stabilisations of newforms of level dividing \( M \), denoted \( f, g \) and \( h \) respectively:

\[
f_x(q) = f(q) - \beta f(q^p), \quad g_y = g(q) - \beta g(q^p), \quad h_z(q) = h(q) - \beta_h h(q^p).
\]

Since the point \( (x, y, z) \) is fixed throughout this section, the dependency of \( (f, g, h) \) on \( (x, y, z) \) has been suppressed from the notations, and we also write \( (f_x, g_y, h_z) := (f_x, g_y, h_z) \) for the ordinary \( p \)-stabilisations of \( f, g \) and \( h \).

Recall the quotient \( X_{01} \) of \( X_1 \), having \( \Gamma_0(p) \)-level structure at \( p \), and the projection map \( \mu : X_1 \rightarrow X_{01} \) introduced in (1.15). By an abuse of notation, the symbol \( H^{k_0} \) is also used to denote the étale sheaves appearing in (1.4) over any quotient of \( X_1 \), such as \( X_{01} \). Let
\[
W_1 := H^{k_0}_{\text{ét}}(X_1, H^{k_0}) \otimes H^1_{\text{ét}}(X_1, H^{k_0}) \otimes H^1_{\text{ét}}(X_1, H^{m_0})(2-t),
\]
\[
W_{01} := H^{k_0}_{\text{ét}}(X_{01}, H^{k_0}) \otimes H^1_{\text{ét}}(X_{01}, H^{k_0}) \otimes H^1_{\text{ét}}(X_{01}, H^{m_0})(2-t),
\]
be the Galois representations arising from the cohomology of $X_1$ and $X_{01}$ with values in these sheaves. They are endowed with a natural action of the triple tensor product of the Hecke algebras of weight $k$, $\ell$, $m$ and level $Mp$.

Let $W_1[\alpha, g_\alpha, h_\alpha]$ denote the $(f_\alpha, g_\alpha, h_\alpha)$-isotypic component of $W_1$ on which the Hecke operators act with the same eigenvalues as on $f_\alpha \otimes g_\alpha \otimes h_\alpha$. Let $\pi_{f_\alpha, g_\alpha, h_\alpha} : W_1 \to W_1[\alpha, g_\alpha, h_\alpha]$ denote the associated projection. Use similar notations for $W_{01}$.

Recall the family
\[
\kappa_\infty(\epsilon_1\omega^{-k}, \epsilon_2\omega^{-\ell}, \epsilon_3\omega^{-m}; 1) = \kappa_\infty(1, 1, 1; 1)
\]
that was introduced in (2.27). By Lemma 2.10, this class lies in $H^1(Q_\infty, \mathbb{H}^{111}(X_{01}^\infty))$.

Recall the choice of auxiliary prime $q$ made in the definition of the modified diagonal cycle (2.14). We assume now that $q$ is chosen so that $C_q := (a_q(f) - q - 1)(a_q(g) - q - 1)(a_q(h) - q - 1)$ is a $p$-adic unit. Note that this is possible because the Galois representations $\pi_q$, $\pi_k$ and $\pi_h$ were assumed to be residually irreducible and hence $f$, $g$ and $h$ are non-Eisenstein mod $p$.

Let
\[
\kappa(\alpha, g_\alpha, h_\alpha) := \frac{1}{C_q} \cdot \pi_{f_\alpha, g_\alpha, h_\alpha} sp^* x_{g, z} \kappa_\infty(1, 1, 1; 1) \in H^1(Q, W_1[\alpha, g_\alpha, h_\alpha])
\]
be the specialisation at the crystalline point $(x, y, z)$ of (4.1), after projecting it to the $(f_\alpha, g_\alpha, h_\alpha)$-isotypic component of $W_1$ via $\pi_{f_\alpha, g_\alpha, h_\alpha}$. We normalize the class by multiplying it by the above constant in order to remove the dependency on the choice of $q$.

The main goal of this section is to relate this class to the generalised Gross-Schoen diagonal cycles that were studied in [DR14], arising from cycles in Kuga-Sato varieties which are fibered over $X^3$ and have good reduction at $p$.

The fact that $(x, y, z)$ is a crystalline point implies that the diamond operators in $\text{Gal}(X_1/X_{01})$ act trivially on the $(f_\alpha, g_\alpha, h_\alpha)$-eigencomponents, and hence the Hecke-equivariant projection $\mu^* : W_1 \to W_{01}$ induces an isomorphism
\[
\mu^* : W_1[\alpha, g_\alpha, h_\alpha] \to W_{01}[\alpha, g_\alpha, h_\alpha].
\]

The first aim is to give a geometric description of the class
\[
\kappa_{01}(\alpha, g_\alpha, h_\alpha) := \mu^* \kappa(\alpha, g_\alpha, h_\alpha)
\]
in terms of appropriate algebraic cycles. To this end, recall the cycles $\Delta_1[a, b, c] \in \text{CH}^2(X_1^3)$ introduced in (2.4), and let $p^* := \pm p$ be such that $Q(\sqrt{p^*})$ is the quadratic subfield of $Q(\zeta_1)$.

**Lemma 4.1.** The cycle $\mu^* \Delta_1[a, b, c]$ depends only on the quadratic residue symbol $(abc)_p$ attached to $abc \in (\mathbb{Z}/p\mathbb{Z})^\times$. The cycles
\[
\Delta_1^+ := \mu^* \Delta_1[a, b, c] \quad \text{for any } a, b, c \text{ with } \left(\frac{abc}{p}\right) = 1,
\]
\[
\Delta_1^- := \mu^* \Delta_1[a, b, c] \quad \text{for any } a, b, c \text{ with } \left(\frac{abc}{p}\right) = -1,
\]
belong to $\text{CH}^2(X_{01}^3/Q(\sqrt{p^*}))$ and are interchanged by the non-trivial automorphism of $Q(\sqrt{p^*})$. 
Démonstration. Arguing as in Lemma 2.2 shows that for all $(d_1, d_2, d_3) \in I_1 = (\mathbb{Z}/p\mathbb{Z})^3$,
\[ \langle d_1, d_2, d_3 \rangle \Delta_1[a, b, c] = \Delta_1[d_2d_3a, d_1d_3b, d_3d_2c]. \]
The orbit of the triple $[a, b, c]$ under the action of $I_1$ is precisely the set of triples $[a', b', c']$ for which $(d_1' d_2') = (d_1 d_2)$. Since $X_{01}$ is the quotient of $X_1$ by the group $I_1$, it follows that $\mu^3 \Delta_1[a, b, c]$ depends only on this quadratic residue symbol, and hence that the classes $\Delta_0^+$ and $\Delta_0^-$ in the statement of Lemma 4.1 are well-defined. Furthermore, Lemma 2.6 implies that, for all $m \in (\mathbb{Z}/p\mathbb{Z})^\times$, the Galois automorphism $\sigma_m$ fixes $\Delta_0^+$ and $\Delta_0^-$ if $m$ is a square modulo $p$, and interchanges these two cycle classes otherwise. It follows that they are invariant under the Galois group $\text{Gal}(\mathbb{Q}(\zeta_1)/\mathbb{Q}(\sqrt{p}))$ and hence descend to a pair of conjugate cycles $\Delta_0^\pm$ defined over $\mathbb{Q}(\sqrt{p})$, as claimed.

It follows from this lemma that the algebraic cycle
\[ \Delta_{01} := \Delta_0^+ + \Delta_0^- \in \text{CH}^2(X_{01}/\mathbb{Q}). \]
is defined over $\mathbb{Q}$. To describe it concretely, note that a triple $(C_1, C_2, C_3)$ of distinct cyclic subgroups of order $p$ in an elliptic curve $A$ admits a somewhat subtle discrete invariant in $(\mu_p^\otimes - \{1\})$ modulo the action of $(\mathbb{Z}/p\mathbb{Z})^\times$, denoted $o(C_1, C_2, C_3)$ and called the orientation of $(C_1, C_2, C_3)$. This orientation is defined by choosing generators $P_1, P_2, P_3$ of $C_1, C_2$ and $C_3$ respectively and setting
\[ o(C_1, C_2, C_3) := \langle P_2, P_3 \rangle \otimes \langle P_3, P_1 \rangle \otimes \langle P_1, P_2 \rangle \in \mu_p^\otimes - \{1\}. \]
It is easy to check that the value of $o(C_1, C_2, C_3)$ in $\mu_p^\otimes - \{1\}$ only depends on the choices of generators $P_1, P_2$ and $P_3$, up to multiplication by a non-zero square in $(\mathbb{Z}/p\mathbb{Z})^\times$. In view of (2.5), we then have
\[ \Delta_{01} = \{(A, C_1), (A, C_2), (A, C_3)\} \quad \text{with} \quad C_1 \neq C_2 \neq C_3, \]
and
\[ \Delta_0^+ = \{(A, C_1), (A, C_2), (A, C_3)\} \quad \text{with} \quad o(C_1, C_2, C_3) = a_1^\otimes, \quad a \in (\mathbb{Z}/p\mathbb{Z})^\times, \]
\[ \Delta_0^- = \{(A, C_1), (A, C_2), (A, C_3)\} \quad \text{with} \quad o(C_1, C_2, C_3) = a_1^-\otimes, \quad a \notin (\mathbb{Z}/p\mathbb{Z})^\times. \]

