Generalized boundary conditions for general relativity for the asymptotically flat case in terms of Ashtekar's variables

Received 28 July 1994

Abstract. There is a gap that has not been filled since the formulation of general relativity in terms of Ashtekar's new variables, namely the treatment of asymptotically flat field configurations that are general enough to be able to define the generators of the Lorentz subgroup of the asymptotic Poincaré group. While such a formulation already exists for the old geometrodynamical variables, up to now only the generators of the translation subgroup have been able to be defined, because the function spaces of the fields considered earlier are taken in too special a form. The transcription of the framework from the ADM variables to Ashtekar's variables turns out not to be straightforward, due to the a priori freedom to choose the internal SO(3) frame at spatial infinity, and due to the fact that the non-trivial reality conditions of the Ashtekar framework re-enter the stage when imposing suitable boundary conditions on the fields and the Lagrange multipliers.

1. Introduction

Since the advent of the new canonical variables introduced by Ashtekar [1] the majority of related contributions have dealt, within the canonical treatment of gravity, with the case of a compact topology of the initial data hypersurface without boundary because it is technically simpler, although the major problem of general relativity, that of defining what is and how to construct an observable, is even more severe than for the case of an asymptotically flat topology, since one then does not even have access to the well known surface observables at spatial infinity ('spi', not to be confused with the universal structure at spatial infinity which is called 'Spi' [3]).

Although there already exists an initial value formulation for the asymptotically flat context [1], the stress in these former contributions was more on other issues related to the canonical formulation, so that the treatment given there turned out to be rather restrictive. In particular, the asymptotic Lorentz group cannot be implemented with those means. This paper is meant to fill that gap.

In section 2 we review the framework given in [2], since there we find an explicit and consistent definition of the generators of the asymptotic Poincaré group. The calculations and definitions that follow will all be based on, and motivated by, the results of that paper.

‡ E-mail address: thiemann@phys.psu.edu
In section 3 we propose a transcription of the definition of the function spaces of the basic fields from the geometrodynamical to Ashtekar's variables. The challenge is that there is now more asymptotic structure available, since we are a priori free to choose the internal $SO(3)$ frame. It turns out, however, that in order to recover the ADM-energy as given in [2] requires us to fix the asymptotic internal frame. This is satisfactory, because an 'SO(3) charge' should not play any role in general relativity.

The correction for the generating functional of the symplectomorphism from the old to the new variables compared with that in [1] is obtained.

In section 4 we derive the generators of the Poincaré group for the new variables. These are constructed from the constraint functionals by the requirement that they should be finite and functionally differentiable (together with the symplectic form) on the full phase space. Now, the virtue of the new variables is that the constraint functions turn out to be polynomial. Furthermore, with the function spaces considered in [1], the translation generators also turn out to be polynomial in the new variables. The main result is that if one wants to include boosts and rotations in the framework, the Poincaré generators necessarily become non-polynomial. The constraint functions themselves, of course, remain polynomial, so that the main advantage of the new variables is not invalidated.

However, this non-polynomial nature of the Poincaré generators has an important consequence: it is not possible anymore, as stated frequently [1], to consider degenerate metrics (actually there is already a problem with degenerate metrics when imposing the reality conditions for Ashtekar's variables which involve the non-polynomial spin connection).

Altogether, what we do is just to perform the symplectomorphism from the ADM phase space to the Ashtekar phase space carefully, which in particular implies that on the constraint surface defined by the Gauss constraint all the results of [2] remain valid.

Section 5 checks that the Poincaré generators defined satisfy the correct gauge algebra, that they are Dirac observables [4] and that on the constraint surface one recovers the Lie algebra of the Poincaré group modulo the well known super-translation ambiguity.

Throughout it is assumed that the reader is familiar with the formulation of general relativity in terms of the new variables. For a review the reader is referred to [1]. We use the abstract index notation. All quantities that are defined with respect to the asymptotic frame at $\bar{\text{spi}}$ will carry an overbar (not to be confused with complex conjugation!).

2. Geometrodynamics in the asymptotically flat context

Here we mainly give a compact account of the results obtained in [2] for later reference, and since we want to compare the old and new formulation of general relativity. For more details the reader is referred to that paper.

The basic variables of the canonical formulation of general relativity for geometrodynamics are the intrinsic metric (or first fundamental form) $q_{ab}$ on the initial data hypersurface $\Sigma$, and its extrinsic curvature (or second fundamental form) $K_{ab}$ (more precisely the second basic variable is the momentum conjugate to $q_{ab}$, $p^{ab} := (\det(q))^{1/2} (q^{ac} q^{bd} - q^{ab} q^{cd}) K_{cd}$, where $q^{ab}$ is the inverse of $q_{ab}$). As usual for the discussion of asymptotic flatness [5], we will assume the topology of $\Sigma$ to be such that it is homeomorphic to the union of a compact set with a collection of 'ends' (i.e. asymptotic regions) where each end is homeomorphic to the complement of a compact ball in $R^3$. In the sequel we restrict ourselves to one end and by $\partial \Sigma = S^2$ mean only spatial infinity of that end. The treatment of the remaining regions is identical.

Let us introduce a local frame in the neighbourhood of $\bar{\text{spi}}$, denoted by $\{\bar{\mathcal{F}}^a\}$, and
Abbreviate the asymptotic ‘spherical’ variables by \( r^2 := \tilde{x}^a \tilde{x}^b \delta_{ab}, \phi^a := \tilde{x}^a / r \), where \( \phi^a \) coordinatizes \( \text{spi} \) (topologically \( S^2 \)). We do not take this frame to be necessarily Cartesian, but we assume that the transition matrix \( (\partial (x_{\text{cart}})^a / \partial \tilde{x}^b) \) mediating to the Cartesian one, \((x_{\text{cart}})^a\), is of order \( O(1) \).

Motivated by the appearance of the Schwarzschild solution, in these coordinates one defines

\[
q_{ab} \rightarrow \bar{q}_{ab} + \frac{f_{ab}}{r} + O\left(\frac{1}{r^2}\right)
\]

(2.1)
as \( r \to \infty \), and it is assumed that the tensors \( \bar{q}_{ab}, f_{ab} \) are smooth on \( \text{spi} \) (\( \bar{q}_{ab} \) is the Euclidean metric in the asymptotic frame, and it is assumed to be non-dynamic, i.e. it is taken, as well as \( \bar{\partial} \), as the ‘first order part of the asymptotic structure at \( \text{spi} \)’ [3]).

In order to derive the asymptotic behaviour of \( p^{ab} \) one seeks to make the symplectic structure

\[
\Omega := \int_{\Sigma} d^3x \, dp^{ab}(x) \wedge dq_{ab}(x)
\]

(2.2)
well defined (recall that for an integral curve \( \gamma \) with parameter \( t \) on the phase space, the gradient of \( q_{ab} \) is defined by \( dq_{ab}(x)(\partial / \partial t)_\gamma := q_{ab}(x)_{\gamma t} \) and similarly for the momentum variable). Furthermore, one wants to have the ADM momentum to be non-vanishing (see formula (2.9)). This implies that the leading order part of \( p^{ab} \) must be \( O(1/r^2) \). However, the symplectic structure is then logarithmically divergent in general. This can be cured by imposing that the leading order parts of the dynamical parts of the basic variables should have opposite parity. Since for an asymptotic translation lapse and shift are even functions at \( \text{spi} \) of order 1, the only way to have the ADM 4-momentum non-vanishing is to impose that \( f_{ab} \) is even while \( h^{ab} \) is odd (and smooth) at \( \text{spi} \), where

\[
p^{ab} \rightarrow \frac{h^{ab}}{r^2} + O\left(\frac{1}{r^3}\right)
\]

(2.3)
in order to see this, recall that the surface integrals are first evaluated at finite \( r \) and then one carries out the limit \( r \to \infty \). We then have \( dS_u := \frac{1}{2} \epsilon_{abc} d\tilde{x}^b \wedge d\tilde{x}^c = u_a r^2 d\mu, \) where \( \mu \) is the standard measure at \( \text{spi} \), \( u_a \) is the outward unit normal at \( \text{spi} \), and \( \epsilon_{abc} \) is the (metric independent) alternating symbol, i.e. \( dS_u \) is ‘odd’.

