Abstract. Herein we report the successful implementation of the consecutive and simultaneous photodissociation with high (213 nm) and low (10.6 μm) energy photons (HiLoPD, high-low photodissociation) on ubiquitin in a Quadrupole-Orbitrap mass spectrometer. Absorption of high-energy UV photon is dispersed over the whole protein and stimulates extensive C-Cα backbone fragmentation while low-energy IR photons gradually increases the internal energy and thus preferentially dissociates the most labile amide (C-N) bonds. We noticed that simultaneous irradiation of UV and IR lasers on intact ubiquitin in a single MS/MS experiment provides a rich and well-balanced fragmentation array of a/x, b/y and z ions. Moreover, secondary fragmentation from a/x and z ions leads to the formation of satellite side-chain ions (d, v and w) and can help to distinguish isomeric residues in a protein. Implementation of high-low photodissociation in a high-resolution mass spectrometer may offer considerable benefits to promote a comprehensive portrait of protein characterization.

Keywords: Photodissociation; UVPD; IRMPD; Ubiquitin; Top-down Proteomics;
Introduction

Photon-based activation methods including ultraviolet photodissociation (UVPD) [1–3] and infrared multiphoton dissociation (IRMPD) [4–6] have received great attention as an alternative to electron-driven methods [7–11]. In recent years, UVPD has been implemented in high resolution mass spectrometry and employed for peptide and whole protein characterizations [12–19]. High energy UV photons preferentially cleave Cα–C bond in peptides and proteins producing abundant a/x ions. Other fragment ions such as c/z, and y ions are also detected in UVPD providing nearly complete sequence coverages [12, 20].

Contrasting to UVPD and electron transfer dissociation (ETD), multiple low energy IR photon excitation selectively breaks the most labile amide (C-N) bonds and generates b and y ions similar to the traditional slow-heating collision activation dissociation (CAD) method [21]. IRMPD has been implemented in different instruments including quadrupole ion traps [22] and dual pressure linear ion traps [6, 23, 24]. Vasicek et al reported the execution of IRMPD in the HCD (High Collision Dissociation) cell of a modified hybrid linear ion trap-Orbitrap mass spectrometer [25].

The dissociation mechanisms involved after high and low energy photon excitation are quite different. Absorption of a single high energy photon (in the UV) is sufficient to induce dissociation of a peptide and protein in gas phase. On the other hand, multiple absorption of low energy photons (in the IR) are required before fragmentation. Excitation is followed by fast internal vibrational redistribution (IVR) and causes a slow and steady rise of the internal energy until it exceeds the dissociation threshold and thus induces cleavage of the labile bonds [2].

Despite some analytical challenges, coupling of high and low energy activation pathways in a single MS/MS event is expected to offer diverse fragmentation arrays and thus deliver improved,
efficient, and well-balanced fragmentation for whole protein characterization. Tsybin et al reported the implementation of IRMPD with electron capture dissociation (ECD) in FT-ICR mass spectrometer [26]. Electron and photon irradiation significantly improved the formation of sequence ions for peptides and proteins. Simultaneous IR photoactivation with ETD, known as activated ion electron transfer dissociation (AI–ETD), is also implemented in an ion trap-Orbitrap Elite system [27]. Moreover, tandem ETD spectra exhibited abundant peaks related to unreacted and charge reduced precursors. Hybrid AI-ETD showed better performance for lower charge states and produce specific fragment ions. The combination of UVPD with ETD (known as ETUVPD) in an ion trap-Orbitrap has also been reported [28]. The combined ETUVPD method showed balanced fragment ions with increased number of c and z ions. The fragmentation efficiency of ETD can also be enhanced by other means such as additional activation with CID and HCD, known as ETciD and EThcd [29,30]. These hybrid methods showed rich fragmentation spectra compared to CID, HCD and ETD alone.

