July 18, 2009

Abstract

Recently, a chaotic cryptographic scheme based on composition maps was proposed. This paper studies the security of the scheme and reports the following findings: 1) the scheme can be broken by a differential attack with \(6 + \lceil \log_L(MN) \rceil\) chosen-plaintext, where \(MN\) is the size of plaintext and \(L\) is the number of different elements in plaintext; 2) the scheme is not sensitive to the changes of plaintext; 3) the two composition maps do not work well as a secure and efficient random number source.

1 Introduction

The development of information technology makes the transmission of digital data is carried out more and more frequently over all kinds of channels. Meanwhile, the security of digital data become more and more important. So, the demand of secure and fast encryption schemes become urgent. Due to the subtle similarities between cryptography and chaos, a great number of chaotic encryption schemes have been proposed in the past decade \cite{1, 2, 3, 4, 5, 6}. However, most of them have been found to be insecure in different extents from the view point of modern cryptography \cite{7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17}. As for how to evaluate the security of a chaotic cryptographic scheme, please refer to \cite{18}.

In general, the usage of chaos in designing encryption scheme can be classified as three categories: 1) generating pseudo-random number sequence, which is then used to determine position permutation; 2) generating pseudo-random bit sequence, which is then used to determine combination and/or composition of some basic encryption operations; 3) generating ciphertext directly when the data of plaintext is assigned as the initial condition or control parameter of a chaotic map. In \cite{19, 20, 21}, the possible application of composition of polynomial chaotic maps in designing encryption scheme was discussed. In this case, two composite polynomial chaotic maps are used to determine the position permutation and composition of basic encryption operations respectively. Since the schemes proposed in \cite{19, 20} are preliminary version of the one proposed in \cite{21}, this paper only focuses on the security of the latter. With our study, the following security problems are found: 1) the scheme can be broken with a differential attack; 2) the scheme is not sensitive with respect to the changes of plaintext; 3) the randomness of the pseudo-random number sequences generated by the two composition maps is weak.

The rest of this paper is organized as follows. Section \textsuperscript{2} describes the chaotic cryptographic scheme briefly. A comprehensive cryptanalysis on the scheme is presented in Sec. \textsuperscript{3}. The last section concludes this paper.
2 The Encryption Scheme Under Study

In [21], the structure of plaintext is not specified precisely. Without loss of generality, the plaintext here is denoted by a 2-D byte array of size $M \times N$ (height×width), $I = \{I(i,j)\}_{1 \leq i \leq M, 1 \leq j \leq N}$ and the corresponding ciphertext by $I' = \{I'(i,j)\}_{1 \leq i \leq M, 1 \leq j \leq N}$. The plaintext is considered as a 1D signal $\{I(k)\}_{k=1}^{MN}$ by scanning it in a raster order. Then, the chaotic cryptographic scheme can be described as follows\footnote{To make the presentation more concise and complete, some notations in the original paper are modified, and some details about the scheme are supplied and/or corrected also.}.

- **Secret key**: three sets of initial condition and control parameter of Eq. (1), $(x_0, \alpha_1, \alpha_2)$, $(x'_0, \alpha'_1, \alpha'_2)$, one set of initial condition and control parameter of Eq. (2), $(y_0, \alpha_3, \alpha_4)$, and a secret number $S \in \{0, \cdots, 255\}$.

\[
f(x) = \frac{1}{\alpha_2^2} \tan^2 \left( 5 \arctan \left( \frac{\tan(3 \arctan(\sqrt{x}))}{\alpha_1} \right) \right).
\]

\[
g(y) = \frac{1}{\alpha_4^2} \cot^2 \left( 8 \arctan \left( \alpha_3 \tan \left( 4 \arctan \left( \frac{1}{\sqrt{y}} \right) \right) \right) \right).
\]

- **Initialization**:
  - Iterate the map Eq. (1) $MN$ times to obtain three states sequences, $\{\psi_1(k)\}_{k=1}^{MN}$, $\{\psi_2(k)\}_{k=1}^{MN}$, $\{\psi_4(k)\}_{k=1}^{MN}$, under the three sets of initial condition and control parameter, $(x_0, \alpha_1, \alpha_2)$, $(x'_0, \alpha'_1, \alpha'_2)$, $(x_0, \alpha_1^*, \alpha_2^*)$, respectively;
  - Iterate the map Eq. (2) $MN$ times to obtain a states sequence $\{\psi_3(k)\}_{k=1}^{MN}$ under initial condition and control parameter $(y_0, \alpha_3, \alpha_4)$;
  - Generate four pseudo-random number sequences, $\{\phi_1(k)\}_{k=1}^{MN}$, $\{\phi_2(k)\}_{k=1}^{MN}$, $\{\phi_3(k)\}_{k=1}^{MN}$, $\{\phi_4(k)\}_{k=1}^{MN}$, as follows: $\phi_1(k) = [\psi_1(k) \cdot 10^{14}] \mod M$, $\phi_2(k) = [\psi_2(k) \cdot 10^{14}] \mod N$, $\phi_3(k) = [\psi_3(k) \cdot 10^{14}] \mod 256$, and $\phi_4(k) = [\psi_4(k) \cdot 10^{14}] \mod 256$.