The constraint functionals of source-free general relativity in the old ADM variables are given by

\[
V_u[N^a] = \int_{\Sigma} d^3x \, N^a (-2D_b p^b_u)
\]

(2.4)
called, respectively, the vector and the scalar constraint. Here we have introduced the components tangential \((N^a)\), the shift vector and perpendicular \((N, \) the lapse function) to the hypersurface \( \Sigma \) of the vector field defining the foliation (with parameter \( t \)) and \((3)R \) is the scalar curvature of \((\Sigma, q_{ab})\). It is understood that all indices are raised and lowered with the intrinsic metric whose unique torsion-free covariant differential is given by \( D \).

The vanishing of these constraint functionals defines the constraint surface \( \Xi \) of the phase space. Since these constraints turn out to be first class in Dirac’s terminology (more precisely, \( \Xi \) is a co-isotropic submanifold of \( \Gamma \)), they will generate gauge transformations, and so define the reduced phase space \( \hat{\Gamma} \) by identifying points in \( \hat{\Gamma} \) which lie on the same
flow line of the Hamiltonian vector fields associated with the constraint functionals. It follows that one needs to compute Poisson brackets with these constraint functionals.

In order that one can compute Poisson brackets of these constraint functionals with various functions on the phase space, they have to be:

1. finite, i.e. the integrals have to converge;
2. functionally differentiable.

Inserting the fall-off behaviour of our two basic fields into the equations (2.4), (2.5) one discovers that the integrals diverge, in general, if one does not restrict the fall-off of the 'Lagrange-multipliers' \((N^a, N)\), too. There is no problem if one chooses them with, say, compact support, but then the ADM 4-momentum (to be defined shortly) vanishes identically. In order to account for the generators of the asymptotic Poincaré group, the most general behaviour of lapse and shift that one would like to incorporate into the analysis is as follows:

\[
N^a \rightarrow a^a + \tilde{a}^a_{bc} \varphi^b \delta^c + \text{super-translations}
\]

Here \((a^a, a)\) are the parameters of the translation subgroup, \(\varphi^a\) are rotation angles, and \(\beta^a\) are boost angles \(\hat{e}_{abc} := \sqrt{\det(q)} e_{abc}\). These are vectors in asymptotic \(R^3\), i.e. constants, while the super-translation parameters (to be specified in more detail shortly) are genuinely angle dependent functions on \(S^2\) (for more information about the super-translation ambiguity, see [3, 6]).

However, now the above generators of gauge transformations fail to be (manifestly) well defined, nor are they functionally differentiable. This can be cured by using the following procedure.

Vary the basic fields and obtain expressions proportional to \(\delta q_{ab}, \delta p^{ab}\). In doing this one picks up a surface integral. If the volume term of the variation is well defined, it gives the sought functional derivative of the functional that we are seeking to make well defined. Subtract the surface term from the variation of the original constraint. If then, finally, the surface term obtained turns out to be exact, i.e. can be written as the variation of an ordinary surface integral, one has obtained this expression which is functionally differentiable and, if one is lucky, is already (manifestly) finite.

Let us exemplify this for the vector constraint: \(D_b p_a^b\) is \(O(1/r^3)\) and even, so even for an asymptotic translation the integral in (2.4) diverges logarithmically. Upon variation we obtain

\[
\delta V_a[N^a] = \int_{\Sigma} d^3 x \left( L_{\tilde{N}} q_{ab} \delta p^{ab} - L_{\tilde{N}} p^{ab} \delta q_{ab} \right) + 2 \int_{\partial \Sigma} N^a \delta p^b_a. \tag{2.7}
\]

The volume part is obviously already finite: since \(\tilde{N}\) is an asymptotic Killing vector of \(\tilde{q}_{ab}\), we have \(L_{\tilde{N}} q_{ab} = O(1/r^2)\) odd and \(O(1/r)\) even for an asymptotic translation or rotation, respectively, while \(\delta p^{ab} = O(1/r^2)\) odd. Hence \(L_{\tilde{N}} p^{ab} = O(1/r^3)\) even and \(O(1/r^2)\) odd for an asymptotic translation or rotation, respectively, while \(\delta q_{ab} = O(1/r)\) even. Hence, the integrand is either \(O(1/r^4)\) even or \(O(1/r^5)\), odd and so converges.

On the other hand \(N^a \delta p^b_a = \delta (N^a p^b_a)\), so the surface term is indeed exact. Hence our candidate for a finite and functionally differentiable vector constraint arises from subtracting the corresponding counter-term:

\[
H_a[N^a] := V_a[N^a] + 2 \int_{\partial \Sigma} N^a \delta p^b_a = \int_{\Sigma} d^3 x L_{\tilde{N}} q_{ab} p^{ab} \tag{2.8}
\]

where we have carried out an integration by parts in the second step. This functional is differentiable by construction, and luckily already finite since (by the same argument as above) the integrand is either \(O(1/r^4)\) even or \(O(1/r^5)\) odd. The surface term in (2.8)
defines the ADM momentum for an asymptotically constant shift, the integrand is O(1) even, and hence does not vanish:

\[ 2 \int_{\Sigma} dS_b N^a p^b_a =: a^a P_a \quad (2.9) \]

while for an asymptotic rotation we obtain

\[ 2 \int_{\Sigma} dS_b N^a p^b_a =: \varphi^a \tilde{\eta}_{abc} x^b P^c \quad (2.10) \]

which qualifies \( J^a := \tilde{\eta}_{abc} x^b P^c \) as the asymptotic angular momentum.

For the scalar constraint one proceeds similarly. The difference is that due to the appearance of second spatial derivatives in \( (\partial_t) R \) one has to do an integration by parts twice in order to arrive at a well defined variation of the scalar constraint. The final result is given by \[2\]

\[ H[N] := C[N] + 2 \int_{\Sigma} dS_d \sqrt{\det(q)} q^{ac} q^{bd} [N \tilde{D}_{[c} q_{b]} - (q_{a[b} - \tilde{q}_{a[b}) \tilde{D}_{c]} N] \quad (2.11) \]

where \( \tilde{D} \) is the unique torsion-free covariant differential compatible with \( \tilde{q}_{ab} \). The first part of the surface integral is called the ADM energy for an asymptotic time-translation

\[ E := 2 \int_{\Sigma} dS_d \sqrt{\det(q)} q^{ac} q^{bd} \tilde{D}_{[c} q_{b]} \quad (2.12) \]

while the second part then vanishes. Otherwise we obtain the boost generator

\[ \beta_e K^e := \beta_e \left( E \tilde{x}^e - 2 \int_{\Sigma} dS_d \sqrt{\det(q)} q^{ac} q^{bd} (q_{a[b} - \tilde{q}_{a[b}) \delta_e^c \right) . \quad (2.13) \]

Note that since gauge transformations are those for which the generators \( H, H_a \) induce identity transformations at \( \text{spi} \) on the constraint surface, they then have to vanish. Thus, only the odd part of the supertranslation parameters are non-vanishing in this case (the integrand without the Lagrange multipliers is even). In the remainder we will therefore consider the following fall-off behaviour of the Lagrange-multipliers:

\[ N^a := T^a + R^a + S^a = T^a + \tilde{\eta}_{ab} \varphi^b x^e + S^a \quad (2.14) \]

where \( (T, T^a) \) are O(1) even, i.e. generate an asymptotic translation in four-dimensional space, \( B, R^a \) are O(\( r \)) odd, i.e. generate asymptotic boosts and rotations, and finally \( (S, S^0) \) are O(1) and odd, at least in leading order, and thus generate the odd super-translations. Moreover, introducing the future-directed, timelike unit normal to the initial data hypersurface \( \Sigma \), related to lapse and shift according to \( (\partial_t) r^a = N n^a + N^a \), the vector field \( (T + B) n^a + (T^a + R^a) \) is required to be a (ten parameter) Killing vector field of the asymptotic spacetime metric \( \tilde{g}_{ab} = \tilde{q}_{ab} - \tilde{n}_a \tilde{n}_b \), which implies, in particular, that \( \mathcal{L}_{\tilde{x}} q_{ab} \) is O(1/\( r^2 \)) odd and that \( \mathcal{L}_{\tilde{x}} q_{ab} \) and \( \mathcal{L}_{\tilde{x}} q_{ab} \) are O(1/\( r \)) even. These properties will be used in the following.

