Received: 14 October 2013 / Revised: 10 March 2014 / Accepted: 13 March 2014 / Published online: 12 September 2014 © The Author(s) 2014. This article is published with open access at Springerlink.com

Abstract The authors proposed an integrated gasification fuel cell zero-emission system. The coal char gasification is discussed using high temperature and concentration of CO₂ produced by solid oxide fuel cells and oxy-fuel combustion. The gasification is simulated by Aspen plus based on Gibbs free energy minimization method. Gasification model of pulverized coal char is computed and analyzed. Effects of gas flow rate, pressure, preheating temperature, heat losses on syngas composition, reaction temperature, lower heating value and carbon conversion are studied. Results and parameters are determined as following. The optimum O₂ flow rate is 20 kg/h. The reaction temperature decreases from 1645 to 1329 °C when the CO₂ flow rate increases from 0 to 5 kg/h, the CO₂ flow rate should be operated reasonably; lower heating value reduces and reaction temperature increases as the pressure increases; compared to the CO₂ preheating, O₂ preheating has greater influence on reaction temperature and lower heating value.

Keywords Coal char · Gasification · Aspen plus

1 Introduction

In recent years, global demand for fossil energy has been growing rapidly with the economic and social development of the world. Long-term use of fossil energy has led to serious environmental problems. Especially the green house effect is getting worse because of CO₂ emission, which has attracted worldwide concerns (Gleick et al. 2010; Mao 2010; Wei et al. 2011). Chinese government has proposed that by the year 2020, CO₂ emission of unit GDP could be reduced by 40 % to 45 % compared with the emission in 2005. As a result, CO₂ emission reduction and development of low carbon science and technology have become the most urgent scientific issues to solve for the world (Xie H 2010; Xie et al. 2012).

Coal production in China was 3.66 billion tons in 2012, increased by 4 % than in 2011. Coal utilization is the main source of CO₂ emission. The percentage of CO₂ emission produced by coal utilization is as high as 70 % (Huang 2012; Sun and Gao 2013). Clean and effective utilization of coal is the key to achieve sustainable development of energy for the world, especially for China. Coal gasification is the core technology in fuel cells, coal chemical synthesis, IGCC, and coal gasification-based poly-generation. It is the most efficient way to achieve clean and effective utilization of coal.

CO₂ can be used as gasification agent to gasify coal char. Then high purity CO can be used for chemical synthesis and Solid Oxide Fuel Cells (SOFCs), which can realize clean and effective utilization of coal (Peng and Han 2009).

Coal gasification in CO₂ rich gas atmosphere is recognized as one of the most promising technology for controlling CO₂ emission in pulverized coal-fired power plants. This technology has been reviewed (Antonio and Mara 2004). Large amount of syngas, mainly CO, can be produced by this technology. Syngas production from coal gasification under O₂/CO₂ atmosphere has been simulated using CFD software Fluent. A 3D geometry simulation
model for gasification was established. The results show that the gas temperature decreases and the gross heating value of syngas increases with the increasing of CO$_2$ concentration; besides, effect of particle size on coal gasification is significant (Alam et al. 2012). Gasification of aquatic biomass under O$_2$/CO$_2$ atmosphere has been carried out. Effects of O$_2$, CO$_2$ concentrations, feeding rate and [H$_2$O]/[C] ratio on O$_2$/CO$_2$ gasification behavior have been reported (Toshiaki et al. 2009; Toshiaki et al. 2013).

The syngas produced by coal gasification can be used for SOFCs. Then high temperature and concentration of CO$_2$ is produced after electrochemical reaction. The CO$_2$ could be used for gasification of char. For this closed cycle system, vast heat of exhaust could be used efficiently and energy needed in the gasification could be reduced. Also the system can realize CO$_2$ emission reduction and even zero emission. The specific principle is shown in Fig. 1. O$_2$ can be separated from air by oxygen transportation Membrane (OTM), which is prepared by perovskite powders and operated at high temperature from 800 to 1000 °C. Then high temperature O$_2$ is produced.

