Abstract

The determinacy of lightface $\Delta^1_{2n+2}$ and boldface $\Pi^1_{2n+1}$ sets implies the existence of an $(\omega, \omega_1)$-iterable $M^\#_{2n+1}$.

1 Introduction

We prove the following theorem on the equivalence of determinacy principles and the existence of an iterable mouse with an odd number of Woodin cardinals:

Theorem 1.1. Suppose $n$ is a natural number. The following are equivalent:

1. $\Pi^1_{2n+1}$-determinacy + $\Delta^1_{2n+2}$-determinacy.

2. $\forall x \in \mathbb{R} (\text{there is an } (\omega_1, \omega_1) \text{-iterable } M^\#_{2n}(x)) \text{ and there is } N \in HC$ such that $L[N] \models \text{“there are } 2n+1 \text{ Woodin cardinals”}$.

3. There is an $(\omega, \omega_1)$-iterable $M^\#_{2n+1}$.
Theorem 1.1 solves the conjecture in [10, Section 4.2] for odd \( n \). The new ingredient in this paper is the direction \( 2 \Rightarrow 3 \) for \( n > 0 \). The proof of \( 3 \Rightarrow 1 \) appears in \([8, 9]\); \( 1 \Rightarrow 2 \) appears in \([10]\); \( 2 \Rightarrow 3 \) for \( n = 0 \) appears in \([12]\).

In the proof of \( 2 \Rightarrow 3 \) for \( n = 0 \) in \([12]\), the key idea of producing an iterable \( M_1^\# \) is the “bad sequence argument”: If \((T_i : i < \omega)\) is a stack of iteration trees on \( \mathcal{N} \) according to an iteration strategy, \( \mathcal{N}_i \) is the last model of \( T_i \) and \( \alpha \in \mathcal{N}_i \) for any \( i \), then for all but finitely \( i \), \( \pi^{T_i}(\alpha) = \alpha \). In practice, we take \( \alpha \) to be the Gödel code of \((u_1, \ldots, u_m)\) for any finite \( m \) in order to get proper class models whose iteration strategies respect \((u_1, \ldots, u_m)\), and finally by varying \( m \), the pseudo-comparison of these proper class models leads to an iterable mouse with a sharp on top of a Woodin cardinal.

This paper generalizes the “bad sequence argument” to the higher levels in the projective hierarchy. The main obstacle was the following: Say \( n = 1 \). The set of reals coding countable initial segments of \( L \) has complexity \( \Pi^1_1 \). However, the set of reals coding countable initial segments of \( M_2 \) is not \( \Pi^1_3 \). Due to this problem in complexity, the usual indiscernability arguments does not work any more with indiscernibles of \( M_2 \) above the Woodin cardinals of \( M_2 \). Here is the correct intuition: The correct higher level analog of \( L \) is not \( M_2 \), but rather \( L[T_3] \), where \( T_3 \) is the Moschovakis tree on \( \omega \times \delta^1_3 \) arising from the \( \Pi^1_3 \)-scale on the universal \( \Pi^1_3 \)-set. “countable initial segments of \( L \)” should correspond to \( \Pi^1_3 \)-iterable mice, as defined in \([11]\). \( \Pi^1_3 \)-iterable mice is precisely the collection of mice that are strictly smaller that \( M_2 |\delta^{M_2}_2 \) in the Dodd-Jensen prewellordering of mice, where \( \delta^{M_2} \) is the smallest Woodin of \( M_2 \). Instead of working with indiscernibles of \( M_2 \) above its Woodins, one needs to work with indiscernibles for \( L[T_3] \), or essentially, indiscernibles for iterates of \( M_2 \) below their Woodins. The indiscernibles for \( L[T_3] \) and its relationship with \( M_2^\# \) is worked out in \([16]\).

We briefly recall the background knowledge. Assume \( \Pi^1_3 \)-determinacy. Moschovakis \([7]\) shows that \( \Pi^1_3 \) has the scale property. \( T_3 \) is the tree of the \( \Pi^1_3 \)-scale on the universal \( \Pi^1_3 \) set. Steel \([11]\) defines the notion of \( \Pi^1_3 \)-iterable mouse. In this paper, \( \Pi^1_3 \)-iterable mice are by default countable and 2-small. For any real \( x \), the set of reals coding \( \Pi^1_3 \)-iterable \( x \)-mice is \( \Pi^1_3(x) \), uniformly in \( x \). \( \Pi^1_3 \)-iterable \( x \)-mice are genuinely \((\omega_1, \omega_1)\)-iterable. If \( \mathcal{M} \) and \( \mathcal{N} \) are both \( \Pi^1_3 \)-iterable \( x \)-mouse, \( \mathcal{M} \leq DJ(x) \mathcal{N} \) means that in the comparison between \( \mathcal{M} \) and \( \mathcal{N} \), the main branch on the \( \mathcal{M} \)-side does not drop. \( \leq DJ(x) \) is a prewellordering on the set of \( \Pi^1_3 \)-iterable \( x \)-mouse. We denote by