### 3. Connection dynamics in the asymptotically flat context

We begin by transcribing the boundary conditions imposed on the ADM variables to the new variables. In the following, latin letters from the beginning of the alphabet will denote tensor indices while latin letters from the middle of the alphabet will denote (internal) \( SO(3) \) indices.
Recalling that the triad 1-form is the square root of the 3-metric, we expect the following fall-off behaviour:

\[ e_i^a \rightarrow \tilde{e}_i^a + \frac{f_i^a(\phi^b)}{r} + O\left(\frac{1}{r^2}\right) \tag{3.1} \]

where we have called the triad of the asymptotic 3-metric at spi \( \tilde{e}_i^a \). In order to investigate what the relation between the smooth tensors \( f_{ab} \) and \( f_a^i \) on spi is, we compute the 3-metric

\[ g_{ab} = \delta_{ij}e_i^a e_j^b = \tilde{g}_{ab} + 2 \frac{\delta_{ij} \tilde{e}_a^i f_b^j}{r} + O\left(\frac{1}{r^2}\right) \tag{3.2} \]

from which we infer

\[ f_{ab} = 2\delta_{ij} \tilde{e}_a^i f_b^j. \tag{3.3} \]

This has the solution

\[ f_a^i = \left(\frac{1}{2} f_{ab} + \tilde{n}_{abc}^i v^c\right) \tilde{e}_b^i \tag{3.4} \]

where \( v^a \) is a smooth vector field at spi.

Since the parity of \( f_{ab} \) is even, \( \tilde{e}_a^i \) and \( f_a^i \) must have equal parity. Note that we do not require \( \tilde{e}_a^i \) to be a constant (it can be angle dependent). Also, the vector field \( v^a \) is not constrained at all up to now.

Since (if the Gauss constraint is satisfied) \( K_a^i = K_{abc} e_b^c \) we need the asymptotic formula for the inverse triad. From the requirement \( q^{ac} q_{cb} = \tilde{q}_b^b \) we obtain unambiguously

\[ q^{ab} = \tilde{q}^{ab} - \tilde{q}^{ac} \tilde{q}^{bd} \frac{f_{cd}}{r} + O\left(\frac{1}{r^2}\right) \tag{3.5} \]

whence

\[ e_i^a = q^{ab} e_b^i = \tilde{e}_i^a - \frac{1}{2} \tilde{q}^{ac} f_{bc} - \tilde{n}_{abc}^i v^c \tilde{e}_b^i. \tag{3.6} \]

Accordingly we obtain

\[ K_a^i = \frac{h_{ab} (\phi^c) \tilde{e}_b^i}{r^2} + O\left(\frac{1}{r^3}\right) \tag{3.7} \]

and the smooth tensor \( h_{ab} \) at spi has odd parity.

Finally, in order to derive the asymptotic formula for the Ashtekar connection we need to determine the asymptotics for the spin connection \( \omega_a^i \). First of all we extend the covariant derivative \( D \) to generalized tensors in the usual way, e.g.

\[ D_a e_b^i := \tilde{D}_a e_b^i - \Gamma^c_{ab} e_c^i + \omega_a^i e_b^i = 0 \tag{3.8} \]

where \( \tilde{D} \) is the covariant differential, extended to generalized tensors, that annihilates \( \tilde{e}_a^i \) and \( \tilde{q}_{ab} \). Note that this implies that the spin- and metric-connections of \( e_a^i \) are \( O(1/r^2) \) while those of \( \tilde{e}_a^i \) are only \( O(1/r) \) (it will turn out, however, that asymptotic internal rotations vanish identically in gravity (see next section) so that the spin connection of \( \tilde{e}_a^i \) vanishes identically, as can easily be seen when going to the Cartesian frame for which \( \tilde{q}_{ab} = \delta_{ab} \) and \( \tilde{e}_a^i = \delta_a^i \).

From the torsion-freeness requirement \( \tilde{D} \wedge e^i + \omega_j^i \wedge e^j = 0 \) we easily infer (\( \tilde{D} \) acts on tensor—and \( SO(3) \)—indices)

\[ r^2 \tilde{D}_a e_b^i + \lambda^{ia} e_b^i + \nu^{ia} \tilde{e}_b^i = 0 \tag{3.9} \]
where we have denoted the leading order part of the spin connection by $\lambda_a^i$. Since $\overline{D}_b f_a^i$ and $\tilde{e}_a^i$ have opposite parity, this formula can only hold if $\lambda_a^i$ has odd parity.

This may also be checked explicitly: inverting formula (3.8), the analytic expression for the spin connection in terms of the triads is given by (as usual, we define $\Gamma_a^i := -\frac{i}{2} \epsilon^{ijk} \omega_{a jk}$)

$$\Gamma_a^i = -\frac{1}{2} \epsilon^{ijk} e_j^b (2\overline{D}_[a] e_{b]}^i + \epsilon^c_e \epsilon^d_d \overline{D}_c^i e^e_e)$$

from which we immediately derive

$$\lambda_a^i = -r^2 \frac{1}{2} \epsilon^{ijk} e_j^b \left(2\overline{D}_[a] f_{b]}^i + \epsilon^c_e \epsilon^d_d \overline{D}_c^i f_{b]}^i \right).$$

Since this is an even polynomial in $\tilde{e}_a^i$ and $f_a^i$ (both of which have equal parity), homogenous of first degree in the spatial derivatives, and $r$ is an even function at spi, expression (3.11) is altogether an odd quantity. Hence, it follows directly from the formula for the Ashtekar connection, $A_a^i = \Gamma_a^i + iK_a^i$, that its leading order part $G_a^i$, where

$$A_a^i = \frac{G_a^i}{r^2} + O\left(\frac{1}{r^3}\right)$$

has definite parity if and only if the leading order part of $K_a^i$ is odd, i.e. if and only if $\tilde{e}_a^i$ is even.

Since the second variable of the new canonical formulation of general relativity is given by $E_a^a := \sqrt{\det(q)} e_a^i$, i.e.

$$E_a^a = E_a^a - \sqrt{\det(q)} \left(\frac{1}{2} \tilde{q}^{ac} f_{bc} - \tilde{e}_a^a \nu^c + \tilde{q}^{bc} f_{bc} \tilde{e}_a^a \tilde{e}_b^b + O\left(\frac{1}{r^2}\right)\right) =: E_a^a + F_a^a + O\left(\frac{1}{r^2}\right).$$

we see that the next to leading order part $F_a^i$ has definite parity if and only if we set $\nu^a = 0$. This parity is, fortunately, even if we want $G_a^i$ to have definite (odd) parity. Hence, it is possible to choose parity conditions in such a way that $A_a^i E_a^a$ is asymptotically an odd scalar density without violating that $E_a^a$ and $A_a^i$ have to come from $g_{ab}$ and $K_{ab}$; however, these parity conditions are rather awkward: they imply that $E_a^a$ becomes asymptotically a pseudo-vector density while $A_a^i$ is asymptotically a true covector. Moreover, parity conditions cannot be reversed if one wants to make the Ashtekar formulation meaningful in the asymptotically flat context, just as for the old ADM formulation.

As one can check, the symplectic form is already finite, thanks to our parity conditions (we set the gravitational coupling constant equal to one in the following):

$$\Omega := \int_{\Sigma} d^3x \ (\ -i\ ) \ dE_a^a \wedge dA_a^i \rightarrow (\ -i\ ) \int_{\Sigma} d^3x \left[ \frac{dF_a^a}{r^3} \wedge dG_a^i}{r^3} + O\left(\frac{1}{r^4}\right)\right],$$

Recalling that the Ashtekar action arises from a complex canonical transformation, we ask if it is still true that its generating functional is given by $\int_{\Sigma} d^3x E_a^a \Gamma_a^i$, which was the case for the boundary conditions discussed by Ashtekar [1]. But it is obvious that this functional diverges logarithmically, without further specification. Indeed, using the explicit expression (3.10) we compute

$$2E_a^a \Gamma_a^i = \epsilon^{abc} e_c^i \overline{D}_b e_a^i \rightarrow \frac{r^2 \epsilon^{abc} e_c^i \overline{D}_b (f_a^i / r)}{r^2} + O\left(\frac{1}{r^3}\right)$$
and the first term vanishes, since $\overline{D}_a e^i_b = 0$ and $f_{ab}$ is symmetric, while the second has no definite parity. We can cure this simply by applying the following trick: using that $\overline{D}_a e^i_b = 0$ we can write

$$2E^a_i \Gamma^i_a = \epsilon^{abc} e^i_a \overline{D}_b e^i_a$$

$$= \epsilon^{abc} e^i_a \overline{D}_b (e^i_a - \overline{e}^i_a)$$

$$= \overline{D}_b (\epsilon^{abc} e^i_c (e^i_a - \overline{e}^i_a)) = \epsilon^{abc} (\overline{D}_b e^i_c)(e^i_a - \overline{e}^i_a)$$

$$= \delta_b (\epsilon^{abc} e^i_c (e^i_a - \overline{e}^i_a)) = \epsilon^{abc} (\overline{D}_b e^i_c)(e^i_a - \overline{e}^i_a).$$ (3.16)