The process flowsheet simulation program Aspen plus is used in this paper. The simulation is based on entrained-flow gasifier. The physical property databases and unit module in Aspen plus have also been used in the simulation model. Coal char gasification model under O$_2$/CO$_2$ has been established, which can provide theory bases for the determination of process conditions.

2 Establishment of simulation model

As shown in Fig. 2, the simulation model consists of three unit modules, five material streams and two heat streams. They are the unit module of RYIELD, RGIBBS, SSPLIT; material streams of NATCOKE (coal char), CO$_2$, O$_2$, SYNGAS and ash; heat streams of QLOSE (heat loss of the gasifier) and QDECOMP (Heat of char cracking). The reaction blocks used are the RYIELD, RGIBBS and SSPLIT. Nonconventional material of coal char can crack to single element molecule in the RYIELD reactor and the cracking heat can be led into the RGIBBS reactor.

3 Results and discussion

3.1 Effect of O$_2$ flow rate on the gasification

The computation in the RGIBBS reactor is based on Gibbs free energy minimization method. SSPLIT module is used to simulate the separation of syngas and ash. The model is established under the assumptions that the gasifier runs

![Fig. 1 Closed cycle system of CO$_2$ gasification of coal char](image1)

![Fig. 2 Diagram of Aspen plus model](image2)
stably, no operating parameters change, the gasification agent and coal char particle can mix completely instantly, the elements hydrogen, oxygen, nitrogen and sulfur convert to gas phase totally except element carbon. There is no pressure drop in the gasifier, ash in the coal char is inert material that does not take part in gasification reaction, temperature distribution in coal particle is uniform, all the gas-state reactions are fast and attain equilibrium (Wang et al. 2004; Zhou et al. 2010).

Coal char used in this paper is from Xuzhou, China (Lin and Zhao 2012). The proximate analysis, ultimate analysis and sulfur analysis are shown in Table 1. \( \text{O}_2 \) and \( \text{CO}_2 \) are chosen as gasification agents. The handling capacity of coal char is 21.59 kg/h (The mass flow rates are set according to simulation requirement). Gasification pressure is 3 MPa when it keeps steady. Mass ratio of \( \text{O}_2 \), \( \text{CO}_2 \) to coal char is the key factor to the quality of syngas.

Other parameters keep steadily. The coal char and \( \text{CO}_2 \) mass flow rate are 21.59 and 2.16 kg/h respectively. The relationships among syngas composition, reaction temperature, lower heating value of syngas and \( \text{O}_2 \) content are shown in Fig. 3. The reaction temperature increases rapidly with the rising of \( \text{O}_2 \) content because of the increased combustion reaction. At the start of gasification there is not enough \( \text{O}_2 \), so imperfect combustion of char occupies a predominant position. As a result, molar ratio of CO increases gradually at first. Then the molar fraction of CO decreases because the complete combustion reaction increases as a result of more \( \text{O}_2 \) being injected into the gasifier. Combustion reactions of \( \text{H}_2 \) and CO increase with the rising of \( \text{O}_2 \) content, which leads to higher \( \text{H}_2\text{O} \) and \( \text{CO}_2 \) content.

As shown in Fig. 3 the concentration of CO increases with the increasing of \( \text{O}_2 \) flow rate, and then decreases. Although the concentration of \( \text{H}_2 \) decreases gradually, it is much lower than CO’s. As a result, the concentration of CO is the leading factor, which promotes lower heating value and the lower heating value of syngas increasing to the maximum value and then decreasing with increasing of \( \text{O}_2 \) mass flow rate.