\[ \|\mathcal{M}\|_{DJ(x)} \]

the \( \leq DJ(x) \)-rank of \( \mathcal{M} \). The length of \( \leq DJ(x) \) is at most \( \delta^1_3 \). If \( \mathcal{M} \) is a \( \Pi^1_3 \)-
iterable $x$-mouse, the following sets are $\Delta^1_1(x)$, uniformly in $x$:

$$\{ z : z \text{ codes a } \Pi^1_3 \text{-iterable } x \text{-mouse } N_z \land \| N_z \|_{DJ(x)} < \| M \|_{DJ(x)} \},$$

$$\{ z : z \text{ codes a } \Pi^1_3 \text{-iterable } x \text{-mouse } N_z \land \| N_z \|_{DJ(x)} = \| M \|_{DJ(x)} \}.$$ 

If $M$ is a $\Pi^1_3$-iterable $x$-mouse,

$$\mathcal{M}^x_\infty$$

denotes the direct limit of all countable non-dropping iterates of $\mathcal{M}$ and

$$\pi^{x}_{\mathcal{M},\infty} : \mathcal{M} \to \mathcal{M}^x_\infty$$

denotes the direct limit map. $\mathcal{M}^x_\infty$ depends only on $x$ and $\| M \|_{DJ(x)}$, so for $\alpha = \| M \|_{DJ(x)}$, we denote

$$N^{x}_{\alpha,\infty} = \mathcal{M}^x_\infty.$$ 

If $A$ is a countable self-wellordered set, we can make sense of $\Pi^1_3$-iterable $A$-mice and $\leq_{DJ(A)} \| \cdot \|_{DJ(A)}$, $\mathcal{M}^A_\infty$, $\pi^A_{\mathcal{M},\infty}$, $N^A_{\alpha,\infty}$. As a consequence of Silver’s dichotomy on $\Delta^1_3$-equivalence relations (cf. [3], [16, Corollary 2.14]) and $Q$-theory (cf. [5], [1]), we are able to compare the Dodd-Jensen rank of $\Pi^1_3$-mice over different reals in a $\Sigma^1_4$ way that is absolute between transitive models closed under the $M^#_1$-operator:

**Theorem 1.2** ([16 Corollary 2.15]). Assume $\Delta^1_2$-determinacy. Then the relations

$$z \text{ codes a } \Pi^1_3 \text{-iterable } x \text{-mouse } P_z \land z' \text{ codes a } \Pi^1_3 \text{-iterable } x' \text{-mouse } P_{z'}$$

$$\land \| P_z \|_{DJ(x)} = \| P_{z'} \|_{DJ(x')}$$

and

$$z \text{ codes a } \Pi^1_3 \text{-iterable } x \text{-mouse } P_z \land z' \text{ codes a } \Pi^1_3 \text{-iterable } x' \text{-mouse } P_{z'}$$

$$\land \| P_z \|_{DJ(x)} = \| P_{z'} \|_{DJ(x')} \land$$

$$m \in \omega \text{ codes } \alpha \in P_z \text{ relative to } z \land m' \in \omega \text{ codes } \alpha' \in P_{z'} \text{ relative to } z'$$

$$\land \pi^{x}_{P_z,\infty}(\alpha) = \pi^{x'}_{P_{z'},\infty}(\alpha')$$

are both $\Sigma^1_4$ and absolute between transitive models which contain $\{ z, x, z', x' \}$ and are closed under the $M^#_1$-operator.

Assume $\forall x \in \mathbb{R}$ (there is an $(\omega_1, \omega_1)$-iterable $M^#_2$). Steel [13] shows that:

1. For any real $x$, $\leq_{DJ(x)}$ has length $\delta^1_3$.
2. Let $M_{2,\infty}^\#(x)$ be the direct limit of all countable non-dropping iterates of $M_2^\#(x)$. Then $\delta_3$ is the least strong up to the least Woodin in $M_{2,\infty}^\#(x)$ and $M_{2,\infty}^\#(x) = L_{\delta_3}[T_3, x]$.

We say that a $\Pi_3^1$-iterable $x$-mouse $P$ is full iff for any $\Pi_3^1$-iterable $P$-mouse $R$, $R$ can be regarded as an $x$-mouse, i.e., for any $\rho < o(P)$, for any $A \subseteq \rho$, $A \in P$ iff $A \in R$. Equivalently, $P$ is full iff $M_2(P)$ does not contain bounded subsets of $o(P)$ that are not in $P$. If $P$ is full, then $P^\infty = M_{2,\infty}^\#(x)|\gamma$ where $\gamma = o(P^\infty)$ is a cardinal and cutpoint in $M_{2,\infty}^\#(x)$.