Although a few studies are coupling electron and photon based methods, integrating electron-driven technique with low or high collision activation approaches, so far there is no study reporting the combination of high and low energy photons for characterizing protein within a single MS/MS framework. Here, we report the implementation of a method combining solid-state 5th harmonic 213 nm laser excitation with 10.6 μm CO₂ laser excitation in hybrid quadrupole-Orbitrap mass spectrometer using different excitation schemes (consecutive IR+UV, UV+IR and simultaneous UV/IR) for top-down characterization of ubiquitin. This high-low energy photon based method (HiLoPD) improves the fragmentation pattern providing well-proportioned a/x, b/y and z-ions with richness of secondary fragment ions including d, v and w.
Materials and Methods

Laser setup and experiments. A simple schematic presentation of the execution of combined IRMPD and UVPD irradiation in the HCD cell of a hybrid quadrupole-Orbitrap is presented in Figure 1. IRMPD experiments were performed using a 50 W cw-CO₂ laser (ULR-50, Universal Laser System®, Scottsdale, AZ). The wavelength of the CO₂ laser is 10.6 μm with a beam diameter and divergence (full angle) of 4±1 mm and 5±1 mrad, respectively. 60% of the nominal laser power was used. The IR beam is directed to the HCD cell using gold mirrors. The IR beam was gated on an external TTL signal. Irradiation times from 0.1 to 1 s were tested. The N₂ pressure in the HCD cell was adjusted to optimize the IR fragmentation while avoiding significant loss of signal (pressure controller set to ~0.09 MPa). For the UVPD experiments, the fifth harmonic (λ=213 nm, ~1 mJ/pulse) of a 20 Hz BrillantB solid-state Nd:YAG laser (Quantel, Les Ulis, France) was used. A mechanical shutter (SH05/TSC001, Thorslab) was used to allow, on demand, the beam in the HCD cell. For UVPD, the optimal shutter open time was determined to be 0.2 s (4 laser shots) was determined. In order to combine both CO₂ and UV laser beams, a half-moon gold mirror was used on the IR beam path to the HCD cell. Also, a BaF₂ window (wavelength range 0.2-12 μm, Ø 25.4 mm, thickness 5 mm) was placed at the rear of the HCD cell, which transmit both IR (10.6 μm) and UV (213 nm) beams with 90 and 85% efficiency, respectively.

In order to irradiate ions only when they are in the HCD cell, the voltage on test-point 18 (TP18), located on Q-Exactive electronic board, was monitored. In our experimental conditions, the falling edge (-10 V → -350 V) on the TP18 is used to determine the moment when ions are ejected from the C-trap to the HCD-cell (see Figure S1). Two independent TTL pulses are then generated, with width and delay adjustable with regards to the TP18 trigger. The TTL pulses are used to lift the gate on the CO₂ laser and open the shutter on the UV beam path.
Three different coupling schemes between IR and UV were implemented (Figure S1). In scheme I, CO$_2$ laser was *ON* for 1 s and then followed by 4 UV pulses (0.2 s). In scheme II, 4 pulses of UV were admitted in the HCD cell first, and followed by 1 s of CO$_2$ laser. In those first two schemes, IR and UV were used consecutively: when CO$_2$ laser was *ON*, the UV laser was *OFF* and *vice versa*. In scheme III, the CO$_2$ laser was turned *ON* and the UV shutter was open concomitantly. As in previous schemes, IR was left *ON* for 1 s while the UV shutter was left open for 0.2 s (4 pulses). In each scheme, the coupled IR/UV irradiation takes place during single HCD events in MS$^2$ sequences.

**Mass Spectrometry.** All experiments were performed on a hybrid quadrupole-Orbitrap Q-Exactive® mass spectrometer (Thermo Fisher Scientific, San Jose, CA, USA) equipped with a HESI ion source. Ubiquitin (76 residues, 8.6 kDa) from bovine erythrocytes was obtained from Sigma-Aldrich and used without any further purification. Ubiquitin samples were prepared at 10 $\mu$M concentration in 50/49/1 (v/v/v) methanol/water/acetic acid and directly infused to MS at a flow rate of 5 $\mu$L/min. All mass spectra were acquired using a mass range of 200-2000 m/z and resolving power of 140000 at m/z 400. The AGC (Automatic Gain Control) target was set to 5x10$^6$ and the maximum injection time was set at 250 ms. The isolation width was 8-10 Th. To avoid collisions and CID contamination, HCD collision energy was set to the minimum 2 eV. All experiments were performed for 3 microscans and averaging for 50 scans.