Recall the natural projections
\[ \pi_1, \pi_2 : X_{01} \longrightarrow X, \quad \varpi_1, \varpi_2 : X_1 \longrightarrow X \]
to the curve $X = X_0(M)$ of prime to $p$ level, and set
\[ W_0 := H^1_{\text{et}}(X_0, \mathcal{H}^\kappa) \otimes H^1_{\text{et}}(X_0, \mathcal{H}^\ell) \otimes H^1_{\text{et}}(X_0, \mathcal{H}^m)(2 - t). \]
The Galois representation $W_0$ is endowed with a natural action of the triple tensor product of the Hecke algebras of weight $k_\gamma, \ell, m_\gamma$ and level $M$. Let $W_0[f, g, h]$ denote the $(f, g, h)$-isotypic component of $W_0$, on which the Hecke operators act with the same eigenvalues as on $f \otimes g \otimes h$. Note that the $U^*_p$ operator does not act naturally on $W_0$ and hence one cannot speak of the $(f_\alpha, g_\alpha, h_\alpha)$-eigenspace of this Hecke module. One can, however, denote by $W_1[f, g, h]$ and $W_0[f, g, h]$ the $(f, g, h)$-isotypic component of these Galois representations, in which the action of the $U^*_p$ operators on the three factors are not taken into account. Thus, $W_0[f, g, h]$
under the ordinary projection, and likewise for $W_1$. In other words, denoting by $\pi_{f,g,h}$ the projection to the $(f,g,h)$-isotypic component on any of these modules, one has

$$\pi_{f_0,g_0,h_0} = e^* \pi_{f,g,h}$$

whenever the left-hand projection is defined.

The projection maps

$$(\pi_1, \pi_1, \pi_1) : X_{01}^3 \longrightarrow X^3, \quad (\varpi_1, \varpi_1, \varpi_1) : X_{1}^3 \longrightarrow X^3$$

induces push-forward maps

$$(\pi_1, \pi_1, \pi_1)_* : W_{01}[f_0,g_0,h_0] \longrightarrow W_0[f,g,h],$$

$$(\varpi_1, \varpi_1, \varpi_1)_* : W_1[f_0,g_0,h_0] \longrightarrow W_0[f,g,h]$$

on cohomology, as well as maps on the associated Galois cohomology groups.

The goal is now to relate the class

$$(4.5) \quad (\varpi_1, \varpi_1, \varpi_1)_*(\kappa(f_0, g_0, h_0)) = (\pi_1, \pi_1, \pi_1)_*(\kappa_{01}(f_0, g_0, h_0))$$

to those arising from the diagonal cycles on the curve $X_0 = X$, whose level is prime to $p$.

To do this, it is key to understand how the maps $\pi_{1*}$ and $(\pi_1, \pi_1, \pi_1)_*$ interact with the Hecke operators, especially with the ordinary and anti-ordinary projectors $e$ and $e^*$, which do not act naturally on the target of $\pi_{1*}$. Consider the map

$$(\pi_1, \pi_2) : W_{01}^{k} : H^1_{\text{ét}}(\bar{X}_{01}, \mathcal{H}^{k}) \longrightarrow W_0^{k} := H^1_{\text{ét}}(\bar{X}_0, \mathcal{H}^{k}).$$

It is compatible in the obvious way with the good Hecke operators arising from primes $\ell \nmid Mp$, and therefore induces a map

$$(4.6) \quad (\pi_1, \pi_2) : W_{01}^{k} [f] \longrightarrow W_0^{k} [f] \oplus W_0^{k} [f]$$

on the $f$-isotypic components for this Hecke action. As before, note that $W_{01}^{k} [f]$ is a priori larger than $W_0^{k} [f_0]$, which is its ordinary quotient.

Let $\xi_f := \chi_f(p)^{k-1}$ be the determinant of the frobenius at $p$ acting on the two-dimensional Galois representation attached to $f$, and likewise for $g$ and $h$.

Lemma 4.2. For the map $(\pi_1, \pi_2)$ as in (4.6),

$$(\pi_1)_* \circ U_p = \begin{pmatrix} a_p(f) & 0 \\ \xi_f & 0 \end{pmatrix} \begin{pmatrix} \pi_1 \\ \pi_2 \end{pmatrix},$$

$$(\pi_1)_* \circ U_p^* = \begin{pmatrix} 0 & -\xi_f p^{k-1} \\ -\xi_f p^{k-1} & a_p(f) \end{pmatrix} \begin{pmatrix} \pi_1 \\ \pi_2 \end{pmatrix}.$$
For the next calculations, it shall be notationally convenient to introduce the notations

\[ \delta_f = \alpha_f - \beta_f, \quad \delta_g = \alpha_g - \beta_g, \quad \delta_h = \alpha_h - \beta_h, \quad \delta_{fgh} = \delta_f \delta_g \delta_h. \]

**Lemma 4.3.** For \((\pi_1, \pi_2)\) as in Lemma 4.2,

\[ \pi_1 \circ e = \frac{\alpha_f \pi_1 - \pi_2}{\delta_f}, \quad \pi_2 \circ e = \frac{\xi_f \pi_1 - \beta_f \pi_2}{\delta_f} = \beta_f \cdot (\pi_1 \circ e), \]

\[ \pi_1 \circ e^* = \frac{-\beta_f \pi_1 + p \pi_2}{\delta_f}, \quad \pi_2 \circ e^* = \frac{-\xi_f p^{-1} \pi_1 + \alpha_f \pi_2}{\delta_f} = po_f^{-1} \cdot (\pi_1 \circ e^*). \]

**Démonstration.** The matrix identities

\[
\begin{pmatrix}
\alpha_p(f) & -1 \\
\xi_f & 0
\end{pmatrix} = \begin{pmatrix}
1 & 1 \\
\beta_f & \alpha_f
\end{pmatrix} \begin{pmatrix}
\alpha_f & 0 \\
0 & \beta_f
\end{pmatrix} \begin{pmatrix}
1 & 1 \\
\beta_f & \alpha_f
\end{pmatrix}^{-1},
\]

\[
\begin{pmatrix}
0 & p \\
-\xi_f p^{-1} \alpha_p(f)
\end{pmatrix} = \begin{pmatrix}
\beta_f & \alpha_f \\
\xi_f p^{-1} & \xi_f p^{-1}
\end{pmatrix} \begin{pmatrix}
\alpha_f & 0 \\
0 & \beta_f
\end{pmatrix} \begin{pmatrix}
\beta_f & \alpha_f \\
\xi_f p^{-1} & \xi_f p^{-1}
\end{pmatrix}^{-1},
\]

show that

\[
\lim \left( \begin{pmatrix}
\alpha_p(f) & -1 \\
\xi_f & 0
\end{pmatrix} \right)^n = \left( \begin{pmatrix}
1 & 1 \\
\beta_f & \alpha_f
\end{pmatrix} \begin{pmatrix}
1 & 0 \\
0 & 1
\end{pmatrix} \begin{pmatrix}
1 & 1 \\
\beta_f & \alpha_f
\end{pmatrix} \right)^{-1},
\]

\[
\lim \left( \begin{pmatrix}
0 & p \\
-\xi_f p^{-1} \alpha_p(f)
\end{pmatrix} \right)^n = \delta_f^{-1} \begin{pmatrix}
\alpha_f & -1 \\
\xi_f & -\beta_f
\end{pmatrix},
\]

and the result now follows from Lemma 4.2.

**Lemma 4.4.** Let \(\kappa \in H^1(\mathbb{Q}, W_{01}[f, g, h])\) be any cohomology class with values in the \((f, g, h)\)-isotypic subspace of \(W_{01}\), and let \(e, e^* : H^1(\mathbb{Q}, W_{01}[f, g, h]) \to H^1(\mathbb{Q}, W_{01}[f, g, h])\) denote the ordinary and anti-ordinary projections. Then

\[
(\pi_1, \pi_1, \pi_1) \cdot (e \kappa) = \delta_{fgh}^{-1} \times \left\{ \alpha_f \alpha_g \alpha_h (\pi_1, \pi_1, \pi_1)^* - \alpha_g \alpha_h (\pi_2, \pi_1, \pi_1)^* - \alpha_f \alpha_g (\pi_1, \pi_2, \pi_1)^* + \alpha_f (\pi_1, \pi_2, \pi_2)^* + \alpha_g (\pi_2, \pi_1, \pi_1)^* + \alpha_h (\pi_2, \pi_2, \pi_1)^* - (\pi_2, \pi_2, \pi_2)^* (\kappa) \right\},
\]

\[
(\pi_1, \pi_1, \pi_1) \cdot (e^* \kappa) = \delta_{fgh}^{-1} \times \left\{ -\beta_f \beta_g \beta_h (\pi_1, \pi_1, \pi_1)^* + \beta_f \beta_g (\pi_1, \pi_1, \pi_1)^* + p \beta_f \beta_g (\pi_1, \pi_1, \pi_1)^* + p^2 \beta_g (\pi_2, \pi_1, \pi_1)^* - p^2 \beta_f (\pi_2, \pi_1, \pi_1)^* - p^3 \beta_h (\pi_2, \pi_2, \pi_1)^* + p^3 (\pi_2, \pi_2, \pi_2)^* (\kappa),
\]

where we recall that \(\delta_{fgh} := ((\alpha_f - \beta_f)(\alpha_g - \beta_g)(\alpha_h - \beta_h)).\)

**Démonstration.** This follows directly from Lemma 4.3.
Recall the notations

\[ k_o := k - 2, \quad \ell_o = \ell - 2, \quad m_o := m - 2, \quad r := (k_o + \ell_o + m_o)/2. \]

Let \( A \) denote the Kuga-Sato variety over \( X \) as introduced in 1.2. In [DR14, Definitions 3.1,3.2 and 3.3], a generalized diagonal cycle

\[ \Delta_{k,\ell,m} = \Delta_{0}^{k,\ell,m} = \Delta_{0}^{k,\ell,m} \in \text{CH}^{r+2}(A^k \times A^\ell \times A^m, \mathbb{Q}) \]

is associated to the triple \((k,\ell,m)\).