The second term in the last line is manifestly $O(1/r^3)$ and odd, so gives a convergent integral, while the first yields a surface integral. Accordingly, we propose to define the generating functional for the spin connection by

$$\int d^3x \ E^a_i \Gamma^i_a - \frac{1}{2} \int d^3x \ L_b (\epsilon^{abc} e^i_c (e^i_a - \overline{e}^i_a))$$ (3.17)

and we can quickly check that this expression is indeed functionally differentiable, and that the functional derivative is precisely the spin connection. To see this, vary the integrand of the volume integral to obtain two terms

$$\delta (E^a_i \Gamma^i_a) = \Gamma^i_a \delta E^a_i + E^a_i \delta \Gamma^i_a.$$ (3.18)

The first is already the required one, while the second can be written (after tedious calculations) as

$$E^a_i \delta \Gamma^i_a = \frac{1}{2} \delta_a (\epsilon^{abc} e^i_b \delta e^i_c).$$ (3.19)

Varying the surface term on the other hand (recall that the asymptotic triad is non-dynamical, i.e. $\delta \overline{e}^i_a = 0$) yields

$$- \frac{1}{2} \int_{\partial \Sigma} d\Sigma (\epsilon^{abc} [(e^i_a - \overline{e}^i_a) \delta e^i_c + e^i_c \delta e^i_a] = - \frac{1}{2} \int_{\partial \Sigma} d\Sigma \epsilon^{abc} e^i_b \delta e^i_c$$ (3.20)

where the first term in the first line of (3.20) has dropped out because it is finite and odd. Comparing this result with equation (3.19) we observe that the two terms cancel exactly.

4. The Poincaré generators for the new variables

The final task is now to make the constraints convergent and functionally differentiable. We begin with the Gauss constraint:

$$\mathcal{G}_i := \overline{D}_a E^a_i + \epsilon_{ijk} A^j_a E^a_k.$$ (4.1)

The first term is $O(1/r^2)$ while the second is $O(1/r^3)$ and the whole expression is odd. Hence we need only worry about the first term whose variation, when integrated against the Lagrange multiplier $\Lambda^i$, is just given by

$$\int_{\partial \Sigma} d\Sigma A^j_a \delta E^a_j.$$ (4.2)

Recalling that $\Lambda^i$ is nothing else than the time component of the self-dual part of the four-dimensional spin connection, we require that it is $O(1/r^2)$ even for a symmetry transformation (there are therefore no asymptotic internal rotations!). Hence, the Gauss constraint is already finite and functionally differentiable if we further require that $\Lambda^i$ be even. This parity condition is also consistent with the interpretation of $\Lambda^i = (\partial/\partial t)\alpha^{(4)} A_a$.
because it is the contraction of an odd vector with an odd covector. There is thus no need for the $SO(3)$ charge

$$Q := \int_{\Sigma} dS_a E^a_i \Lambda^i$$

(4.3)

which then vanishes, anyway, due to parity, and whose variation is also zero. Note, however, that for model systems which do not have access to parity (e.g. spherically symmetric gravity [7]) the $SO(3)$ charge is non-vanishing and gives a spurious observable, which is fortunately unnecessary (the $SO(3)$ charge should play no role in general relativity).

The treatment of the vector and scalar constraint turns out to be much more difficult and differs from the one given in [1]. This is to be expected, because the generating functional (3.17) of the canonical transformation to the new canonical variables as given here is different from the one given in [1]. It gives rise to additional terms in the action, both in the volume and the surface part.

It turns out to be the easiest strategy, in finding the necessary modifications, to take the old ADM action in its manifestly finite and functionally differentiable version, and then to express it in terms of the new variables. We cannot expect it to remain well defined, because there are now 'more' variables. However, using the gauge constraint, we must be able to restrict the variations of the constraints to those of the ADM phase space. This is the outline of the idea, let us now come to the technical part of it.

Let us start with the expression (2.8), the generator of asymptotical spatial translations and rotations. We have

$$H_a[N^a] = \int_{\Sigma} d^3 x \ p^{ab} L_\hat{N} q_{ab} = - \int_{\Sigma} d^3 x \ p_{ab} L_\hat{N} q^{ab}$$

$$= - \int_{\Sigma} d^3 x \ p_{ab} L_\hat{N} \left( \frac{E^a_i E^b_i}{\det(q)} \right)$$

$$= - \int_{\Sigma} d^3 x \ \frac{P_{ab}}{\det(q)} \left[ 2 E^b_i L_\hat{N} E^a_i - E^a_i E^b_i (E^{-1})_i L_\hat{N} E^a_i \right]$$

$$= - 2 \int_{\Sigma} d^3 x \ [ (K_{ab} - K q_{ab}) e^b_i + K e^a_i ] L_\hat{N} E^a_i$$

$$= - 2 \int_{\Sigma} d^3 x \ K^a_i L_\hat{N} E^a_i$$

(4.4)

where we have used the elementary fact that

$$p^{ab} L_\hat{N} q_{ab} = p^{ab} L_\hat{N} (q_{ac} q_{bd} q^{cd}) = 2 p^{ab} L_\hat{N} q_{ab} + p_{ab} L_\hat{N} q^{ab} = - p_{ab} L_\hat{N} q^{ab}$$

that $\det(q) = \det(E^a_i)$, and the definition of the momentum conjugate to the 3-metric in terms of the extrinsic curvature (it seems as if up to now we have only used differential geometric identities, but actually we have made use of the Gauss constraint in order to replace the variable $K_{ab}$ by $K^a_i$).

Finally we use the reality conditions in order to write (3.4) in terms of the Ashtekar connection:

$$H_a[N^a] = 2i \int_{\Sigma} d^3 x \ (A^i_a - \Gamma^i_a) L_\hat{N} E^a_i$$

(4.5)

Noting that $E^a_i$ is a vector density of weight one, we have $L_\hat{N} E^a_i = D_b N^b E^a_i + N^b D_b E^a_i - E^a_i D_b N^b$, and this expression is obviously $O(1/r)$ odd for an asymptotic translation while it
is $O(1)$ even for an asymptotic rotation (note that this expression is correct precisely because the spin connection of $\delta^i_j$ vanishes, in principle $\mathcal{D}$ acts on internal indices which, however, are not involved in the definition of the Lie derivative). Hence the integral (4.5) diverges in either of these cases! To see how this comes about, we compute the Lie derivative of the twice densitized inverse asymptotic metric in terms of the electric fields

$$0 = \mathcal{L}_{\vec{N}} (\text{det}(\hat{q}) q^{ab}) = 2 \mathcal{E}^a_i (\mathcal{L}_{\vec{N}} \overline{E}^b_i)$$

(4.6)

which vanishes, since $\vec{N}$ is an asymptotic Killing vector of $\hat{q}_{ab}$. Thus, we see the source of the divergence in (4.5): the fact that $\vec{N}$ is an asymptotic Killing vector does not imply that $\overline{E}^a_i$ is also Lie-annihilated, but only that it is asymptotically rotated in the tangent space:

$$\mathcal{L}_{\vec{N}} \overline{E}^a_i = \overline{\eta}_{bc}^a \xi^b \overline{E}^c_i \quad \text{i.e.} \quad \xi_a = \frac{1}{2\text{det}(\hat{q})} \overline{\eta}_{abc} \mathcal{E}^b_i \mathcal{L}_{\vec{N}} \overline{E}^c_i$$

(4.7)

is $O(1/r)$ odd or $O(1)$ even for an asymptotic translation or rotation respectively. In order to isolate the divergence in (4.5) we write

$$K^i_a \mathcal{L}_{\vec{N}} E^a_i = K^i_a \mathcal{L}_{\vec{N}} (E^a_i - \overline{E}^a_i) + K^i_a \mathcal{L}_{\vec{N}} \overline{E}^a_i$$

$$= K^i_a \overline{\eta}_{bc}^a \xi^b \overline{E}^c_i + \text{finite}$$

$$= K^i_a \epsilon^{ijk} \overline{E}^b_j \overline{E}^c_k \sqrt{\text{det}(\hat{q})} + \text{finite}$$

$$= (\epsilon^{ijk} K^i_a \overline{E}^b_j \overline{E}^c_k + K^i_a \epsilon^{ijk} [\overline{E}^b_j - E^b_j] \overline{E}^c_k) \sqrt{\text{det}(\hat{q})} + \text{finite}$$

$$= \frac{1}{4} G_i \overline{E}^b_i \frac{\xi_b}{\sqrt{\text{det}(\hat{q})}} + \text{finite}$$

(4.8)

where we have absorbed terms that are either $O(1/r^4)$ even or $O(1/r^3)$ odd into the expression “finite”. Thus we have managed to peel out the contribution that causes trouble in (4.5): as expected, it is something proportional to the Gauss constraint, and hence plays no role on the constraint surface.