### 3.2 Effect of \( \text{CO}_2 \) flow rate on the gasification

As illustrated in Fig. 4 the reaction temperature decreases gradually with the increasing of \( \text{CO}_2 \) flow rate when the coal char and \( \text{O}_2 \) mass flow rates are 21.59 and 17.57 kg/h.
respectively. It decreases from 1645 °C to 1329 °C when CO₂ flow rate increases from 0 to 5 kg/h. Reaction temperature decreasing is caused by several factors listed below. First, diffusion rate of O₂ in the CO₂ atmosphere is slower with the increasing of CO₂ flow rate, which leads to slower combustion reaction. Second, the larger heat capacity of CO₂, increasing of CO₂ flow rate and keeping O₂ flow rate steady, leads to lower reaction temperature. Third, the Boudouard reaction rate is enhanced with the increasing of CO₂ flow rate and more heat is consumed, which leads to lower reaction temperature.

Reaction temperature decreasing is not favorable to Boudouard reaction. However, the increasing of CO₂ concentration promotes Boudouard reaction and its effect on Boudouard reaction is more dominant than the temperature. As a result, the molar ratio of CO increases with the rising of CO₂ flow rate. Reaction of coal char with H₂O is endothermic. Temperature decreasing is not favorable to the reaction. Temperature decreasing is good for water gas shift reaction and the production of CO₂ and H₂, but the concentrations of CO₂ and H₂ are very low. Therefore, the reaction of coal char with H₂O is more dominant in the production of H₂. As shown in Fig. 4, the concentration of H₂ decreases with the increasing of CO₂.

The reverse water gas shift reaction increases as a result of increasing of CO₂ and partly H₂ converts to H₂O. As a result, the lower heating value of syngas decreases slightly with the increasing of CO₂ mass flow rate as shown in the Fig. 4.

3.3 Effect of pressure on the gasification

The relationship of the pressure with gasification is shown in Fig. 5 when the coal char, O₂ and CO₂ mass flow rate are 21.59, 17.57 and 2.16 kg/h respectively. The reverse Boudouard reaction rate increases with the rising of pressure, which leads to slightly decreasing of CO molar ratio and increasing of heat and CO₂ content. The reaction temperature is high enough and the effect of pressure is not remarkable, but pressurizing can increase syngas production per unit time and production capacity. CO₂ content increasing is favorable to the reverse water gas shift reaction and the molar ratio of H₂ decreases. As a result, the lower heating value decreases slightly.

3.4 Effect of preheating temperature on the gasification

Effect of preheating temperature on the gasification with coal char, O₂ and CO₂ mass flow rates are 21.59, 17.57 and 2.16 kg/h is shown in Fig. 6. The preheating of O₂ and CO₂ can increase the reaction temperature and the lower heating value, but the effect of CO₂ preheating on reaction temperature and lower heating value is weaker than the O₂ preheating. The reaction temperature and the heating value increase by only 25 °C and 0.0063 MJ/M³ respectively, when the preheating temperature of CO₂ increases from 300 to 1000 °C. However, the heat capacity of CO₂ is so high that it is unnecessary for high preheating temperature.

3.5 Effect of reaction temperature on the gasification

To obtain the effect of temperature on gasification, heat loss of gasifier is introduced in the gasification. The gasifier
heat loss is the ratio of heat loss of the gasifier with heating value of coal. As coal char, O\textsubscript{2} and CO\textsubscript{2} mass flow rates are 21.59, 17.57 and 2.16 kg/h separately, the relationships between syngas composition, temperature, lower heating value and gasifier heat loss are illustrated in Fig. 7. Reaction temperature decreases as the heat loss increases from 0 % to 2 %, which leads to slower Boudouard reaction rate and lower molar fraction of CO. The H\textsubscript{2} content decreases because of the decreasing temperature and the reaction rate of char with H\textsubscript{2}O.

---

**Notes**

O\textsubscript{2} preheating temperature is much high because the O\textsubscript{2} is separated by OTM which is operated about 800 to 1000 °C.