When \( k_o,\ell_o,m_o > 0 \), \( \Delta_{k,\ell,m} \) is obtained by choosing subsets \( A, B \) and \( C \) of the set \( \{1,\ldots,r\} \) which satisfy:

\[ \#A = k_o, \quad \#B = \ell_o, \quad \#C = m_o, \quad A \cap B \cap C = \emptyset, \]

\[ \#(B \cap C) = r - k_o, \quad \#(A \cap C) = r - \ell_o, \quad \#(A \cap B) = r - m_o. \]

The cycle \( \Delta_{k,\ell,m} \) is defined as the image of the embedding \( A^r \to A^k \times A^\ell \times A^m \) given by sending \((E, (P_1,\ldots,P_r))\) to \(((E, P_A), (E, P_B), (E, P_C))\), where for instance \( P_A \) is a shorthand for the \( k_o \)-tuple of points \( P_j \) with \( j \in A \).

Let also \( \Delta_0^{k,\ell,m} \in \text{CH}^{r+2}(A^k \times A^\ell \times A^m) \) denote the generalised diagonal cycle in the product of the three Kuga-Sato varieties of weights \((k,\ell,m)\) fibered over \( X_{01} \), defined in a similar way as in (4.4) and along the same lines as recalled above.

More precisely, \( \Delta_0^{k,\ell,m} \) is defined as the schematic closure in \( A^k \times A^\ell \times A^m \) of the set of tuples \([(E, C_1, P_A), (E, C_2, P_B), (E, C_3, P_C)]\) where \( P_A, P_B, P_C \) are as above, and \( C_1, C_2, C_3 \) is a triple of pairwise distinct subgroups of order \( p \) in the elliptic curve \( E \).

Since the triple \((k_o,\ell_o,m_o)\) is fixed throughout this section, in order to alleviate notations in the statements below we shall simply denote \( \Delta^\sharp \) and \( \Delta_0^\sharp \) for \( \Delta_{k,\ell,m} \) and \( \Delta_0^{k,\ell,m} \) respectively.

**Lemma 4.5.** The following identities hold in \( \text{CH}^{r+2}(A^k \times A^\ell \times A^m) \):

\[
\begin{align*}
(p_1, p_1, p_1)_*(\Delta^\sharp_{01}) & = (p+1)p(p-1)(\Delta^\sharp), \\
(p_2, p_1, p_1)_*(\Delta^\sharp_{01}) & = p(p-1) \times (T_p, 1, 1)(\Delta^\sharp), \\
(p_1, p_2, p_1)_*(\Delta^\sharp_{01}) & = p(p-1) \times (1, T_p, 1)(\Delta^\sharp), \\
(p_1, p_1, p_2)_*(\Delta^\sharp_{01}) & = p(p-1) \times (1, 1, T_p)(\Delta^\sharp), \\
(p_1, p_2, p_2)_*(\Delta^\sharp_{01}) & = (p-1) \times ((1, T_p, T_p)(\Delta^\sharp) - p^{r-k} D_1) \\
(p_2, p_1, p_2)_*(\Delta^\sharp_{01}) & = (p-1) \times ((T_p, 1, T_p)(\Delta^\sharp) - p^{r-k} D_2) \\
(p_1, p_2, p_1)_*(\Delta^\sharp_{01}) & = (p-1) \times ((T_p, T_p, 1)(\Delta^\sharp) - p^{r-m} D_3) \\
(p_2, p_2, p_2)_*(\Delta^\sharp_{01}) & = (T_p, T_p, T_p)(\Delta^\sharp) - p^{r-k} E_1 - p^{r-\ell} E_2 - p^{r-m} E_3 \\
& - p^{r} (p+1) \Delta^\sharp,
\end{align*}
\]

where the cycles \( D_1, D_2 \) and \( D_3 \) satisfy

\[
\begin{align*}
([p], 1, 1)_*(D_1) & = p^{k}(T_p, 1, 1)_*(\Delta^\sharp), \\
(1, [p], 1)_*(D_2) & = p^{\ell}(1, T_p, 1)_*(\Delta^\sharp), \\
(1, 1, [p])_*(D_3) & = p^{m}(1, 1, T_p)(\Delta^\sharp).
\end{align*}
\]
the cycles $E_1$, $E_2$ and $E_3$ satisfy

\[(p, 1, 1)_*(E_1) = p^k(T_{p_2}, 1, 1)(\Delta^2), \quad (1, [p], 1)_*(E_2) = p^\ell(1, T_{p_2}, 1)(\Delta^2), \quad (1, 1, [p])_*(E_3) = p^{m_2}(1, 1, T_{p_2})(\Delta^2),\]

and $T_{p_2} := T_p^2 - (p + 1)[p]$. 

Démonstration. The first four identities are straightforward: the map $\pi_1 \times \pi_1 \times \pi_1$ induces a finite map from $\Delta^2_0$ to $\Delta^2$ of degree $(p + 1)p(p - 1)$, which is the number of possible choices of an ordered triple of distinct subgroups of order $p$ on an elliptic curve, and likewise $\pi_2 \times \pi_1 \times \pi_1$ induces a map of degree $p(p - 1)$ from $\Delta^2_0$ to $(T_p, 1, 1)\Delta^2$. The remaining identities follow from combinatorial reasonings based on the explicit description of the cycles $\Delta^2_0$ and $\Delta^2$. For the 5th identity, observe that $(\pi_1, \pi_2, \pi_2)_*$ induces a degree $(p - 1)$ map from $\Delta^2_0$ to the variety $X$ parametrising triples $((E, P_A), (E', P_B'), (E'', P_C'))$ for which there are distinct cyclic $p$-isogenies $\varphi' : E \to E'$ and $\varphi' : E \to E''$, the system of points $P_B \subset E'$ and $P_C' \subset E''$ indexed by the sets $B$ and $C$ satisfy

\[\varphi'(P_{A\cap B}) = \varphi'(P_{A\cap C}) = \varphi''(P_{A\cap C}) = \varphi''(P_{A\cap C}),\]

and for which there exists points $Q_{B\cap C} \subset E$ indexed by $B \cap C$ satisfying

\[\varphi'(Q_{B\cap C}) = \varphi''(Q_{B\cap C}) = \varphi''(Q_{B\cap C}).\]

On the other hand, $(1, T_p, T_p)$ parametrises triples of the same type, in which $E'$ and $E''$ need not be distinct. It follows that

\[(4.7) \quad (1, T_p, T_p)(\Delta^2) = X + p^{r-k_2}D_1,\]

where the closed points of $D_1$ correspond to triples $((E, P_A), (E', P_B'), (E'', P_C'))$ for which there is a cyclic $p$-isogeny $\varphi' : E \to E'$ satisfying

\[\varphi'(P_{A\cap B}) = \varphi'(P_{A\cap C}) = \varphi''(P_{A\cap C}).\]

The coefficient of $p^{r-k_2}$ in (4.7) arises because each closed point of $D_1$ comes from $p^\#(Q_{B\cap C})$ distinct closed points on $(1, T_p, T_p)(\Delta^2)$, obtained by translating the points $P_j \subset P_{B\cap C}$ with $j \in B \cap C$ by arbitrary elements of $\ker(\varphi)$. The fifth identity now follows after noting that the map $([p], 1, 1)_*$ induces a map of degree $p^k$ from $D_1$ to $(T_p, 1, 1)_*\Delta^2$. The 6th and 7th identity can be treated with an identical reasoning by interchanging the three factors in $W^k \times W^k \times W^{m_2}$. As for the last identity, the map $(\pi_2, \pi_2, \pi_2)_*$ induces a map of degree 1 to the variety $Y$ consisting of triples $(E', E'', E''')$ of elliptic curves which are $p$-isogenous to a common elliptic curve $E$ and distinct. But it is not hard to see that

\[(T_p, T_p, T_p)(\Delta^2) = Y + p^{r-k_2}E_1 + p^{r-\ell_2}E_2 + p^{r-m_2}E_3 + p^r(p + 1)\Delta^2\]

where the additional terms on the right hand side account for triples $(E', E'', E''')$ where $E' \neq E'' = E'''$, where $E' \neq E' = E'''$, where $E'' \neq E'' = E'''$, and where $E' = E'' = E'''$ respectively. □