We are then motivated to consider as a candidate for a well defined symmetry generator corresponding to the vector constraint (using the same label)

$$K_a[N^a] := 2i \int \frac{d^3x}{\Sigma} \left[ (A^i_a - \Gamma^i_a) \mathcal{L}_{\vec{N}} E^a_i - \frac{1}{\text{det}(\hat{q})} E^a_i \xi_a G_i \right]$$

(4.9)

where $\xi_a := (1/(2\text{det}(\hat{q}))) \overline{\eta}_{abc} \mathcal{E}^b_i \mathcal{L}_{\vec{N}} \overline{E}^c_i$. The reader might worry about the highly non-polynomial appearance of (4.9) but, as we will show, the constraints remain polynomial, and this is the important feature to keep when thinking of quantizing general relativity [4].

Note that we have ‘unbarred’ everything in (4.9), as compared with (4.8), which we justify now by direct computation, thereby showing that (4.9) is well defined and differentiable. By simply using the definitions we verify that the integrand of (4.9) is given by

$$(E^{-1})^b_c (A^i_a - \Gamma^i_a) \mathcal{L}_{\vec{N}} (\text{det}(\hat{q}) q^{ab})$$

(4.10)

which is $O(1/r^3)$ odd or $O(1/r^4)$ even, repectively, and thus yields a convergent integral, thanks to the fact that $\vec{N}$ is an asymptotic Killing vector (recall the discussion at the end of the previous section). Thus, we have already established finiteness.
In order to show that (4.9) is also already functionally differentiable, we first display the relation of (4.9) with the constraints. We have

\[- K_i^a \mathcal{L}_\gamma E_i^a = - \mathcal{L}_\gamma (K_i^a E_i^a) + E_i^a \mathcal{L}_\gamma K_i^a \]

\[= (N^b \overline{D}_b K_i^a + K_i^b \overline{D}_b N^b)E_i^a - \overline{D}_b (N^b K_i^a E_i^a) \]

\[= N^a (E_i^b \overline{D}_b K_i^b - \overline{D}_b (K_i^a E_i^a)) - 2 \overline{D}_b (N^b K_i^a) E_i^a \]

\[= - iN^a (2 E_i^b \overline{D}_b [a \Gamma_{ab}^i] - A_i^a \overline{D}_b E_i^b) - iN^a (2 E_i^b \overline{D}_b [a \Gamma_{ab}^i] - \Gamma_{ab}^i \overline{D}_b E_i^b) \]

\[+ 2i \overline{D}_b (N^b A_i^a - \Gamma_{ab}) E_i^a. \]  \hspace{1cm} (4.11)

Due to the definition of the spin connection we have $0 = D_a E_i^a = \overline{D}_a E_i^a + \varepsilon_{ijk} \Gamma_{ab}^j A_i^k$, so that the bracket of the second term in the last equation can be written

\[2 E_i^b \overline{D}_b [a \Gamma_{ab}^i] - \Gamma_{ab}^i \overline{D}_b E_i^b = E_i^b (2 \overline{D}_b [a \Gamma_{ab}^i] + \varepsilon_{ijk} \Gamma_{ab}^j \Gamma_{ab}^k) = E_i^b R_{ab} = 0 \]  \hspace{1cm} (4.12)

due to the first Bianchi identity. Accordingly, (4.11) can be rewritten in the form

\[- iN^a (F_{ab}^i E_i^b - A_i^a G_i) + 2i \overline{D}_b (N^b A_i^a - \Gamma_{ab}) E_i^a \]  \hspace{1cm} (4.13)

where $\frac{1}{2} F$ is the curvature of the Ashtekar connection and we have used the definition of the Gauss constraint (4.1). Since the variation of the action with respect to $A_i^a$ yields the Gauss constraint, the variation with respect to the shift vector field results in the diffeomorphism constraint, i.e. the 1st bracket in (4.13), for a shift corresponding to the generator of a gauge transformation (i.e. the shift is at most a supertranslation at spi). Hence the polynomial form of the constraints is not spoiled by the non-polynomial term in the full vector contraint

\[H_a [N^a] = - 2i \int_E d^3 x \left[ N^a (F_{ab}^i E_i^b - A_i^a G_i) + \frac{1}{\sqrt{\text{det}(q)}} E_i^a \xi_a G_i \right] \]

\[\cdots - 4i \int_{\partial \Sigma} dS_a [A_i^a - \Gamma_{ab}^i] N^b E_i^a \]  \hspace{1cm} (4.14)

Note that the surface term is not Ashtekar's expression [1] which is just that given in (4.14), but without the second term including the spin connection. It has the advantage of giving (modulo reality conditions) manifestly the ADM momentum. For a pure translation the surface term in (4.14) reduces to Ashtekar's expression, because in that case the second part of the integrand of the boundary term is exact:

\[4i dS_a \Gamma_{ab}^i N^b E_i^a = i dS_a N^b \epsilon^{acd} \overline{D}_c \frac{f_{bd}}{r} + O\left(\frac{1}{r}\right) = i d \wedge \left( N^b \frac{f_{bd}}{r} dx^d \right) + O\left(\frac{1}{r}\right) \]

which is $O(1)$ and even for a translation, moreover non-vanishing (only the integral over the sphere cancels it) and imaginary.

Let us now check functional differentiability of (4.14). Looking at the surface term that is picked up when varying (4.14) we obtain

\[\delta H_a [N^a]_{\delta \Sigma} = \int_{\partial \Sigma} \left[ - 4i dS_a \delta A_i^a N^a E_i^b + 2i dS_a A_i^a \delta E_i^b N^a \right. \]

\[- 2i (\text{det}(q))^{-1/2} (E_i^a \xi^a) \delta E_i^b dS_b \]

\[- i (\text{det}(q))^{-3/2} \Gamma_{ab}^i E_i^a H_{abc} E_j^b \mathcal{L}_N \delta E_j^a 4i dS_a (\delta A_{b}^i - \delta \Gamma_{ab}^i) E_i^b \]

\[- 4i dS_a (A_i^a - \Gamma_{ab}^i) N^b \delta E_i^b \]  \hspace{1cm} (4.15)
The first line comes from the variation of the polynomial part of the volume term, the second from its non-polynomial part, and the last line arises from varying the surface term. We observe that the first term of the first line cancels the first term in the first bracket of the last line. Furthermore, the second term of the first line as well as the complete last bracket of the last line, and the term proportional to the Gauss constraint in the middle line, vanish identically irrespective of the nature of the transformation due to parity or fall-off. Recalling the definition of $\xi^a$ we thus end up with

$$\delta H_a[N^a] = -2i \int_{\Sigma} dS_a \left[ \frac{1}{2[\det(q)]^{1/2}} E^b_i \eta_{bcd} E^d_j \mathcal{L}_{q} E^a_j - 2N^{[b} \delta(E_{ci}^a \Gamma_{ib}) \right]. \quad (4.16)$$

By using the explicit expression (3.10) for the spin connection in terms of the triads, it is easy to show that

$$E^a_i \Gamma_{ia} = \frac{1}{2} \varepsilon^{abc} e^i_c \overline{D}_b e^i_a, \quad E^a_i \Gamma_{ib} = \frac{1}{2} \varepsilon^{acd} (\overline{D}_c q_{bd} + e^i_c \overline{D}_b e^i_d). \quad (4.17)$$

Since the terms in which the underived parts are varied vanish due to parity or fall-off, we arrive after simple algebra at

$$\delta H_a[N^a] = i \int_{\Sigma} (\det(q))^{1/2} dS_a \left[ \eta^{acdef} N^b D_c N_d q_{ef} \delta q_{bc} \right. \nonumber$$

$$\left. - N^{[b}(D_d \delta q_{bc} - e^i_c D_b \delta e_d)) + \eta^{bcd} (e^i_c \delta e^i_d D_c N_d - N^a e^i_d D_c \delta e^i_b) \right] \quad (4.18)$$

where we have used $E^a_i = \sqrt{q} e^a_i$ in order to write everything in terms of variation of the triads, and we have been able to replace $\overline{D} \delta f$ by $D \delta f$ for any $f$ because the additional contributions included in $D$ fall off one order faster, while (4.18) is, anyway, either $O(1)$ even or $O(r)$ odd.