---

Fig. 5 Effect of pressure on syngas composition, reaction temperature and lower heating value of syngas (MJ/m\textsuperscript{3})

Fig. 6 Effect of preheating temperature on reaction temperature and lower heating value of syngas (MJ/m\textsuperscript{3})
3.6 Effects of different factors on the carbon conversion

Effects of $\text{O}_2$ and $\text{CO}_2$ mass flow rates, pressure, preheating temperature and heat loss on the carbon conversion were simulated. The results are shown in Table 2.

Carbon conversion increases with increasing of $\text{O}_2$ and $\text{CO}_2$ mass flow rates. Carbon combustion reactions are enhanced with the increasing of $\text{O}_2$ mass flow rates so carbon conversion increases greatly. We can get that the optimum $\text{O}_2$ mass flow rate is 20 kg/h for syngas heating value in Fig. 3. Increasing of $\text{CO}_2$ mass flow rates is good for Boudouard reaction and carbon conversion. Pressure, preheating and gasifier heat loss have also some effects on carbon conversion, but they are not apparent.

4 Conclusions

The coal char gasification using $\text{O}_2$/CO$_2$ based on IGFC was proposed. The thermodynamic analysis of the gasification under $\text{O}_2$/$\text{CO}_2$ atmosphere was studied using Aspen plus simulation method. The results are concluded as following.

1. The molar ratio of CO increased gradually when the $\text{O}_2$ flow rate is lower than 20 kg/h. Then the molar fraction of CO decreases. H$_2$ molar ratio decreases gradually with the increasing of $\text{O}_2$ mass flow rate. The optimum lower heating value is obtained when the $\text{O}_2$ flow rate is 20 kg/h.

2. The Mass flow rates of $\text{CO}_2$ has a significant effect on reaction temperature. The reaction temperature decreases from 1645 to 1329 °C when $\text{CO}_2$ flow rates increases from 0 to 5 kg/h because of the slower diffusion of $\text{O}_2$ in $\text{CO}_2$ atmosphere, larger heat loss.

### Table 2: Effect of different factors on carbon conversion

|                      | O$_2$ mass flow rates (kg/h) | Carbon conversion | CO$_2$ mass flow rates (kg/h) | Carbon conversion | Pressure (bar) | Carbon conversion | O$_2$ preheating (°C) | Carbon conversion | CO$_2$ preheating (°C) | Carbon conversion | Heat loss of gasifier (%) | Carbon conversion |

|                      | 17.5                         | 0.8537            | 1.5                            | 0.8439            | 3             | 0.8591            | 400                    | 0.8554            | 1000                   | 0.8537            | 1.5                      | 0.8537            |
|                      | 20                           | 0.9657            | 2.16                           | 0.8538            | 4             | 0.8791            | 600                    | 0.8576            | 1000                   | 0.8563            | 0.5                      | 0.8563            |

Fig. 7 Effect of heat losses of gasifier on syngas composition, reaction temperature and lower heating value of syngas (MJ/m$^3$)
capacity of CO\textsubscript{2} and promoting of Boudouard reaction. The syngas lower heating value decreases gradually with the increasing of CO\textsubscript{2} mass flow rates.

(3) The heating value is lower with the raising of pressure, but pressurize is favorable to reaction temperature. The molar ratios of CO and H\textsubscript{2} decreased slightly even under high pressure because of the high reaction temperature.

(4) Preheating of O\textsubscript{2} and CO\textsubscript{2} can both enhance reaction temperature and syngas heating value, but effect of CO\textsubscript{2} preheating is weaker than O\textsubscript{2} preheating.

(5) The carbon conversion increases with the increasing of O\textsubscript{2}, CO\textsubscript{2} flow rates and O\textsubscript{2}, CO\textsubscript{2} preheating temperature. Pressure is not favorable to the carbon conversion because it could inhibit the Boudouard reaction. The gasifier heat loss can reduce reaction temperature and then the carbon conversion decreases.