Assume for the remainder of the section that $k_2, \ell_2, m_2 > 0$. Recall the projectors $\epsilon_k$ of (1.5). It was shown in [DR14, §3.1] that $(\epsilon_{k_2}, \epsilon_{\ell_2}, \epsilon_{m_2})\Delta^k, \ell_2, m_2$ is a null-homologous cycle and we may define

\[(4.8) \quad \kappa(f, g, h) := \pi_{f,g,h} AJ_{\epsilon_k}(\epsilon_{k_2}, \epsilon_{\ell_2}, \epsilon_{m_2}) \Delta^{k_2, \ell_2, m_2} \in H^1(Q, W_0[f, g, h])\]
as the image of this cycle under the $p$-adic étale Abel-Jacobi map, followed by the natural projection from $H_{\text{ét}}^{2c-1}(\bar{\mathbb{A}}^k \times \bar{\mathbb{A}}^k \times \bar{\mathbb{A}}^m, \mathbb{Q}_p(\epsilon))$ to $W_0^{k,\epsilon,m}$, induced by the Künneth decomposition and the projection $\pi_{f,g,h}$.

It follows from [DR14, (66)], (1.5) and the vanishing of the terms $H_{\text{ét}}^1(X_1, \mathcal{H}_k)$ for $i \neq 1$ when $k_1 > 0$, that the class $\kappa(f,g,h)$ is realized by the $(f,g,h)$-isotypic component of the same extension class as in (3.5), after replacing $X_1$ by the curve $X = X_0$ and $\Delta = \Delta^{0,0,0}$ is taken to be the usual diagonal cycle in $X^3$. In the notations of (3.4), this amounts to

$$(4.9) \quad \kappa(f,g,h) = \pi_{f,g,h}\text{AJ}^{k,\epsilon,m}_0(\Delta).$$

Similar statements holds over the curve $X_01$. Namely, we also have the following:

**Proposition 4.6.** The cycle $(\epsilon_k, \epsilon_\ell, \epsilon_m)\Delta^{k,\epsilon,m}_0$ is null-homologous and the following equality of classes holds in $H^1(\mathbb{Q}, W_01[f, g, h])$:

$$(4.10) \quad \kappa_0(f, g, h) = \frac{p^3}{C_q} \pi_{f, g, h}\text{AJ}^{k,\epsilon,m}_0(\Delta^{1,1,1; \delta}_1),$$

in which $\delta = 1$ is the trivial character of $(\mathbb{Z}/p\mathbb{Z})^\times$. Since $\mu^3$ induces a finite map of degree $(p - 1)^3$ from the support of $\pi_1(1,1,1; \delta)$ to $\pi_01$, it follows from the convention adopted in (3.7) that

$$\kappa_0(f, g, h) := \mu^3 \kappa_1(f, g, h) = \frac{p^3}{C_q} \pi_{f, g, h}\text{AJ}^{k,\epsilon,m}_0(\Delta^{0,0,0}_0),$$

where $\text{AJ}^{k,\epsilon,m}_0(\Delta^{0,0,0}_0)$ is defined to be the class realized by the same extension class as in (3.5), after replacing $X_1$ by the curve $X_01$ and replacing $\Delta$ by the cycle $\Delta^{0,0,0}_0$ arising from (4.4). Since $\Delta^{k,\epsilon,m}_0$ is fibered over $\Delta_0$, the same argument as in (4.9) then shows that

$$\text{AJ}^{k,\epsilon,m}_0(\Delta_0) = \text{AJ}^{(\epsilon_k, \epsilon_\ell, \epsilon_m)}(\Delta^{k,\epsilon,m}_0).$$

Since $\pi_{f, g, h}\text{AJ}^{k,\epsilon,m}_0(\Delta_0) = \frac{p}{C_q} \pi_{f, g, h}\text{AJ}^{k,\epsilon,m}_0(\Delta^{0,0,0}_0)$, the proposition follows.

**Theorem 4.1.** With notations as before, letting $c = r + 2$, we have

$$(\varpi_1, \varpi_1, \varpi_1), \kappa_1(f, g, h) = \frac{\mathcal{E}^{\text{bal}}(f, g, h)}{\mathcal{E}(f, g, h)\mathcal{E}(h, h)} \times \kappa(f, g, h),$$

where

$$\mathcal{E}^{\text{bal}}(f, g, h) = (1 - \alpha f \beta g \beta h p^{-c})(1 - \beta f \alpha g \beta h p^{-c})(1 - \beta f \beta g \alpha h p^{-c})(1 - \beta f \beta g \beta h p^{-c}),$$

and

$$\mathcal{E}(f, g, h) = 1 - \chi_f^{-1}(p)\beta^2 p^1 - k, \quad \mathcal{E}(g, h) = 1 - \chi_g^{-1}(p)\beta^2 p^1 - \ell, \quad \mathcal{E}(h, h) = 1 - \chi_h^{-1}(p)\beta^2 p^1 - m.$$
When combined with Lemma 4.4, Lemma 4.5 equips us with a completely explicit formula for comparing \((\pi_1, \pi_1, \pi_1)_{e^*(\Delta_{01}^f)}\) with the generalised diagonal cycle \(\Delta^f\). Namely, since the correspondences \([p], 1, 1\), \((1, [p], 1)\) and \((1, 1, [p])\) induce multiplication by \(p^k\), \(p^k\) and \(p^m\) respectively on the \((f, g, h)\)-isotypic parts, while \((T_p, 1, 1)\), \((1, T_p, 1)\), and \((1, 1, T_p)\) induce multiplication by \(a_p(f)\), \(a_p(g)\), and \(a_p(h)\) respectively, it follows that, with notations as in the proof of Lemma 4.5,

\[
\begin{align*}
\pi_{f,g,h}(D_1) &= a_p(f)\pi_{f,g,h}(\Delta^f), \\
\pi_{f,g,h}(D_2) &= a_p(g)\pi_{f,g,h}(\Delta^f), \\
\pi_{f,g,h}(D_3) &= a_p(h)\pi_{f,g,h}(\Delta^f),
\end{align*}
\]

and that

\[
\begin{align*}
\pi_{f,g,h}(E_1) &= (a_p^2(f) - (p + 1)p^k)\pi_{f,g,h}(\Delta^f), \\
\pi_{f,g,h}(E_2) &= (a_p^2(g) - (p + 1)p^k)\pi_{f,g,h}(\Delta^f), \\
\pi_{f,g,h}(E_3) &= (a_p^2(h) - (p + 1)p^m)\pi_{f,g,h}(\Delta^f).
\end{align*}
\]

By projecting the various formulae for \((\pi_1, \pi_1, \pi_1)_{e^*(\Delta_{01}^f)}\) that are given in Lemma 4.5 to the \((f, g, h)\)-isotypic component and substituting them into Lemma 4.4, one obtains an expression for \(e_{f,g,h}(\pi_1, \pi_1, \pi_1)_{e^*(\Delta_{01}^f)}\) as a multiple of \(\pi_{f,g,h}(\Delta^f)\) by an explicit factor, which is a rational function in \(\alpha_f\), \(\alpha_g\) and \(\alpha_h\). This explicit factor is somewhat tedious to calculate by hand, but the identity asserted in Theorem 4.1 is readily checked with the help of a symbolic algebra package. 

\[\square\]

5. Triple product \(p\)-adic \(L\)-functions and the reciprocity law

Let \((f, g, h)\) be a triple of \(p\)-adic Hida families of tame levels \(M_f, M_g, M_h\) and tame characters \(\chi_f, \chi_g, \chi_h\) as in the previous section. Let also \((f^*, g^*, h^*) = (f \otimes \chi_f, g \otimes \chi_g, h \otimes \chi_h)\) denote the conjugate triple. As before, we assume \(\chi_f\chi_g\chi_h = 1\) and set \(M = \text{lcm}(M_f, M_g, M_h)\).