We will now discuss the three possibilities for the fall-off of the shift:

Case (1). Super-translation. (4.18) is $O(1)$ and odd, so vanishes identically.

Case (2). Translation. We have now $D_a N_b = O(1/r^2)$, so there are no contributions from these terms in (4.18), hence

$$\delta H_a[N^a] = -i \int_{\Sigma} (\det(q))^{1/2} dS_a \left[ \eta^{acdef} N^b (D_d \delta q_{bc} - e^i_c D_b \delta e_d) + \eta^{bcd} (e^i_c \delta e^i_d D_c N_d - N^a e^i_d D_c \delta e^i_b) \right]$$

By using the explicit expression (3.10) for the spin connection in terms of the triads, it is easy to show that

$$E^a_i \Gamma_{ia} = \frac{1}{2} \varepsilon^{abc} e^i_c \overline{D}_b e^i_a, \quad E^a_i \Gamma_{ib} = \frac{1}{2} \varepsilon^{acd} (\overline{D}_c q_{bd} + e^i_c \overline{D}_b e^i_d). \quad (4.17)$$

Since the terms in which the underived parts are varied vanish due to parity or fall-off, we arrive after simple algebra at

$$\delta H_a[N^a] = i \int_{\Sigma} (\det(q))^{1/2} dS_a \left[ \eta^{acdef} N^b (D_d \delta q_{bc} - e^i_c D_b \delta e_d) + \eta^{bcd} (e^i_c \delta e^i_d D_c N_d - N^a e^i_d D_c \delta e^i_b) \right]$$

The last term can be written

$$(\det(q))^{1/2} dS_a \eta^{acdef} N^b D \delta q_{bc}$$

$$= dx^c \wedge dx^d D_d (N^b \delta q_{bc}) + O\left(\frac{1}{r}\right) = d \wedge (N^b \delta q_{bc} dx^c) + O\left(\frac{1}{r}\right) \quad (4.20)$$

and thus drops out, since $\partial \partial \Sigma = 0$. The first term, on the other hand, can be cast into the form

$$(\det(q))^{1/2} dS_a (\eta^{acdef} N^a - \eta^{acdef} N^d) e^i_c D_b \delta e^i_c$$

$$= (\det(q))^{1/2} dS_a D_b [(\eta^{acdef} N^a - \eta^{acdef} N^d) e^i_c] \delta e^i_c + O\left(\frac{1}{r}\right)$$

$$= (\det(q))^{1/2} dS_a D_b \eta^{acdef} f_c + O\left(\frac{1}{r}\right) = d \wedge f + O\left(\frac{1}{r}\right) \quad (4.21)$$
where we have defined the 1-form $f_e := -\frac{1}{2} \eta_{eab}(\eta^{bcd} N^a - \eta^{acd} N^b) e^b_c$. Hence (4.19) is just the integral of an exact 1-form over an exact chain, and thus vanishes identically.

Case (3). Rotation. We now exploit $D_a N_b = \delta_{ab} \xi^e$, $D_a \xi^e = O(1/r^3)$. The idea is to integrate by parts in (4.19) and to order terms proportional to $N^a$ or $D_a N^b$. We thus have, using $D_a e^b_c = 0$,

$$\delta H_a[N^a] = \int_{\Sigma} (\det(q))^{1/2} dS_a \left[ \eta^{acd} \left( \frac{1}{2} q^{ef} \delta q_{ef} D_c N_d + \delta q_{bc} D_d N^b - e^b_i \delta e_d D_b N^b \right) \right. $$

$$+ \eta^{bcd} (e^b_i \delta e^a_c D_c N_d + e^a_i \delta e^b_c D_c N^a) + \eta^{acd} (-D_d (\delta q_{bc} N^b) + D_b (e^b_i \delta e_d N^b))$$

$$\left. - \eta^{bcd} D_e (e^i_d \delta e^b_c D_c N^a) \right].$$

(4.22)

We can write the last two brackets as follows:

$$(\det(q))^{1/2} dS_a \left[ -\eta^{acd} D_d (\delta q_{bc} N^b) - D_b ([\eta^{acd} N^b - \eta^{bcd} N^a] e^b_i \delta e_c) \right]$$

$$= (\det(q))^{1/2} dS_a \left[ -\eta^{acd} D_d (\delta q_{bc} N^b) - \eta^{abc} D_b (\eta e^d \eta^{bcd} N^c e^b_i \delta e_c) \right]$$

$$= (\det(q))^{1/2} dS_a \eta^{abc} D_b [\delta q_{bc} N^c - \eta e^d \eta^{bcd} N^c e^b_i \delta e_c]$$

(4.23)

and thus display it as an exact 2-form. Since we have regularized the surface integrals in such a way (see the remark in section 2) that they are to be evaluated at finite $r$ and then one takes the limit, we see that due to the fact that the sphere at finite $r$ is also without boundary, the integral over (4.23) drops out of (4.22). We are thus left with the first two brackets in (4.22). These turn out to cancel each other algebraically when using the above expression for $D_a N_b$:

$$\eta^{acd} \left( \frac{1}{2} q^{ef} \delta q_{ef} D_c N_d + \delta q_{bc} D_d N^b - e^b_i \delta e_d D_b N^b \right) + \eta^{bcd} (e^b_i \delta e^a_c D_c N_d + e^a_i \delta e^b_c D_c N^a)$$

$$= \xi^a q^{ef} \delta q_{ef} + 2 q e^c x f e^f q^{ab} \delta q_{bc} - 2 \xi^b e^a_i \delta e^i_b + 2 q e^d x f e^f q^{ae} e^b_i \delta e^i_b$$

$$= q^{ab} \xi^c \delta q_{bc} - \xi^b e^a_i \delta e^i_b - \xi^d q^{ab} e^i_c \delta e^i_b$$

$$= q^{ab} \xi^c (\delta q_{bc} - e^i_c \delta e^i_b) - \xi^b e^a_i \delta e^i_b$$

$$= q^{ab} \xi^c e^i_d \delta e^i_c - \xi^b e^a_i \delta e^i_b \equiv 0$$

(4.24)

where in the last step we have used $\delta q_{ab} = 2 e^{[a} \delta q_{b]}$.

Thus we have proved that (4.14) is finite, functionally differentiable, reduces to the ADM momentum on the constraint surface, and that its (weakly) vanishing part is polynomial in the basic variables. It therefore satisfies all requirements that one wishes to impose on a symmetry generator corresponding to momentum. We will prove in the next section that (4.14) generates the correct symmetries and gauge transformations.