- **Encryption**:
  - **Permutation**: for $k = 1 \sim MN$, swap the positions of two bytes $I(k)$ and $I(\phi_1(k) \cdot N + \phi_2(k))$. Denote the permuted plaintext with $I^* = \{I^*(i,j)\}_{1 \leq i \leq M, 1 \leq j \leq N}$.
  - **Confusion I**: for $k = 1 \sim MN$,

\[
I^*(k) = \psi_3(k) \oplus (I^*(k-1) \oplus \phi_3(k) \oplus I^*(k-1)), \tag{3}
\]

where $I^*(0) = S$, and $x + y = (x + y) \mod 256$.
  - **Confusion II**: for $k = 1 \sim MN$,

\[
I'(k) = I^*(k) \oplus \phi_4(k). \tag{4}
\]

- **Decryption**: The decryption approach is similar to the encryption one except that the main three encryption steps and the swap operations in the permutation step are carried out in a reverse order, and Eq. (3) is replaced by the following function.

\[
I^*(k) = ((I^*(k) \oplus I^*(k-1) \oplus \phi_3(k)) \oplus \phi_3(k) + 256) \mod 256. \tag{5}
\]
3 Cryptanalysis

3.1 Differential Attack

Differential attack is an attack to recover the information about secret key and/or plaintext by analyzing the evolution of differences when some pairs of plaintexts are encrypted with the same secret key. In [21, Sec. 5.4], the authors claimed the encryption scheme under study can withstand differential attack effectively. However, we find that the scheme can be broken by this attack easily with the following steps.

- Breaking Confusion I:

If two plaintexts, \( I_1 = \{I_1(k)\}_{k=1}^{MN} \) and \( I_2 = \{I_2(k)\}_{k=1}^{MN} \), are encrypted by the same secret key, one has the following equality.

\[
I_1'(k) \oplus I_2'(k) = I_1'(k) \oplus \phi_4(k) \oplus I_2'(k) \oplus \phi_4(k) = I_1'(k) \oplus I_2'(k) = \phi_3(k) \oplus (I_1'(k) \oplus \phi_3(k)) \oplus I_2'(k) (k-1) \oplus \phi_3(k) \oplus (I_2'(k) + \phi_3(k)) \oplus I_1'(k) (k-1) \oplus I_2'(k) (k-1) = (I_1'(k) + \phi_3(k)) \oplus (I_2'(k) + \phi_3(k)) \oplus (I_1'(k) (k-1) \oplus I_2'(k) (k-1))
\]

Furthermore, if the plaintexts, \( I_1 \) and \( I_2 \), are chosen of fixed value, one has

\[
(I_1'(k) \oplus I_2'(k)) \oplus (I_1'(k-1) \oplus I_2'(k-1)) = (I_1'(k) + \phi_3(k)) \oplus (I_2'(k) + \phi_3(k))
\]

Since the left part of the above equation, \( I_1(k) \) and \( I_2(k) \) are known, Eq. (8) can be simplified as the following equation.

\[ y = (a + x) \oplus (b + x), \]

where \( a, b, x \in \{0, 1, \cdots 255\} \).

It has been verified by computer that a set \( \{x, x \oplus 128\} \) can be determined uniquely with three different sets of \( (a, b) \), e.g. \( (9, 127), (1, 52), (33, 65) \). From Fact 1 one can see that \( \phi_3(k) \) and \( \phi_3(k) \oplus 128 \) are equivalent with respect to the encryption.

**Fact 1** \( \forall a, b \in \mathbb{Z}, (a \oplus 128) \oplus b = (a \oplus b) \oplus 128. \)

- Breaking Confusion II:

After \( \{\phi_3(k)\}_{k=1}^{MN} \) has been broken, only the step Confusion II is left for a plaintext of fixed value, \( I_1, I_1' \) can be determined. Then, one has

\[ \phi_4(k) = I_1'(k) \oplus I_1'(k), \]

for \( k = 1 \sim MN. \)

- Breaking Permutation:

After the steps Confusion I and Confusion II have been broken, only the step permutation is left. As shown in [22], any permutation-only cryptographic scheme can be broken with only \( O(\log_2(MN)) \) known/chosen plain-texts, where \( L \) is the number of different element in plain-text.
To validate performance of the proposed attack, some experiments on some plain-images of size 512 \times 512 have been performed. Besides $S = 33$, the same secret key used in [21, Sec. 3] was adopted: $(x_0, \alpha_1, \alpha_2) = (25.687, 2.10155, 3.569221), (x_0', \alpha_1', \alpha_2') = (574.461, 1.8874, 4.23562), (x_0^*, \alpha_1^*, \alpha_2^*) = (814.217217, 2.8912, 3.89954), (y_0, \alpha_3, \alpha_4) = (79.82, 61.522, 257.26223)$. The step *Confusion I* can be
broken with the six chosen plain-images of fixed values, 9, 127, 1, 52, 33 and 65, as shown in Fig. 1 and the corresponding cipher-images shown in Fig. 2. Then, the plain-image shown in Fig. 1a) and the corresponding cipher-images can break the step \textit{Confusion II}. Finally, the step \textit{Permutation} can be broken with \(\lceil\log_{256}(512 \cdot 512)\rceil = 3\) special plain-images shown in Fig. 3. The obtained equivalent secret key was used to decrypt another cipher-image, as shown in Fig. 4a), and the result is shown in Fig. 4b).

### 3.2 Some Other Security Defects

- Problems about Secret Key;
As specified in [18, Rule 5], the key space of a secure encryption scheme should be precisely specified and avoid non-chaotic regions. However, even with the measure used in [21], a great number of secret key should be excluded from the key space of the encryption scheme under study (see Fig. 5).

Figure 5: The parameters of $f(x)$ corresponding to positive Lyapunov exponent.

- Insufficient Randomness of Pseudo-Random Number Sequences $\{\phi_1\}, \{\phi_2\}, \{\phi_3\},$ and $\{\phi_4\}$

To study the dynamic property of the two equations $f(x)$ and $g(x)$, we drew the graph of the two equations under a greater of number of random parameters. Due to the similarity, only the graphs of $f(x)$ and $g(x)$ with $(\alpha_1, \alpha_2) = (2.10155, 3.56922)$, $(\alpha_3, \alpha_4) = (61.522, 257.26223)$ are shown in Fig. 6. Comparing the graphs of the two functions and $y = x$, one can assure that the states generated by iterating the two functions will approach zero soon after some iterations.

Figure 6: The graph of $f(x)$ and $g(x)$.

To further test the randomness of the sequences generated by the two equations, we adopted the test suite proposed in [23]. Since the three sequences $\{\phi_1\}$, $\{\phi_2\}$, and $\{\phi_4\}$ are determined by the same equation, only the randomness of $\{\phi_3\}$ and $\{\phi_4\}$ was tested.
For every sequence, 100 samples of length $512 \cdot 512/8 = 32768$ (the number of bytes used for encryption of a gray-scale plain-image of size $512 \times 512$) were generated by random secret keys. For each test, the default significance level 0.01 was adopted. The results are shown in Table 1, from which one can see that the two equations both cannot be used as a good random number generator.

Table 1: The performed tests with respect to a significance level 0.01 and the number of sequences passing each test in 100 randomly generated sequences.

| Name of Test                  | $f(x)$ | $g(x)$ |
|------------------------------|--------|--------|
| Frequency                    | 6      | 2      |
| Block Frequency ($m = 100$)  | 10     | 6      |
| Cumulative Sums-Forward      | 6      | 3      |
| Runs                         | 8      | 3      |
| Rank                         | 68     | 99     |
| Non-overlapping Template ($m = 9, B = 110001000$) | 76     | 64     |
| Serial ($m = 16$)            | 6      | 9      |
| Approximate Entropy ($m = 10$) | 8   | 6      |
| FFT                          | 65     | 49     |

- **Insensitivity with Respect to Changes of Plaintext**

In [21, Sec.5.4], the importance of sensitivity with respect to changes of plaintext is recognized. However, the encryption scheme under study is actually very far away from the desired property. In cryptography, the most ideal situation about sensitivity is that the change of any single bit of plaintext will make every bit of the corresponding ciphertext change with a probability of one half. Obviously, the encryption scheme under study can not reach the desired state due to the following points.

- No nonlinear S-box is involved in the whole scheme;
- Any bit of plaintext only may influence the bits at the above levels in the ciphertext;
- Any pixel of plaintext does not influence other pixels in the corresponding ciphertext uniformly.

To demonstrate this defect efficiently, we performed an experiment by changing a bit of the plain-image of size $512 \times 512$ shown in Fig. 3c). It is found that only the bits of one level are changed. The locations of the changed bits are shown in Fig. 7, where the white dots denote changed locations and black ones denote unchanged ones.

![Figure 7](image-url)

Figure 7: The locations of changed bits of the cipher-image, when the 5-th bit of the pixel at location (256, 256) in the plain-image was changed.
4 Conclusion

In this paper, the security of a chaotic cryptographic scheme based on composition maps has been studied in detail. It is found that the scheme can be broken with \(6 + \lceil \log_L(MN) \rceil\) chosen-plaintext. In addition, the scheme is not sensitive to the changes of plaintext also. Furthermore, the randomness of the pseudo-random number sequences generated by the composition maps is very weak. Due to the insecurity of the scheme under study, it is should not be used in real serious application.