**Data Analysis.** Raw files were deconvoluted and deisotoped to the neutral monoisotopic masses using Xtract algorithm provided by Thermo Scientific Inc. Manual analysis of IRMPD, UVPD, and combined UVPD and IRMPD data was performed with the aid of ProSight Light software [31] and Protein Prospector V5.14.4. ([http://prospector.ucsf.edu/prospector/mshome.htm](http://prospector.ucsf.edu/prospector/mshome.htm)). All major ion types (a, a+1, a+2, b-1, b, b+1, b+2, c-1, c, c+1, x-1, x, x+1, x+2, y, y-1, y-2, z-1, z, z+1) were
considered. We observed substantial number of secondary fragment ions including d, v and w which were analyzed by Protein Prospector. H₂O and NH₃ losses from the fragment ions were also considered. Single protein mode with a fragment mass tolerance set to 15 ppm was used for all methods.

Results and Discussion

Optimization of IRMPD on Intact Protein. The overall performance of IRMPD is hindered by the failure to provide adequate fragmentation of peptide or proteins at the standard pressure in the HCD cell. Although relatively high pressure is desirable for collision cooling during the ion accumulation to obtain maximum trapping efficiency, it is disadvantageous to ion activation and dissociation [32]. In the Q-Exactive mass spectrometer, the HCD cell and C-trap are filled with N₂ gas with chamber pressure of ~10⁻⁵ mbar known as High Vacuum (HV) region whereas Orbitrap kept the low pressure at ~10⁻¹⁰ mbar designated as Ultra High Vacuum (UHV) region. A pressure regulator allows control of the collision gas valve and hence the pressure in the HCD cell. The position of the pressure controller also has an effect on the High Vacuum pressure value. Here, where we discuss high and low pressure it is the HCD cell pressure governed by the pressure controller position and estimated via High Vacuum gauge that is being considered. A previous study on hybrid QLT-Orbitrap indicated that the level of the collision gas (N₂) must be lowered [33]. At high pressure in the chamber (HV ~4.6 x 10⁻⁵ mbar, pressure controller 0.5 MPa), there is no noticeable photodissociation observed for +12 charge state ion of ubiquitin even at longer (1 s) irradiation time (Figure 2). The collision frequency, which is associated with the collision cross-section [34] of the protein, of +12 charge state ion of ubiquitin is typically around 6700 s⁻¹ at high pressure of 10⁻⁴ mbar (Figure S2). This high collision rate promotes collision deactivation and
cooling of the protein before it can undergo fragmentation, resulting in limited photodissociation being observed. The fragmentation efficiency improves as the pressure is reduced. At low pressure (HV \(\sim 9.3 \times 10^{-6}\) mbar, pressure controller \(~0.09\) MPa), the dissociation efficiency is augmented significantly for +12 charged precursor ion of ubiquitin. At \(\sim 9.3 \times 10^{-6}\) mbar pressure, the collision frequency of +12 ion of ubiquitin is reduced. It is noticed that pressure lower than \(~0.09\) MPa on the pressure controller can lead to more fragment ions, however, the signal is not very stable at this range and moreover sensitivity and resolution are also decreased. The irradiation time also has a major impact on the photodissociation yield of ubiquitin (Figure S3). At lower pressure, when ubiquitin is irradiated for 0.1 s, the fragmentation efficiency is only about 25% which is considerably improved to 68% for 1 s irradiation time (Figure S4). Most previous studies related to IRMPD used a laser irradiation time less than 0.1 s in LIT [6, 27]. As is evident from other studies, higher laser power is required for superior fragmentation efficiency of larger peptides and intact proteins [6,35,33,36].

The IRMPD on the +12 charge state ion of ubiquitin identifies a total of 141 fragment ions of which 41 are b-type and 98 are y-type ions. Exact masses and assignments of the ions detected in the IRMPD of the 12+ precursor ion \((m/z=714.7279)\) of ubiquitin are summarized in Table S1. For this charge state, more than double the number of y-type ions are identified as compared to b-type ions. The sequence coverage for the +12 ion is 59% (44 bonds break) which is significantly higher than the coverage 24% (18 bonds break) reported earlier when IRMPD was first implemented in high resolution Orbitrap mass spectrometer (Figure S5) [25]. We notice that 60% of the nominal laser power with combination of lower pressure (HV \(\sim 9.3 \times 10^{-6}\) mbar) and longer irradiation time (~1 s) are optimal for characterization of intact protein by IRMPD in a quadrupole-Orbitrap system.
**UVPD, IRMPD and HiLoPD on Ubiquitin.** The photodissociation mass spectra using IRMPD, UVPD and combined IR and UV (scheme I, II, III) of the +13 precursor ion of ubiquitin are presented in Figure 3.