Let \(\Lambda_f, \Lambda_g\) and \(\Lambda_h\) be the finite flat extensions of \(\Lambda\) generated by the coefficients of the Hida families \(f, g\) and \(h\), and set \(\Lambda_{fgh} = \Lambda_f \otimes \Lambda_g \otimes \Lambda_h\). Let also \(\mathcal{Q}_f\) denote the fraction field of \(\Lambda_f\) and define

\[\mathcal{Q}_{f,gh} := \mathcal{Q}_f \otimes \Lambda_g \otimes \Lambda_h.\]

Let \(\mathcal{W}_{fgh}^0 := \mathcal{W}_f^0 \times \mathcal{W}_g^0 \times \mathcal{W}_h^0 \subset \mathcal{W}_{fgh} = \text{Spf}(\Lambda_{fgh})\) denote the set of triples of crystalline classical points, at which the three Hida families specialize to modular forms with trivial nebentype at \(p\) (and may be either old or new at \(p\)). This set admits a natural partition, namely

\[\mathcal{W}_{fgh}^0 = \mathcal{W}_{fgh}^f \sqcup \mathcal{W}_{fgh}^g \sqcup \mathcal{W}_{fgh}^h \sqcup \mathcal{W}_{fgh}^{bal}\]

where

- \(\mathcal{W}_{fgh}^f\) denotes the set of points \((x, y, z) \in \mathcal{W}_{fgh}^0\) of weights \((k, \ell, m)\) such that \(k \geq \ell + m\).
- \(\mathcal{W}_{fgh}^g\) and \(\mathcal{W}_{fgh}^h\) are defined similarly, replacing the role of \(f\) with \(g\) (resp. \(h\)).
— $\mathcal{W}_{\text{fgh}}^{\text{bal}}$ is the set of balanced triples, consisting of points $(x, y, z)$ of weights $(k, \ell, m)$ such that each of the weights is strictly smaller than the sum of the other two.

Each of the four subsets appearing in the above partition is dense in $\mathcal{W}_{\text{fgh}}$ for the rigid-analytic topology.

Recall from (1.34) the spaces of $\Lambda$-adic test vectors $S^{\text{ord}}_{\Lambda}(M, \chi_f)[\mathfrak{f}]$. For any choice of a triple

$$(\tilde{f}, \tilde{g}, \tilde{h}) \in S^{\text{ord}}_{\Lambda}(M, \chi_f)[\mathfrak{f}] \times S^{\text{ord}}_{\Lambda}(M, \chi_g)[\mathfrak{g}] \times S^{\text{ord}}_{\Lambda}(M, \chi_h)[\mathfrak{h}]$$

of $\Lambda$-adic test vectors of tame level $M$, in [DR14, Lemma 2.19 and Definition 4.4] we constructed a $p$-adic $L$-function $\mathcal{L}_p(\tilde{f}, \tilde{g}, \tilde{h})$ in $\mathcal{Q}_p \otimes \Lambda_g \otimes \Lambda_h$, giving rise to a meromorphic rigid-analytic function

$$(5.1) \quad \mathcal{L}_p(\tilde{f}, \tilde{g}, \tilde{h}) : \mathcal{W}_{\text{fgh}} \rightarrow \mathbb{C}_p.$$  

As shown in [DR14, §4], this $p$-adic $L$-function is characterized by an interpolation property relating its values at classical points $(x, y, z) \in \mathcal{W}_{\text{fgh}}^{\text{fgh}}$ to the central critical value of Garrett’s triple-product complex $L$-function $L(f_x, g_y, h_z, s)$ associated to the triple of classical eigenforms $(f_x, g_y, h_z)$. The fudge factors appearing in the interpolation property depend heavily on the choice of test vectors: cf. [DR14, §4] and [DLR15, §2] for more details. In a recent preprint, Hsieh [H17] has found an explicit choice of test vectors, which yields a very optimal interpolation formula which shall be useful for our purposes. We describe it below:

**Proposition 5.1.** for every $(x, y, z) \in \mathcal{W}_{\text{fgh}}^{\text{fgh}}$ of weights $(k, \ell, m)$ we have

$$(5.2) \quad \mathcal{L}_p(\tilde{f}, \tilde{g}, \tilde{h})^\circ(x, y, z) = \frac{a(k, \ell, m)}{(f_x^0, f_y^0)^2} \cdot \epsilon^2(x, y, z) \cdot \prod_{v \mid N} C_v \times L(f_x^0, g_y^0, h_z^0, c)$$

where

i) $c = \frac{k+\ell+m-2}{2}$,

ii) $a(k, \ell, m) = (2\pi)^{-2k} \cdot (k+\ell+m-4)! \cdot (k+\ell-m-2)! \cdot (k-\ell-m-2)! \cdot (k-\ell+1)!$,

iii) $\epsilon(x, y, z) = \mathcal{E}(x, y, z)/\mathcal{E}_0(x)\mathcal{E}_1(x)$ with

$\mathcal{E}_0(x) := 1 - \chi_f^{-1}(p) \alpha_{f_x}^2 p^{1-k}$,

$\mathcal{E}_1(x) := 1 - \chi_f(p) \alpha_{f_x}^{-2} p^k$,

$\mathcal{E}(x, y, z) := \left(1 - \chi_f(p) \alpha_{f_x}^{-1} \alpha_{g_y} \alpha_{h_z} p^{\frac{k-\ell-m}{2}}\right) \times \left(1 - \chi_f(p) \alpha_{f_x}^{-1} \alpha_{g_y} \beta_{h_z} p^{\frac{k-\ell-m}{2}}\right)$

$\times \left(1 - \chi_f(p) \alpha_{f_x}^{-1} \beta_{g_y} \alpha_{h_z} p^{\frac{k-\ell-m}{2}}\right) \times \left(1 - \chi_f(p) \alpha_{f_x}^{-1} \beta_{g_y} \beta_{h_z} p^{\frac{k-\ell-m}{2}}\right)$.

iv) The local constant $C_v \in \mathcal{Q}(f_x, g_y, h_z)$ depends only on the admissible representations of $\mathbf{GL}_2(\mathbb{Q}_v)$ associated to $(f_x, g_y, h_z)$ and on the local components at $v$ of the test vectors.

Moreover, there exists a distinguished choice of test vectors $(\tilde{f}, \tilde{g}, \tilde{h})$ (as specified by Hsieh in [H17, §3]) for which $\mathcal{L}_p(\tilde{f}, \tilde{g}, \tilde{h})$ lies in $\Lambda_{\text{fgh}}$ and the local constants may be taken to be $C_v = 1$ at all $v \mid N\infty$. 

Démonstration. This follows from [H17, Theorem A], after spelling out explicitly the definitions involved in Hsieh’s formulation.

Let us remark that throughout the whole article [DR14], it was implicitly assumed that \( f_x, g_x \) and \( h_m \) are all old at \( p \), and note that the definition we have given here of the terms \( \mathcal{E}_0(x), \mathcal{E}_1(x) \) and \( \mathcal{E}(x, y, z) \) is exactly the same as in [DR14] in such cases, because \( \beta_{f_x} = \chi_f(p)\alpha_{f_x}^{-1}p^{k-1} \) when \( f_x \) is old at \( p \).

In contrast with loc.cit., in the above proposition we also allow any of the eigenforms \( f_x, g_x \) and \( h_m \) to be new at \( p \) (which can only occur when the weight is 2); in such case, recall the usual convention adopted in §1.2 to set \( \beta_{\phi} = 0 \) when \( p \) divides the primitive level of an eigenform \( \phi \). With these notations, the current formulation of \( \mathcal{E}(x, y, z), \mathcal{E}_0(x) \) and \( \mathcal{E}_1(x) \) is the correct one, as one can readily verify by rewriting the proof of [DR14, Lemma 4.10].

5.1. Perrin-Riou’s regulator. Recall the \( \Lambda \)-adic cyclotomic character \( \varepsilon_{\text{cycl}} \) and the unramified characters \( \Psi_f, \Psi_g, \Psi_h \) of \( G_{\mathbb{Q}_p} \) introduced in Theorem 1.1. As a piece of notation, let \( \varepsilon_f : G_{\mathbb{Q}_p} \rightarrow \Lambda_f^\times \) denote the composition of \( \varepsilon_{\text{cycl}} \) and the natural inclusion \( \Lambda_f^\times \subseteq \Lambda_f^\times \), and likewise for \( \varepsilon_g \) and \( \varepsilon_h \). Expressions like \( \Psi_f \Psi_g \Psi_h \) or \( \varepsilon_f \varepsilon_g \varepsilon_h \) are a short-hand notation for the \( \Lambda_f^\times \)-valued character of \( G_{\mathbb{Q}_p} \); given by the tensor product of the three characters.

Let \( \mathbb{V}_f, \mathbb{V}_g \) and \( \mathbb{V}_h \) be the Galois representations associated to \( f, g \) and \( h \) in Theorem 1.1.

