Introduction
Thyroid ectopia (TE) is an embryological aberration of thyroid migration characterized by presence of thyroid tissue at sites other than its normal location, most commonly in the lingual region (90%; incidence 1:4000-1:10000), followed by the sublingual, hyoid/pre-laryngeal, and mediastinal regions (1,2). Other rare sites include the pharynx, oesophagus, trachea, lung, heart, breast, duodenum, mesentery, and adrenal gland (1,2,3). Observed most commonly in children and adolescents (male/female=4/1), TE is usually functionally incapable of meeting physiologic requirements resulting in hypothyroidism in 33-62% of these individuals (4). TE in the lingual, sublingual or laryngeal region may present with localized swelling and compressive symptoms resulting in dysphagia, dysphonia, and dyspnea often necessitating surgical removal which is frequently complicated by difficult intubation and increased peri-operative bleeding (5). We present three cases of TE with compressive symptoms all managed conservatively with favorable outcomes.

Case 1
An 8-year-old boy (height 122 cm; 25-50th percentile; weight 20.5 kg; 25-50th percentile) presented with snoring which had started at age 5 years and had increased over time. Complaints of dysphagia and odynophagia had started six months ago, at which time the patient was detected to have a mass (3X2 cm reddish swelling with smooth surface; Figure 1a) at the base of his tongue, demonstrating an increased uptake on 99mTc scan and being consistent with lingual thyroid. No uptake was noted in the thyroid bed (Figure 1b). Ultrasonography (USG) of the neck...
revealed absence of thyroid tissue in the normal position in the neck and confirmed the presence of lingual thyroid. Hormonal evaluation revealed a state of subclinical hypothyroidism (Table 1). Levothyroxine, administered in a dose of 75mcg/d for one year, resulted in reduction of the swelling along with resolution of the dysphagia and odynophagia (Figure 1c). Levothyroxine was continued in a dose of 50mcg/d.

**Case 2**

An 18-month-old girl patient (height 70 cm; 5-10th percentile; weight 9.5 kg; 10-25th percentile) presented with complaints of poor feeding and of a swelling in the submandibular region, which moved with deglutition, noted 6 months ago (Figure 2a). The swelling was detected to be a 4X3 cm mass at the base of the tongue which showed increased uptake on $^{99m}$Tc scan, consistent with lingual thyroid, without any uptake in thyroid bed (Figure 2b). The patient was also shown to have primary hypothyroidism (Table 1). Following one year of levothyroxine therapy at 50mcg/d led to resolution of feeding problems along with a decrease in the size of the swelling.

**Case 3**

Primary hypothyroidism was diagnosed in a 5.5-year-old girl patient (height 105 cm; 25th percentile; weight 17 kg; 25-50th percentile) who presented with complaints of dysphagia, poor feeding, constipation, and dry skin in the past six months and a midline neck swelling moving with deglutition noted at age 3 years (Figure 3a). The patient had an increased $^{99m}$Tc uptake suggestive of functional thyroid tissue in a thyroglossal cyst. A second area of uptake was noted in the submandibular region along with normal uptake in the thyroid bed (Figure 3b). These findings were confirmed by USG (Table 1). A diagnosis of dual ectopic thyroid (thyroglossal cyst and submandibular region) with eutopic thyroid was made. Symptoms subsided and dysphagia resolved with levothyroxine given in a dose of 50mcg/d and increased to 75mcg/d over nine months.

Discussion

Aberrant descent of thyroid anlage from the floor of the primitive hypopharynx is the cause for TE and the associated absence of eutopic thyroid in ~70% of the cases (6,7,8). In our series of three patients, eutopic thyroid was present in only one case. Lingual thyroid was documented in two patients, and oral examination played an important role in its diagnosis. Any patient with a midline swelling in the head and neck region, below the base of tongue should undergo thyroid scintigraphy to rule out TE. Thyroglossal cysts, which are remnants of the thyroglossal duct are the most common midline neck mass in childhood (>75%) with 35-70% containing thyroid tissue (9,10). Hence, thyroid scintigraphy is mandatory in the evaluation of a thyroglossal cyst, especially when solid tissue is palpable or documented on imaging. Malignancy is rare in thyroglossal cysts (found in <1% cases) and is almost always papillary carcinoma (11).

Computed tomography (CT) and magnetic resonance imaging (MRI) are helpful in better anatomic delineation of the lesion, however are not routinely required for diagnosis since the same information can be obtained by clinical examination, thyroid scintigraphy and USG. Use of CT/MRI may be limited to difficult cases where surgical removal is contemplated.

Presence of two ectopic foci of thyroid tissue in the same patient (dual ectopia) is extremely rare with only a few isolated reports (12,13). In most patients of dual ectopia, one of the foci is usually lingual/sublingual thyroid and the other is subhyoid/suprahyoid thyroid (12,13). Presence of dual ectopia along with a eutopic thyroid as observed in Case 3 is even rarer, with perhaps only a single report to date (8).

TE carries a low risk of malignancy (<1%) and this is a point in favor of conservative management (8,14). Levothyroxine treatment is usually warranted for several months before contemplating for alternatives. $^{131}$I ablation is increasingly
being shown to have a beneficial role in managing compressive symptoms of TE in hyperthyroid, euthyroid, and hypothyroid individuals (15,16). Limitations of $^{131}$I therapy include the need for high doses to induce regression (~20 mCi or more), especially in euthyroid and hypothyroid individuals. $^{131}$I therapy is generally avoided in children and young adults due to its potential unknown long-term effects (15,16,17). Surgery should be reserved for patients not responding to levothyroxine treatment and those presenting with severe compressive/obstructive symptoms or bleeding.

To conclude, it may be said that levothyroxine supplementation has an important role in managing TE, not only in treating hypothyroidism but also in resolution of its compressive symptoms by reducing the size of the ectopic gland.