First of all, the +13 precursor ion of ubiquitin was subjected to UVPD only. All 213 nm UVPD experiments have been performed in the low pressure regime (~9.3 x 10^{-6} mbar) to make unbiased comparison with consecutive or simultaneous irradiation of IRMPD and UVPD. Even at low pressure, the 213 nm UVPD on the +13 charge state ion identifies a total of 209 fragment ions (Figure 4a) including 68 a-type, 5 b-type, and 10 c-type ions as well as 38 x-type, 59 y-type and 28 z-type ions (Table S2). Along with traditional a/x, y and c/z ions, a+1/x+1, x+2, y-1, y-2, c-1, and c+1 ions of ubiquitin are also detected. Recently, we reported that the radical-driven backbone fragmentation provides 22 distinctive fragment ion types for peptide anions at 213 nm UVPD [15].

High energy UVPD (157 and 193 nm) reported abundant formation of the radical a+1 and x+1 ions [37,38,39]. Here we observed the similar feature at 213 nm (5.8 eV) UVPD which produces significant number of a+1/x+1 ion. The mechanism of the homolytic cleavage of the Cα-C(O) bond which produces a+1/x+1 ions has been proposed elsewhere [15]. Moreover, the formation of y-1 and y-2 occur from the secondary dissociation of the x+1 radical and is associated with presence of proline residues [38,18]. Neutral losses of NH₃ are detected from a and y ions. The UVPD sequence coverage achieved for the +13 precursor ion is 76%.

The IRMPD experiment on the +13 ion of ubiquitin detects a total of 121 fragment ions (Figure 4a). Exact masses and assignments of ions detected in the IRMPD of the +13 ion (m/z=659.8249) of ubiquitin are summarized in Table S3. Among them, 49 ions are b–type and 67 ions are y-type fragments. The formation of only b and y-type ions is expected from cleavages of C-N bonds proceeding via vibrationally-excited ground state dissociation. H₂O and NH₃ losses from the b and
y ions are also noticed, with $\text{H}_2\text{O}$ losses being more widespread than $\text{NH}_3$ loss. The loss of water is energetically favorable from the protonated acidic group [40]. Ubiquitin has 7 threonine (T), 6 glutamic acid (E), 5 aspartic acid (D) and 3 serine (S) residues which may promote the widespread water loss. Low ($z = +1$) to high charge states ($z = +12$) of the b and y ions are observed, with the same fragment ion often being observed in many different charge states. For example, $b_{17}$ ion with +2, +3, and +4 charge states are detected at $m/z$ 952.5491, 635.3695, and 476.7778, respectively. The IRMPD sequence coverage of this charge state precursor ion is 44%.

The same precursor ion ($z = +13$) was then fragmented with UVPD in combination to IRMPD. In the consecutive scheme I, in which first IR then UV irradiation was performed, the total number of detected fragment ions is remarkably declined compared to UVPD (Figure 4a) alone. Despite this decrease, the number of b-type ions detected is significantly increased. The y-type ions remain same as UVPD alone. The a/x and c/z ions are also remarkably suppressed. Overall, the sequence coverage using this scheme is only 56% (Figure 3). In scheme I, IR laser pulses produce ubiquitin in its vibrationally hot electronic ground state (Figure 5a). Excitation promotes formation of hot ions and eventually ground state dissociation. And thus less parent ions are then available for UV fragmentation. UV excitation of hot ions is also possible.

In the consecutive scheme II, when irradiation with UV laser pulses is followed by IR irradiation, the overall number of detected fragment ions is considerably higher compared to scheme I (Figure 4a). The number of b and y-type ions is sharply increased as compared to both UVPD and scheme I. The relaxation following electronic excitation either by light emission, internal conversion through a conical intersection or via fragmentation is expected to be fast (typically ranging from fs to ns timescales). In scheme II, IR excitation is occurring after electronic excitation and relaxation has occurred. The UV laser promotes excited states dissociation whereas IR laser subsequently
leads to the ground state dissociation (Figure 5b). The combination of the two dissociation mechanisms explain the large amount of detected fragment ions in scheme II. In this case, the sequence coverage for this charge state precursor ion is 71% and is comparable to the one observed in UVPD.