The purpose of this section is describing in precise terms the close connection between the diagonal cycles constructed above and the three-variable triple-product \( p \)-adic \( L \)-function. In order to do that, let us introduce the \( \Lambda_{fg} \)-modules

\[
\mathbb{V}_{fg}^! := \mathbb{V}_f \otimes \mathbb{V}_g \otimes \mathbb{V}_h(-1)(\frac{1}{2}) = \mathbb{V}_f \otimes \mathbb{V}_g \otimes \mathbb{V}_h(\varepsilon_{\text{cycl}} \varepsilon_f \varepsilon_g \varepsilon_h)(\frac{1}{2}).
\]

and

\[
\mathbb{V}_{fg}^!(M) := \mathbb{V}_f(M) \otimes \mathbb{V}_g(M) \otimes \mathbb{V}_h(M)(-1)(\frac{1}{2}).
\]

The pairing defined in (2.17) yields an identification \( \mathbb{H}^{111}(X_\infty^*) = H^1_{\text{ét}}(\bar{X}_\infty, \mathbb{Z}_p)^{\otimes 3}(2)(\frac{1}{2}) \). As explained in (1.26), \( \mathbb{V}_{fg}^!(M) \) is isomorphic to the direct sum of several copies of \( \mathbb{V}_{fg}^! \), and there are canonical projections \( \varpi_f, \varpi_g, \varpi_h \) which assemble into a \( G_{\mathbb{Q}_p} \)-equivariant map

\[
\varpi_{f,g,h} : \mathbb{H}^{111}(X_\infty^*) = H^1_{\text{ét}}(\bar{X}_\infty, \mathbb{Z}_p)^{\otimes 3}(2)(\frac{1}{2}) \rightarrow \mathbb{V}_{fg}^!(M).
\]

Recall the three-variable \( \Lambda \)-adic global cohomology class

\[
\kappa_\infty(\epsilon_1 \omega^{-k_x}, \epsilon_2 \omega^{-k_y}, \epsilon_3 \omega^{-m_z}; 1) = \kappa_\infty(1, 1, 1; 1) \in H^1(\mathbb{Q}, \mathbb{H}^{111}(X_\infty^*))
\]

introduced in (4.1).

Set \( C_q(f, g, h) := (a_q(f) - q - 1)(a_q(g) - q - 1)(a_q(h) - q - 1) \). Note that \( C_q(f, g, h) \) is a unit in \( \Lambda_{fg} \), because its classical specializations are \( p \)-adic units (cf. (4.2)).

**Definition 5.2.** Define

\[
\kappa(f, g, h) := \frac{1}{C_q(f, g, h)} \cdot \varpi_{f,g,h}(\kappa_\infty(\epsilon_1 \omega^{-k_x}, \epsilon_2 \omega^{-k_y}, \epsilon_3 \omega^{-m_z}; 1)) \in H^1(\mathbb{Q}, \mathbb{V}_{fg}^!(M))
\]
to be the projection of the above class to the \((f, g, h)\)-isotypical component.

In the above definition, we normalize \(\kappa(f, g, h)\) by the constant \(C_f(f, g, h)\) so that the classical specializations of \(\kappa(f, g, h)\) at classical points coincide with the classes \(\kappa_1(f_\alpha, g_\alpha, h_\alpha)\) introduced in (4.2).

Let
\[
\text{res}_p : H^1(\mathbb{Q}, V^\dagger_{fgh}(M)) \to H^1(\mathbb{Q}_p, V^\dagger_{fgh}(M))
\]
denote the restriction map to the local cohomology at \(p\) and set
\[
\kappa_p(f, g, h) := \text{res}_p(\kappa(f, g, h)) \in H^1(\mathbb{Q}_p, V^\dagger_{fgh}(M)).
\]

The main result of this section asserts that the \(p\)-adic \(L\)-function \(\mathcal{L}_p^G(\tilde{f}, \tilde{g}, \tilde{h})\) introduced in §5 can be recast as the image of the \(\Lambda\)-adic class \(\kappa_p(f, g, h)\) under a suitable three-variable Perrin-Riou regulator map whose formulation relies on a choice of families of periods which depends on the test vectors \(\tilde{f}, \tilde{g}, \tilde{h}\).

The recipe we are about to describe depends solely on the projection of \(\kappa_p(f, g, h)\) to a suitable sub-quotient of \(V^\dagger_{fgh}\) which is free of rank one over \(\Lambda_{fgh}\), and whose definition requires the following lemma.

**Lemma 5.3.** The Galois representation \(V^\dagger_{fgh}\) is endowed with a four-step filtration
\[
0 \subset V^+_{fgh} \subset V^0_{fgh} \subset V^-_{fgh} \subset V^\dagger_{fgh}
\]
by \(G_{Q_p}\)-stable \(\Lambda_{fgh}\)-submodules of ranks 0, 1, 4, 7 and 8 respectively.

The group \(G_{Q_p}\) acts on the successive quotients for this filtration (which are free over \(\Lambda_{fgh}\) of ranks 1, 3, 3 and 1 respectively) as a direct sum of one dimensional characters,
\[
\begin{align*}
V^+_{fgh} &= \eta^+_{fgh}, & V^0_{fgh} &= \eta^0_{fgh} \\
V^-_{fgh} &= \eta^-_{fgh} \\
V^\dagger_{fgh} &= \eta^\dagger_{fgh}
\end{align*}
\]
where
\[
\begin{align*}
\eta^+_{fgh} &= (\Psi_f \Psi_g \Psi_h \times \varepsilon_{\text{cyc}}(\mathbf{f} \mathbf{g} \mathbf{h}))^{1/2}, & \eta^0_{fgh} &= \Psi_f \Psi_g \Psi_h \times \varepsilon_{\text{cyc}}(\mathbf{f} \mathbf{g} \mathbf{h})^{-1/2}, \\
\eta^-_{fgh} &= \chi_f^{-1} \Psi_f \Psi_g^{-1} \Psi_h^{-1} \times \varepsilon_{\text{cyc}}(\mathbf{f} \mathbf{g} \mathbf{h})^{1/2}, & \eta^\dagger_{fgh} &= \chi_f^{-1} \Psi_f \Psi_g \Psi_h \times (\varepsilon_{\text{cyc}}(\mathbf{f} \mathbf{g} \mathbf{h})^{-1/2}, \\
\eta^h_{g} &= \chi_g^{-1} \Psi_f \Psi_g^{-1} \Psi_h^{-1} \times \varepsilon_{\text{cyc}}(\mathbf{f} \mathbf{g} \mathbf{h})^{1/2}, & \eta^g_{h} &= \chi_g \Psi_f \Psi_g \Psi_h^{-1} \times (\varepsilon_{\text{cyc}}(\mathbf{f} \mathbf{g} \mathbf{h})^{1/2), \\
\eta^h_{f} &= \chi_h^{-1} \Psi_f^{-1} \Psi_g^{-1} \Psi_h^{-1} \times \varepsilon_{\text{cyc}}(\mathbf{f} \mathbf{g} \mathbf{h})^{1/2}, & \eta^f_{g} &= \chi_h \Psi_f^{-1} \Psi_g \Psi_h^{-1} \times (\varepsilon_{\text{cyc}}(\mathbf{f} \mathbf{g} \mathbf{h})^{-1/2}. 
\end{align*}
\]

**Démonstration.** Let \(\phi\) be a Hida family of tame character \(\chi\) as in §1.3. Let \(\psi_\phi\) denote the unramified character of \(G_{Q_p}\) sending a Frobenius element \(F_{Q_p}\) to \(a_p(\phi)\) and recall from (1.12) that the restriction of \(V_\phi\) to \(G_{Q_p}\) admits a filtration
\[
0 \to V_\phi^+ \to V_\phi \to V_\phi^- \to 0
\]
with
\[
V_\phi^+ \simeq \Lambda_\phi(\psi_\phi^{-1} \varepsilon_{\text{cyc}}(\mathbf{f} \mathbf{g} \mathbf{h})), & V_\phi^- \simeq \Lambda_\phi(\psi_\phi).
\]
Set
\[ V_{fgh}^{++} = V_f^+ \otimes V_g^+ \otimes V_h^+ (\varepsilon_{cyc}^{-1/2}, \varepsilon_g^{-1/2}, \varepsilon_h^{-1/2}), \]
\[ V_{fgh}^+ = (V_f \otimes V_g^+ \otimes V_h^+ + V_f^+ \otimes V_g \otimes V_h^+ + V_f^+ \otimes V_g^+ \otimes V_h)(\varepsilon_{cyc}^{-1/2}, \varepsilon_g^{-1/2}, \varepsilon_h^{-1/2}). \]
\[ V_{fgh}^- = (V_f \otimes V_g \otimes V_h^+ + V_f \otimes V_g^+ \otimes V_h + V_f^+ \otimes V_g \otimes V_h^+)(\varepsilon_{cyc}^{-1/2}, \varepsilon_g^{-1/2}, \varepsilon_h^{-1/2}). \]

It follows from the definitions that these three representations are \( A_{fgh}[G_{Q_p}] \)-submodules of \( V_{fgh}^\dagger \) of ranks 1, 4, 7 as claimed. Moreover, since \( \chi_f \chi_g \chi_h = 1 \), the rest of the lemma follows from (1.12).

A one-dimensional character \( \eta : G_{Q_p} \rightarrow \mathbb{C}_p^\times \) is said to be of Hodge-Tate weight \(-j\) if it is equal to a finite order character times the \( j\)-th power of the cyclotomic character. The following is an immediate corollary of Lemma 5.3.