Note. In principle one could also have found the correct version (4.14) of the vector-constraint in terms of Ashtekar's variables simply by carefully implementing the Gauss constraint, thus displaying (4.14) exactly as the old ADM momentum expression after doing the complex canonical transformation which leads to Ashtekar's theory: starting again from (2.8) we have

$$\int_{\Sigma} d^3 x \ p^{ab} L \bar{\eta} \eta^{ab} = - \int_{\Sigma} d^3 x \ p_{ab} L \bar{\eta} \eta^{ab}$$

$$= - \int_{\Sigma} d^3 x \ \sqrt{\det(q)} (K_{ab} - K q_{ab}) L \bar{\eta} \eta^{ab}$$
Thiemann

and it is important to see that only the symmetric part of the tensor $K_{ab}$ contributes to (4.25). The antisymmetric part, on the other hand, is directly related to the Gauss constraint: using the definition of $A^a_i$, $K^i_a := K_{ab} e_b^i$, and $D_a E_i^a = 0$, we have

$$G_i = i \sqrt{\text{det}(q)} \varepsilon_{ijk} e^b_k e^a_j K_{ab} = -i \varepsilon^{abc} K_{ab} e^i_c$$

and thus we conclude

$$\int d^3x \ p^{ab} \mathcal{L}_N q_{ab} = -2 \int d^3x \frac{1}{\sqrt{\text{det}(q)}} K_{(ab)} \mathcal{L}_N (E_i^q) E_i^b$$

$$= -2 \int d^3x \ [K_{ab} - K_{(ab)}] \mathcal{L}_N (E_i^q) e_i^b$$

$$= -2 \int d^3x \ [K^i_a - \frac{1}{2} \varepsilon^d_{abc} \varepsilon_{d,e} e^j_k] \mathcal{L}_N (E_i^q)$$

$$= -2 \int d^3x \ [K^i_a - \frac{1}{2} \varepsilon^j_{ijk} E_k^b G_j] \mathcal{L}_N (E_i^q)$$

$$= 2i \int d^3x \ [K^i_a \mathcal{L}_N (E_i^q) + \frac{1}{2} (\varepsilon^j_{ijk} \mathcal{L}_N (E_j^q) E_k^b) G_i]$$

(4.26)

which is precisely (4.14).

We finally come to the discussion of energy. Again we follow the strategy of taking the old ADM expression (2.11), write it in terms of Ashtekar’s variables, and look for the necessary modifications. Writing the Ashtekar connection in terms of the spin connection and the extrinsic curvature, it is easy to show that (cf [1]) the ADM scalar constraint turns out to be

$$C[N] = \int d^3x \ N [F_{ab}^i \varepsilon_{ijk} E_j^q E_k^b + 2D_a (E_i^q G_i)]$$

$$= \int d^3x \ N [F_{ab}^i \varepsilon_{ijk} E_j^q E_k^b + 2\overline{D}_a (E_i^q G_i)]$$

(4.28)

(we have used the fact that the divergence of a vector density is independent of the metric connection) and in [2] the necessary counter-terms are obtained simply by integrating this expression by parts an appropriate number of times in order to arrive at a manifestly finite expression. We follow this approach here.

We observe that the part proportional to $\overline{D}A$ in the first term and the second term in (4.28) are either $O(1/r^3)$ even or $O(1/r^2)$ odd, so they diverge while the remainder is already finite. We are now going to integrate by parts both divergent terms:

$$C[N] = \int d^3x \ [-2A^i_b \overline{D}_a (N \varepsilon_{ijk} E_j^q E_k^b) - 2E_i^q G_i D_a N + N A^i_a A^b_k \varepsilon_{ijk} E_m^q E_n^b e^{imn}]$$

$$= \int d^3x \ [-2(D_a N) E_i^q \overline{D}_b E^b_i + N ( -2A^i_b \varepsilon_{ijk} \overline{D}_a (E_j^q E_k^b) + A^i_a A^b_k \varepsilon_{ijk} E_m^q E_n^b e^{imn})]$$

(4.29)
where we have used the definition (4.1) of the Gauss constraint. While the term proportional to \( N \) in the volume integral is already manifestly convergent, the term proportional \( \overline{D}_b E^b \) is not. However, we write in the same term \( \overline{D}_b E^b = \overline{D}_b (E^b_i - \overline{E}^b_i) \) and integrate by parts again. Note that \( \overline{D}_b D_a N = (\det(q))^{-1/2} \overline{D}_a \overline{D}_b N + O(1/r^2) \) is of order \( O(1/r^2) \) at least, even for a boost \( \partial (x_{\text{cart}})^b / \partial \overline{x}^a \) is of order one and in the Cartesian frame \( (x_{\text{cart}})^a \) the assertion is obvious. We thus obtain

\[
C[N] = \int d^3 x \left[ -2 \overline{D}_b ((D_a N) E^a_i) (E^b_i - \overline{E}^b_i) + N (-2 A^i_b \epsilon_{ijk} \overline{D}_a (E^a_j E^b_k)) \right]
\]

\[+ \int_{\partial \Sigma} dS_a 2 [N E^a_i \overline{D}_b E^b \overline{D}_a (E^a_i - \overline{E}^a_i)] \]

and now the volume integral is manifestly convergent, and thus gives rise to the ansatz for the correct symmetry generator:

\[
[N] := C[N] - \int_{\partial \Sigma} dS_a 2 [N E^a_i \overline{D}_b E^b \overline{D}_a (E^a_i - \overline{E}^a_i)].
\] (4.31)

In fact, it is easy to prove that (4.31) is already differentiable. The boundary contribution of the volume term is given by

\[
\delta C[N]_{\text{boundary term}} = 2 \int_{\partial \Sigma} dS_a N \epsilon_{ijk} E^a_j E^b_k \delta A^i_b + \delta (E^a_i \overline{G}_i)
\]

\[= 2 \int_{\partial \Sigma} dS_a [N E^a_i \overline{D}_b E^b \overline{D}_a (E^a_i - \overline{E}^a_i)]
\]

where we could neglect all terms that are of order \( O(1/r^2) \) (in particular we could replace \( \overline{D} \) by \( D \)). Hence we have for the variation of the surface integral in (4.31)

\[
- \delta C[N]_{\text{boundary term}} = 2 \int_{\partial \Sigma} dS_a [N \delta E^a_i \overline{D}_b E^b - (D_b N) \delta E^b_i (E^a_i - \overline{E}^a_i)]
\] (4.34)

and the integrand of the latter integral is easily seen to be of order \( O(1/r^2) \) even or \( O(1/r^3) \) odd, and thus vanishes identically.

This completes the proof that expression (4.31) is differentiable.

Let us check that the boundary term in (4.31) is indeed the expression (2.11) given in section 2. We have

\[
E^a_i \overline{D}_b E^b_i = \sqrt{\det(q)} e^a_i \overline{D}_b \left( \sqrt{\det(q)} e^b_i \right)
\]
\[ \det(q)(E_i^a \overline{D}_b e^b + \frac{1}{2} q^{ab} q^{cd} \overline{D}_b q_{cd}) \]
\[ = \det(q) q^{ac}(e^b_c \overline{D}_b e^b + \frac{1}{2} q^{bd} \overline{D}_c q_{bd}) \]
\[ = \det(q) q^{ac} q^{bd}(- e^b_d \overline{D}_b e^d_c + \frac{1}{2} \overline{D}_c q_{bd}) \] (4.35)

whence (remember that \( N \sqrt{\det(q)} = N \) is the lapse), by using the the Gauss constraint,
\[ - \int_{\partial \Sigma} dS_a 2 N A^a_{eb} e^e_{ik} e^e_{ki} E^b_k \approx - \int_{\partial \Sigma} dS_a 2 N E^a_{eb} \overline{D}_b E^b \]
\[ = \int_{\partial \Sigma} dS_d N \sqrt{\det(q)} q^{ac} q^{bd} (2 e^d_i \overline{D}_c e^b_i - \overline{D}_c q_{bd}) \]
\[ = \int_{\partial \Sigma} dS_d N \sqrt{\det(q)} q^{ac} q^{bd} ([\overline{D}_c q_{ab} - \overline{D}_c q_{bd}] + 2 e^d_i [\overline{D}_c |e_i^d|] e^d_i) \]
\[ = E + \int_{\partial \Sigma} dS_d \sqrt{\det(q)} q^{ac} q^{bd} 2 e^d_i [\overline{D}_c |e_i^d|] e^d_i \] (4.36)

and the integrand of the second term in (4.36) can be shown to vanish to second order in \( 1/r \) by virtue of the symmetry of \( f_{ab} \) (recall (2.1)):
\[ e^d_i [\overline{D}_c |e_i^d|] e^d_i = \left( \tilde{e}_i^d + \frac{f_i^d}{r} + O\left( \frac{1}{r^2} \right) \right) \left( \overline{D}_c |e_i^d| + O\left( \frac{1}{r^3} \right) \right) \]
\[ = \tilde{e}_i^d \left( \frac{\tilde{e}_i^d}{2r} + \frac{f_i^d}{2r} \overline{D}_c e^d_i \right) + O\left( \frac{1}{r^3} \right) \]
\[ = \tilde{e}_i^d \overline{D}_c \frac{f_i^d}{2r} + O\left( \frac{1}{r^3} \right) \]
\[ = \overline{D}_c \frac{f_i^d}{2r} + O\left( \frac{1}{r^3} \right) \] (4.37)

since \( \overline{D}_c q_{ab} = \overline{D}_c \tilde{e}_i^d = 0 \). Hence we have already reproduced the ADM energy.