The simultaneous introduction of UV and IR lasers (HiLoPD, high-low photodissociation, scheme III), on the +13 ion of ubiquitin produces a more diverse range of fragment ions than any of IRMPD, UVPD, Scheme I and Scheme II (Figure 4a). Exact masses and assignments of the ions detected in the combined UVPD and IRMPD of the +13 ion (m/z=659.8249) of ubiquitin are summarized in Table S4. Compare to UVPD, a substantial increase in b and y ions is observed in scheme III. The number of b-type ions increases from 5 to 48 while the number of y-type ions raises from 59 to 106 ions. The number of c-type ions is increased slightly from 10 to 18. The number of x and z-type of ions remained nearly same as UVPD, whereas the number of a-type ions is decreased noticeably from 68 to 24 ions with respect to UVPD. Secondary fragmentation which leads to the formation of d, v, and w ions is also significantly increased in scheme III compared to UVPD, scheme I and II (Figure S6). Due to the excess energy in scheme III, elimination of other groups such as R, CO and CONH are observed near the position of primary cleavage. High energy 157 and 193 nm UVPD has also reported the side-chain losses from the a+1/x+1 ions to form d, v and w ions [39]. Kjeldsen et al noticed the formation of d and w ions from the Leu and Ile comprising peptide in hot electron capture dissociation [41]. Zhang and Reilly also observed the formation of v, w_a, and w_b ions from x+1 ion of Leu and Ile containing peptides by UVPD at 157 nm [42]. It is interesting to note that ubiquitin has a total of 16 Leu and Ile residues, and thus formation of these secondary ions allows to distinguish isomeric residues. In addition, HiLoPD can be applied for de novo sequencing of peptides [43]. The sequence coverage of the +13 ion of
ubiquitin obtained at scheme III is 83%. The photophysical interpretation of this increase in fragmentation yield is that IR irradiation concomitant to UV irradiation can lead to vibrational excitation as well as excitation of higher electronic states and thus produce a rich fragmentation array (Figure 5c). Figure 6 shows the sequence maps obtained for the +13 charge state precursor ion in IRMPD, UVPD and HiLoPD (scheme III). The sequence coverage is improved in HiLoPD thanks to the combination of IR and UV irradiation. While IRMPD yields more fragment ions from the N-terminal, UVPD produces ions from the mid and C-terminal regions. Interestingly, HiLoPD able to produce fragments ions from all regions.

For a lower charge state (z = +8), the simultaneous irradiation of scheme III (HiLoPD) also showed a balanced fragmentation pattern. The total number of detected fragment ions of this charge state in scheme III is higher than both IRMPD and UVPD (Figure 4b) alone. A considerable number of b and y ions are observed in this lower charge state, and c-type ions are also detected. Only z-type ions remain essentially the same as in UVPD. The sequence coverage of the +8 ion of ubiquitin obtained with HiLoPD (scheme III) is 85%. Formation of d, v and w ions also is noticed for these charge states similar to +13 precursor ion.

Overall, IRMPD selectively produces b/y, and b-H2O/y-H2O ions whereas UVPD preferentially yields a+1/x+1, a/x, y-1, y-NH3, z, v and w ions (Figure S7a). The hybrid HiLoPD (scheme III) method generates b/y, b-H2O/y-H2O, x, x+1, y-1, y-2, y-NH3, z, v and w ions. Bond breaking and sequence coverage of high (z = +13) and low (z = +8) ions of ubiquitin obtained by IRMPD, UVPD and HiLoPD (scheme III) are shown in Figure S7b and S7c. HiLoPD allows to improve the efficiency of structural characterization of ubiquitin compared to IRMPD and UVPD. Moreover, sequence coverages obtained with HiLoPD are similar to those theoretically expected by combining UVPD and IRMPD (calculated IR+UV, see Figure S7c).
Conclusion

We have reported IRMPD, 213 nm UVPD, and HiLoPD patterns of ubiquitin in a hybrid quadrupole-Orbitrap mass spectrometer. Improved performance of IRMPD is observed when we use high laser powers coupled with a combination of very low pressure and longer irradiation time in the HCD cell. Significant numbers of b/y ions and neutral losses of NH₃ and H₂O are detected by IRMPD. Similar to excimer 193 nm UVPD, solid-state 213 nm UVPD can promote Cₓ–C cleavage generating abundant a/x, y, and z fragment ions for ubiquitin.