**Corollary 5.4.** Let \((x, y, z) \in W_{fgh}^\circ\) be a triple of classical points of weights \((k, \ell, m)\). The Galois representation \( V_{f, g, h}^\dagger \) is endowed with a four-step \( G_{Q_p}\)-stable filtration

\[ 0 \subset V_{f, g, h}^{++} \subset V_{f, g, h}^\dagger \subset V_{f, g, h}^\bullet \subset V_{f, g, h}^\dagger, \]

and the Hodge-Tate weights of its successive quotients are:

| Subquotient | Hodge-Tate weights |
|-------------|--------------------|
| \( V_{f, g, h}^{++} \) | \(-k-\ell-m+1\) |
| \( V_{f, g, h}^\dagger / V_{f, g, h}^{++} \) | \(-k-\ell-m, -k+m, -k+\ell+m\) |
| \( V_{f, g, h}^\bullet / V_{f, g, h}^\dagger \) | \(-k+m, -k-\ell-m-1, k+\ell-m+1\) |
| \( V_{f, g, h} / V_{f, g, h}^\dagger \) | \(-k+m+2\) |

**Corollary 5.5.** The Hodge-Tate weights of \( V_{f, g, h}^\dagger \) are all strictly negative if and only if \((k, \ell, m)\) is balanced.

Let \( \psi_{f}^{g,h} \) and \( \psi_{f}^{g,h}(M) \) be the subquotient of \( V_{fgh}^\dagger \) (resp. of \( V_{fgh}^\dagger(M) \)) on which \( G_{Q_p} \) acts via (several copies of) the character

\[ \eta_{f}^{g,h} := \psi_{f}^{g,h} \times \Theta_{f}^{g,h} \]

where

- \( \psi_{f}^{g,h} \) is the unramified character of \( G_{Q_p} \) sending \( F_r \) to \( \chi_f^{-1}(p) a_y(f) a_p(g)^{-1} a_p(h)^{-1} \), and

- \( \Theta_{f}^{g,h} \) is the \( A_{fgh}\)-adic cyclotomic character whose specialization at a point of weight \((k, \ell, m)\) is \( \varepsilon_{cyc}^t \) with \( t := (-k + \ell + m)/2 \).

The classical specializations of \( V_{f}^{g,h} \) are

\[ V_{f, g, h}^{g,h} := V_{f, g, h} \otimes V_{g}^+ \otimes V_{h}^+ (\varepsilon_{cyc}^{-1/2}, \varepsilon_g^{-1/2}, \varepsilon_h^{-1/2}) \sim L_p(\chi_f^{-1} \psi_{f} a_y^{-1} \psi_{h}^{-1}, t), \]

where the coefficient field is \( L_p = Q_p(f, g, h) \). Note that \( t > 0 \) when \((x, y, z) \in W_{fgh}^\text{hal} \) while \( t \leq 0 \) when \((x, y, z) \in W_{fgh}^\text{hal} \).
Recall now from §1.4 the Dieudonné module \(D(V_{f_{x}}^{g_{x}h_{z}}(Mp))\) associated to \((5.6)\). As it follows from loc. cit., every triple
\[
(\eta_{1}, \omega_{2}, \omega_{3}) \in D(V_{f_{x}}^{+}(Mp)) \times D(V_{g_{x}h_{z}}^{-}(Mp)) \times D(V_{h_{z}}^{-}(Mp))
\]
gives rise to a linear functional \(\eta_{1} \otimes \omega_{2} \otimes \omega_{3} : D(V_{f_{x}}^{g_{x}h_{z}}(Mp)) \rightarrow L_{p}\).

In order to deal with the \(p\)-adic variation of these Dieudonné modules, write \(\mathcal{V}_{f_{x}}^{g_{x}h_{z}}(M)\) as
\[
\mathcal{V}_{f_{x}}^{g_{x}h_{z}}(M) = U(\mathcal{Q}_{f_{x}}^{g_{x}h_{z}})
\]
where \(U\) is the unramified \(\Lambda_{f_{x}g_{x}h_{z}}\)-adic representation of \(G_{Q_{p}}\) given by (several copies of) the character \(\psi_{f_{x}}^{g_{x}h_{z}}\).

As in §1.4, define the \(\Lambda\)-adic Dieudonné module
\[
\mathbb{D}(U) := (U \hat{\otimes} \mathbb{Z}_{p}^{nr})^{G_{Q_{p}}}.
\]

In view of (1.29), for every \((x, y, z) \in \mathcal{V}_{f_{x}}^{g_{x}h_{z}}\) there is a natural specialisation map
\[
\nu_{x,y,z} : \mathbb{D}(U) \rightarrow D(U_{f_{x}}^{g_{x}h_{z}})
\]
where \(U_{f_{x}}^{g_{x}h_{z}} := U \otimes_{\Lambda_{f_{x}g_{x}h_{z}}} Q_{p}(f_{x}, g_{y}, h_{z}) \cong V_{f_{x}}^{g_{x}h_{z}}(Mp)(-t)\).

**Proposition 5.6.** For any triple of test vectors
\[
(f_{x}, g_{y}, h_{z}) \in S_{\Lambda}^{ord}(M, \chi_{f})[f] \times S_{\Lambda}^{ord}(M, \chi_{g})[g] \times S_{\Lambda}^{ord}(M, \chi_{h})[h],
\]
there exists a homomorphism of \(\Lambda_{f_{x}g_{x}h_{z}}\)-modules
\[
\langle \ , \nu_{f_{x}}^{g_{y}} \otimes \omega_{g_{y}}^{*} \otimes \omega_{h_{z}}^{*} \rangle : \mathbb{D}(U) \rightarrow \mathcal{Q}_{f_{x}g_{y}h_{z}}
\]
such that for all \(\lambda \in \mathbb{D}(U)\) and all \((x, y, z) \in \mathcal{V}_{f_{x}}^{g_{x}h_{z}}\) such that \(f_{x}\) is the ordinary stabilization of an eigenform \(f_{x}^{*}\) of level \(M\) :
\[
\nu_{x,y,z}(\lambda, \eta_{f_{x}}^{g_{y}} \otimes \omega_{g_{y}}^{*} \otimes \omega_{h_{z}}^{*}) = \frac{1}{E_{0}(f_{x}^{*})E_{1}(f_{x}^{*})} \times (\nu_{x,y,z}(\lambda), \eta_{f_{x}}^{g_{y}} \otimes \omega_{g_{y}}^{*} \otimes \omega_{h_{z}}^{*}).
\]

Recall from (1.31) that
\[
E_{0}(f_{x}^{*}) = 1 - \chi^{-1}(p)\beta_{f_{x}}^{2}P^{-1-k}, \quad E_{1}(f_{x}^{*}) = 1 - \chi(p)\alpha_{f_{x}}^{-2}P^{k-2}.
\]

**Démonstration.** Since \(U\) is isomorphic to the unramified twist of \(V_{f}^{-} \otimes V_{g}^{+} \otimes V_{h_{z}}^{+}\), this follows from Proposition 1.5 because \(E_{0}(f_{x}^{*}) = E_{0}(f_{x}^{*})\) and \(E_{1}(f_{x}^{*}) = E_{1}(f_{x}^{*})\).

It follows from Example 1.4 (a) and (b) that the Bloch-Kato logarithm and dual exponential maps yield isomorphisms
\[
\text{log}_{BK} : H^{1}(Q_{p}, V_{f_{x}}^{g_{x}h_{z}}) \overset{\sim}{\rightarrow} D(V_{f_{x}}^{g_{x}h_{z}}), \quad \text{if } t > 0,
\]
\[
\text{exp}_{BK} : H^{1}(Q_{p}, V_{f_{x}}^{g_{x}h_{z}}) \overset{\sim}{\rightarrow} D(V_{f_{x}}^{g_{x}h_{z}}), \quad \text{if } t \leq 0.
\]

Define
\[
(5.7) \quad \mathcal{E}^{PR}(x, y, z) = \frac{1 - p^{-\frac{k-c}{2}-1}}{1 - p^{-\frac{k-c}{2}}} \quad \frac{\alpha_{f_{x}}^{-1} \alpha_{g_{y}} \alpha_{h_{z}}}{\alpha_{f_{x}} \alpha_{g_{y}} \alpha_{h_{z}}} = \frac{1 - p^{-c} \beta_{f_{x}} \alpha_{g_{y}} \alpha_{h_{z}}}{1 - p^{-c} \alpha_{f_{x}} \beta_{g_{y}} \beta_{h_{z}}}
\]

The following is a three-variable version of Perrin-Riou’s regulator map constructed in [PR95] and [LZ14].
Proposition 5.7. There is a homomorphism
\[ \mathcal{L}_{f,gh} : H^1(Q_p, \mathbb{V}^+_{f,gh}(M)) \rightarrow \mathbb{D}(\mathbb{U}) \]
such that for all \( \kappa_p \in H^1(Q_p, \mathbb{V}^+_{f,gh}(M)) \) the image \( \mathcal{L}_{f,gh}(\kappa_p) \) satisfies the following interpolation properties:

(i) For all balanced points \((x, y, z) \in \mathcal{W}^\text{bal}_{fgh}\),
\[ \nu_{x,y,z}(\mathcal{L}_{f,gh}(\kappa_p)) = \frac{(-1)^t}{t!} \cdot \mathcal{E}^\text{PR}(x, y, z) \cdot \log_{BK}(\nu_{x,y,z}(\kappa_p)), \]

(ii) For all points \((x, y, z) \in \mathcal{W}^I_{fgh}\),
\[ \nu_{x,y,z}(\mathcal{L}_{f,gh}(\kappa_p)) = (-1)^t \cdot (1 - t)! \cdot \mathcal{E}^\text{PR}(x, y, z) \cdot \exp_{BK}^*(\nu_{x,y,z}(\kappa_p)). \]

Démonstration. This follows by standard methods as in [KLZ17, Theorem 8.2.8], [LZ14, Appendix B], [DR17, §5.1].