As far as the second contribution in (4.31) is concerned, we first note that the \( O(1) \) contribution is odd and thus integrates to zero. Hence we may replace any quantity of the integrand by another term which differs from the original one by a term which is higher by one order of \( 1/r \). We thus write, with first a glimpse at (2.11)
\[ \int_{\partial \Sigma} dS_a 2(D_b N) E^a_i (E_i^a - \tilde{e}_i^a) = \int_{\partial \Sigma} dS_a 2(D_b N) \]
\[ e^b_i \left( e^a_i - \sqrt{\frac{\det(q)}{\det(\tilde{q})}} \tilde{e}_i^a \right) = \int_{\partial \Sigma} dS_a 2(D_b N) \left( q^{ab} - \sqrt{\frac{\det(q)}{\det(\tilde{q})}} e^b_i e^a_i \right) \] (4.38)

and we expand the second term in (4.38) according to (3.1):
\[ \sqrt{\frac{\det(q)}{\det(\tilde{q})}} e^b_i \tilde{e}_i^a = \left( \frac{1}{\det(\tilde{q})} \right) \left( \tilde{e}_i^a - \frac{\tilde{e}_i^a f^b_c}{2r} \right) \tilde{e}_i^a + O\left( \frac{1}{r^3} \right) \]
\[ = \left( 1 - \frac{\tilde{e}_i^a f^b_c}{2r} \right) \left( \tilde{e}_i^a - \frac{\tilde{e}_i^a f^b_c}{2r} \tilde{e}_i^a \right) + O\left( \frac{1}{r^3} \right) \]
\[ = \tilde{e}_i^a - \frac{1}{2r} \left( q^{ac} q^{bd} + q^{ab} q^{cd} \right) f_{cd} + O\left( \frac{1}{r^2} \right) \] (4.39)
Generalized boundary conditions in terms of Ashtekar variables

Now, using that \( f_{cd} = r(q_{cd} - \tilde{q}_{cd}) + O(1/r) \), we find that \((4.38)\) can indeed be written

\[
\int_{\Sigma} dS_a \left( D_b N \right) (q_{ac} q_{bd} - q_{ab} q_{cd}) \frac{f_{cd}}{r} 
= \int_{\Sigma} dS_d \left( D_c N \right) (q_{db} q_{ca} - q_{dc} q_{ba}) \frac{f_{ba}}{r} 
= \int_{\Sigma} dS_d \left( D_c N \right) q_{ab} q_{cd} (q_{a|b} - \tilde{q}_{a|b}) D_d N
\]

\[(4.40)\]

and we recover exactly \((2.11)\).

Hence we succeeded in giving a differentiable and finite expression which reproduces the surface terms of the old ADM theory.

5. The symmetry algebra

We finally come to compute the Poisson structure of the generators \((4.1)\), \((4.14)\) and \((4.31)\).

The Poisson structure for Lagrange multipliers \(\Lambda^i, N^a\) and \(N\) corresponding to pure gauge transformations and translations has already been given in \([1]\).

As in \([2]\), it turns out that even for Lagrange multipliers corresponding to symmetries the symmetry algebra just equals the gauge algebra.

Since the transition from the ADM variables to the new variables is a canonical transformation, we can copy from \([2]\) the algebra restricted to the vector- and scalar constraint, because in section 4 we have shown that our expressions reduce exactly to the ADM expressions according to this canonical transformation. The only new brackets are those including a Gauss constraint. Let us display the complete variation of the symmetry generators:

\[
\delta \mathcal{G}_i[\Lambda^i] = \int_{\Sigma} d^3x \left[ (-\overline{D}_a \Lambda^i + \epsilon_{ijk} \Lambda^j A_b^k) \delta E^q_i - \epsilon_{ijk} \Lambda^j E^q_k \right] \delta A^i_a 
\]

\[
\delta H_a[N^a] = \int_{\Sigma} d^3x \left[ \left( \mathcal{L}_{\overline{R}} A^i_a + \mathcal{L}_{\overline{R}} (\epsilon_{ijk} E^i_a G^j_k - (G_i) \epsilon_{ijk} (\mathcal{L}_{\overline{R}} E^b_j E^k_a) E^k_b 
- (-\overline{D}_a \Lambda[N_i] + \epsilon_{ijk} \Lambda[N_i] A_b^k) \delta E^q_i - (\mathcal{L}_{\overline{R}} E^q_i + \epsilon_{ijk} \Lambda[N_i] E^q_k) \delta A^i_a \right) \right]
\]

\[
\delta H[N] = \int_{\Sigma} d^3x \left[ 2(\overline{D}_a (N \epsilon_{ijk} F^j_e E^k_b) + \epsilon_{ijk} \Lambda[N_i] E^q_i) \delta A^i_a 
- 2(N \epsilon_{ijk} F^j_e E^k_b + (\overline{D}_a N) G_i + (-\overline{D}_a \Lambda[N_i] + \epsilon_{ijk} \Lambda[N_i] A_b^k) \delta E^q_i \right]
\]

where we have defined

\[
\Lambda[N]^i_j := \frac{1}{2} \epsilon_{ijk} (\mathcal{L}_{\overline{R}} E^q_k) E^k_i \quad \Lambda[N_i]^j := -2(D_a N) E^q_i.
\]

Then it may be checked by explicit calculation that

\[
\{G_i[\Lambda^i], G_j[\Xi^j]\} = -i G_i[\epsilon_{ijk} \Lambda^j \Xi^k]
\]

\[
\{G_i[\Lambda^i], H_a[N^a]\} = 0 \quad \{G_i[\Lambda^i], H[N]\} = 0
\]

\[
\{H_a[M^a], H_b[N^b]\} = i H_a[(\mathcal{L}_{\overline{R}} N)^a] 
\]

\[
\{H_a[M^a], H[N]\} = -i H[(E^q_i E^k_b (\overline{M} D_b N - N D_b M))]
\]

\[(5.3)\]
according to the rule
\[ \{ A_a^i(x), E_b^j(y) \} = i \delta_b^a \delta_j^i \delta(x, y) \quad \{ A_a^i(x), A_b^j(y) \} = \{ E_a^i(x), E_b^j(y) \} = 0. \] (5.4)

These equations mean the following (see [2]): let
\[ \Phi[N] := \mathcal{G}_i[N^i] + H_a[N^a] + H[N] \] (5.5)
and compute the Poisson bracket \( \{ \Phi[M], \Phi[N] \} \) according to (5.4). Then we have the following combinations (the Lagrange multiplier of the Gauss constraint is always pure gauge, i.e. \( O(1/r^2) \) even):

1. \( M \) and \( N \) are both pure gauge (odd super-translations). Then \( \mathcal{L}_a \tilde{N}, M^a D_a \tilde{N} \) and \( E^a_i E^b_j M D_b \tilde{N} \) are again pure gauge, while \( M^i N^j \) is again of even parity when \( M^i, N^j \) are, so the gauge algebra closes, and we have a first class system.

2. \( M \) a symmetry, \( N \) pure gauge.
   Case (a). \( M \) a translation. Then \( \mathcal{L}_a \tilde{N}, M^a D_a \tilde{N} \) and \( E^a_i E^b_j M D_b \tilde{N} \) (and their counterparts obtained by interchanging \( M \) and \( N \)) are \( O(1/r) \) even, so the surface integrals vanish identically.
   Case (b). \( M \) a Lorentz rotation. Then \( \mathcal{L}_a \tilde{N}, M^a D_a \tilde{N} \) and \( E^a_i E^b_j M D_b \tilde{N} \) etc are \( O(1) \) odd, and thus the surface integrals also vanish identically.
   This means that the Poisson generators have weakly vanishing brackets with the gauge generators, i.e. they are observables in the sense of Dirac.

3. \( M \) and \( N \) are both symmetries. Then \( \mathcal{L}_a \tilde{N}, M^a D_a \tilde{N} \) and \( E^a_i E^b_j M D_b \tilde{N} \) etc display the Poisson algebra.
   Accordingly, we have managed to reproduce the results of [2] in the new variables.

Acknowledgments

I thank Professor A Ashtekar for telling me why the surface term in (4.14) without the spin connection coincides with (4.14) for translations. This project was supported by the Graduiertenkolleg of the Deutsche Forschungsgemeinschaft.