The Coupling of low-energy IRMPD and high-energy UVPD was implemented using three different irradiation schemes. In scheme I, where IR irradiation is followed by UV, the detected fragment ions are decreased as compared to UVPD only, which is mainly due to intense IR fragmentation prior to UV excitation. When UV irradiation was followed by IR (scheme II), the total number of detected fragment ion is slightly increased. In scheme III, while UV and IR lasers irradiation is simultaneous, the total number of detected fragment ions is increased. Excited and ground state dissociation channels promote widespread fragmentation in ubiquitin. Compared to UVPD, b/y-type ions are increased. We noticed that, while a/x fragment ions are decreasing, nearly equal number of d, v and w ions emerge, which can lead to identifying the isomeric residues in a protein.

Figure 1. Schematic representation of the execution of combined IRMPD and UVPD in the HCD cell of a hybrid quadrupole-Orbitrap mass spectrometer.
Figure 2. Impact of pressure on the fragmentation of the +12 charge state precursor ion (m/z=714.7279) of ubiquitin at 1 s irradiation time by IRMPD.
Figure 3. Combined IR and UV (schemes I, II, III), IRMPD and UVPD spectra of the +13 charge state precursor ion (m/z=659.8249) of ubiquitin. Isolation spectrum with no activation is also presented. Sequence coverages are indicated in brackets.
Figure 4. (a) Number of fragment ions detected by IRMPD, UVPD, and combined IR and UV (scheme I, II and III) of the +13 charge state precursor ion ($m/z=659.8249$) of ubiquitin. (b) Number of fragment ions detected by IRMPD, UVPD and HiLoPD (scheme III) of the +8 charge states precursor ion ($m/z=1071.5864$) of ubiquitin.
Figure 5. Ground and excited state dissociation channels in scheme I (a), scheme II (b) and scheme III (c)
Figure 6. Sequence coverage of the +13 charge state precursor ion ($m/z=659.8249$) of ubiquitin observed by IRMPD, UVPD and HiLoPD (scheme III).
Supporting Information

**Figure S1.** Consecutive and simultaneous irradiations of UV and IR laser in the combined high-low energy photon based method.
Figure S2. Effect of pressure on the collision frequency ($s^{-1}$) of the +12 ($m/z=714.7279$) ion of ubiquitin. Collision Cross-Section (CCS) value was taken from the ref. 34.
Figure S3. Effect of IRMPD irradiation time (s) on the +12 charge state precursor ion ($m/z=714.7279$) of ubiquitin at low pressure in the HCD cell ($9.3 \times 10^{-6}$ mbar).
Figure S4. Fragmentation yield based on the IRMPD irradiation time (s) for the +12 charge state precursor ion ($m/z$=714.7279) of ubiquitin at the lowest HCD pressure (~9.3 x10^{-6} mbar). Fragmentation yield = $\Sigma$(photofragments)/$\Sigma$(photofragments+precursor)
Figure S5. IRMPD sequence coverage (59%) of the +12 charge state precursor ion ($m/z=714.7279$) of ubiquitin.

Figure S6. Number of secondary fragment ions (d, v and w) detected by UVPD, and combined IR and UV (scheme I, II and III) of the +13 charge state precursor ion ($m/z=659.8249$) of ubiquitin.
Figure S7. (a) Comparative view of fragment ion types generated by IRMPD, UVPD and HiLoPD (scheme III) of the +13 charge state precursor ion ($m/z=659.8249$) of ubiquitin. (b) Number of bond breaks (c) Sequence coverage (%) obtained by IRMPD, UVPD, HiLoPD (scheme III), and theoretically combined IR and UV (Calculated (IR+UV)) of the +13 ($m/z=659.8249$) and +8 ($m/z=1071.5864$) charge state precursor ions of ubiquitin.
Table S1. Exact masses and assignments of ions detected by IRMPD of the +12 charge state precursor ion (m/z=714.7279) of ubiquitin.