Proposition 5.8. The class \( \kappa_p(f, g, h) \) belongs to the image of \( H^1(Q_p, \mathbb{V}^+_{fgh}(M)) \) in \( H^1(Q_p, \mathbb{V}^+_{fgh}(M)) \) under the map induced from the inclusion \( \mathbb{V}^+_{fgh}(M) \hookrightarrow \mathbb{V}^+_{fgh}(M) \).

Démonstration. Let \((x, y, z) \in \mathcal{W}^p_{fgh}\) be a triple of classical points of weights \((k, \ell, m)\). By the results proved in §4, the cohomology class \( \kappa_p(f_x, g_y, h_z) \) is proportional to the image under the \( p \)-adic étale Abel-Jacobi map of the cycles appearing in (4.8), that were introduced in [DR14, §3]. The purity conjecture for the monodromy filtration is known to hold for the variety \( \mathcal{A}^k \times \mathcal{A}^\ell \times \mathcal{A}^m \) by the work of Saito (cf. [S97], [N98, (3.2)]). By Theorem 3.1 of loc. cit., it follows that the extension \( \kappa_p(f_x, g_y, h_z) \) is crystalline. Hence \( \kappa_p(f_x, g_y, h_z) \) belongs to \( H^1_I(Q_p, V^+_{f_x, g_y, h_z}(M)) \subset H^1(Q_p, V^+_{f_x, g_y, h_z}(M)). \)

Since \((k, \ell, m)\) is balanced, Corollary 5.5 implies that \( V^+_{f_x, g_y, h_z} \) is the sub-representation of \( V^+_{f_x, g_y, h_z} \) on which the Hodge-Tate weights are all strictly negative. As is well-known (cf. [F90, Lemma 2, p. 125], [LZ19, §3.3] for similar results), the finite Bloch-Kato local Selmer group of an ordinary representation can be recast à la Greenberg [G89] as
\[ H^1_I(Q_p, V^+_{f_x, g_y, h_z}) = \ker \left( H^1(Q_p, V^+_{f_x, g_y, h_z}) \rightarrow H^1(I_p, V^+_{f_x, g_y, h_z}/V^+_{f_x, g_y, h_z}) \right), \]
where \( I_p \) denotes the inertia group at \( p \).

Since the set of balanced classical points is dense in \( \mathcal{W}_{fgh} \) for the rigid-analytic topology, it follows that the \( \Lambda \)-adic class \( \kappa_p(f, g, h) \) belongs to the kernel of the natural map
\[ H^1(Q_p, \mathbb{V}^+_{fgh}(M)) \rightarrow H^1(I_p, \mathbb{V}^+_{fgh}(M)/\mathbb{V}^+_{fgh}(M)). \]
Since the kernel of the restriction map
\[ H^1(Q_p, \mathbb{V}^+_{fgh}(M)/\mathbb{V}^+_{fgh}(M)) \rightarrow H^1(I_p, \mathbb{V}^+_{fgh}(M)/\mathbb{V}^+_{fgh}(M)) \]
is trivial by Lemma 5.3, the result follows.

\( \square \)
Thanks to Lemma 5.3 and Proposition 5.8, we are entitled to define
\begin{equation}
\kappa_p^f(f, g, h)^- \in H^1(Q_p, \mathbb{V}_f^gh(M))
\end{equation}
as the projection of the local class $\kappa_p(f, g, h)$ to $\mathbb{V}_f^gh(M)$.

**Theorem 5.1.** For any triple of $\Lambda$-adic test vectors $(\tilde{f}, \tilde{g}, \tilde{h})$, the following equality holds in the ring $\mathcal{Q}_{f, gh}$:
\[\langle \mathcal{L}_{f, gh}(\kappa_p^f(f, g, h)^-), \eta_f \otimes \omega_{g^*} \otimes \omega_{h^*} \rangle = \mathcal{L}_f^f(\tilde{f}, \tilde{g}, \tilde{h}).\]

**Démonstration.** It is enough to prove this equality for a subset of classical points that is dense for the rigid-analytic topology, and we shall do so for all balanced triple of crystalline classical points $(x, y, z) \in \mathbb{W}_f^{bal}$ such that $f_x$, $g_z$ and $h_m$ are respectively the ordinary stabilization of an eigenform $f := f_x$, $g := g^*_z$ and $h := h^*_m$ of level $M$.

Set $\kappa_p^- := \kappa_p^f(f, g, h)^-$ and $\mathcal{L} = \langle \mathcal{L}_{f, gh}(\kappa_p^-), \eta_f \otimes \omega_{g^*} \otimes \omega_{h^*} \rangle$ for notational simplicity. Proposition 5.6 asserts that the following identity holds in $L_p$:
\[\nu_{x,y,z}(\mathcal{L}) = \langle \nu_{x,y,z}(\mathcal{L}_{f, gh}(\kappa_p^-)), \eta_f \otimes \omega_{g^*} \otimes \omega_{h^*} \rangle.\]

Recall also from Proposition 1.5 that
\[\eta_f^x = \frac{1}{\mathcal{E}_1(f)} e_{\mathcal{E}_1}^x(\eta_f), \quad \omega_{g^*} = \mathcal{E}_0(g) e_{\mathcal{E}_2}^x(\omega_{g^*}), \quad \omega_{h^*} = \mathcal{E}_0(h) e_{\mathcal{E}_1}^y(\omega_{h^*})\]

and
\[\nu_{x,y,z}(\mathcal{L}_{f, gh}(\kappa_p^-)) = \frac{(-1)^t}{t!} \cdot \mathcal{E}_{PR}(x, y, z) \log_{BK}(\nu_{x,y,z}(\kappa_p^-))\]

by Proposition 5.7.

Recall the class $\kappa(f, g, h) = \kappa(f_x, g^*_z, h^*_m)$ introduced in (4.8) arising from the generalized diagonal cycles of [DR14]. As in (5.8), we may define $\kappa_p^f(f, g, h)^- \in H^1(Q_p, \mathbb{V}_f^gh(M))$ as the projection to $V_f^gh(M)$ of the restriction at $p$ of the global class $\kappa(f, g, h)$.

It follows from Theorem 4.1 that
\[(\mathcal{E}_1, \mathcal{E}_1, \mathcal{E}_1)_{\nu_{x,y,z}(\kappa_p^-)} = \frac{\mathcal{E}_{PR}(x, y, z)}{(1 - \beta_f/\alpha_f)(1 - \beta_g/\alpha_g)(1 - \beta_h/\alpha_h)} \times \kappa_p^f(f, g, h)^-\]

where
\[\mathcal{E}_{PR}(x, y, z) = (1 - \alpha_f \beta_g \beta_h p^-c)(1 - \beta_f \alpha_g \beta_h p^-c)(1 - \beta_f \beta_g \alpha_h p^-c)(1 - \beta_f \beta_g \beta_h p^-c).\]

The combination of the above identities shows that the value of $\mathcal{L}$ at the balanced triple $(x, y, z)$ is
\[\nu_{x,y,z}(\mathcal{L}) = \frac{(-1)^t \cdot \mathcal{E}_{PR}(x, y, z) \mathcal{E}_{f, gh}(x, y, z)}{t! \cdot \mathcal{E}_0(f) \mathcal{E}_1(f)} \times (\log_{BK}(\kappa_p^f(f, g, h)^-), \eta_f \otimes \omega_{g^*} \otimes \omega_{h^*}).\]

Besides, since the syntomic Abel-Jacobi map appearing in [DR14] is the composition of the étale Abel-Jacobi map and the Bloch-Kato logarithm, the main theorem of loc. cit. asserts in the present notations that
\[\nu_{x,y,z}(\mathcal{L}_f^f(\tilde{f}, \tilde{g}, \tilde{h})) = \frac{(-1)^t}{t!} \cdot \frac{\mathcal{E}_f(x, y, z)}{\mathcal{E}_0(f) \mathcal{E}_1(f)} \times (\log_{BK}(\kappa_p^f(f, g, h)^-), \eta_f \otimes \omega_{g^*} \otimes \omega_{h^*})\]

where
\[\mathcal{E}_f(x, y, z) = (1 - \beta_f \alpha_g \alpha_h p^-c)(1 - \beta_f \alpha_g \beta_h p^-c)(1 - \beta_f \beta_g \alpha_h p^-c)(1 - \beta_f \beta_g \beta_h p^-c).\]
Since 
\[ E_f(x, y, z) = E_{bal}(x, y, z) \times E_{PR}(x, y, z) \]
and the sign and factorial terms also cancel, we have
\[ \nu_{x,y,z}(L) = \nu_{x,y,z}(L_{pf}(\tilde{f}, \tilde{g}, \tilde{h})) , \]
as we wanted to show. The theorem follows. □