Put $L[T_3] = \bigcup_{x \in \mathbb{R}} L[T_3]$. The following theorem shows the equivalence of $L[T_3,x]$-indiscernibles and $M_{2,\infty}^\#(x)$:

**Theorem 1.3** (Zhu [16]). There are countably complete $L[T_3]$-measures $(\mu_n : n < \omega)$ on $(\delta_3)^2$ such that for any $x \in \mathbb{R}$,

1. for $\mu_n$-a.e. $(\alpha, \beta)$, if $\|R\|_{DJ(x)} = \beta$, then $R$ is full and $R^\infty = N_{\beta,\infty}^x = M_{2,\infty}^\#(x)|\beta$;

2. letting

\[
(x^3)^n = \{\varphi^1 : \text{for } \mu_n\text{-a.e. } (\alpha, \beta), N_{\beta,\infty}^x \models \varphi(\alpha)\}
\]

and

\[
x^{3^\#} = \oplus_{n<\omega}(x^{3^\#})^n,
\]

then

\[
x^{3^\#} \equiv_m M_{2}^\#(x),
\]

uniformly in $x$.

Fixing $n$, $\mu_n$ is the higher level analog of the $L = \text{DEF} \bigcup_{x \in \mathbb{R}} L[x]$-measure $\nu_n$ on $(\omega_1)^{n}$, where $A \in \nu_n$ iff for some $x \in \mathbb{R}$, $A$ contains all the increasing $n$-tuples of countable $x$-indiscernibles. For the reader familiar with [16], $\mu_n$ can be taken as the $L[T_3]$-measure arising from the level-3 tree $Y_n$ so that $[\emptyset]_{Y_n} = u_n + \omega$.

2 The bad sequence argument

We prove $2 \Rightarrow 3$ in Theorem [13] for $n = 1$. The general case makes no essential difference based on [16].

**Definition 2.1.** A premouse $P$ is suitable iff there is $\delta \in P$ such that

1. $P = M_{2}^\#(P|\delta)|((\delta^+)^{M_{2}^\#(P|\delta)})$. 

4
2. \( \mathcal{P} \) satisfies the following.

(a) \( \delta \) is Woodin.

(b) \( \forall \eta < \delta \forall a \in \mathcal{P}|\eta \) (the \( L[\vec{E}] \)-construction above \( a \) with critical points above \( \eta \) reaches \( M^2_2(a) \)). If \( \mathcal{N} \) is a \( \text{card}(\mathcal{N})+1 \)-iterable mouse (over \( \emptyset \)), then let

\[
M^2_2(\mathcal{N}) = M^2_2(\mathcal{N})|\alpha
\]

regarded as a \( \emptyset \)-mouse, where \( \alpha \) is the least such that \( \exists \rho < o(\mathcal{N}) \exists A \subseteq \rho(A \in \text{rud}(M^2_2(\mathcal{N})|\alpha) \setminus \mathcal{N}) \). The partial iteration strategy guided by 2-small mice is the partial strategy \( \Sigma \) so that

\[
\Sigma(\mathcal{T}) = b \iff Q(b, \mathcal{T}) = M^2_2(\mathcal{M}(\mathcal{T})) \neq M^2_2(\mathcal{M}(\mathcal{T})).
\]

(c) \( \forall \eta < \delta \mathcal{P}|\delta \) is \( (\eta, \eta) \)-iterable according to the partial iteration strategy guided by 2-small mice.

(d) \( \forall \eta < \delta \mathcal{M}_2^\#(\mathcal{P}|\eta) = \eta \) is not Woodin.

If \( \mathcal{P} \) is suitable, \( \delta^\mathcal{P} \) denotes its Woodin, and \( \mathcal{P}^- = \mathcal{P}|\delta^\mathcal{P} \). If \( \mathcal{P} \) is also countable, \( \mathcal{P} \) itself can be regarded as a full \( \Pi^1_3 \)-iterable \( \mathcal{P}^- \)-mouse. In fact, a countable premouse \( \mathcal{P} \) is suitable iff \( \mathcal{P} \) satisfies the first order property in Clause 2 in Definition 2.1 and \( \mathcal{P} \) is full. If \( \widehat{\mathcal{P}} \) is another \( \Pi^1_3 \)-iterable \( \mathcal{P}^- \)-mouse, \( \widehat{\mathcal{P}} \) can also be regarded as a \( \emptyset \)-premouse, and we have \( \mathcal{P} \preceq \widehat{\mathcal{P}} \) iff \( \widehat{\mathcal{P}} \) is full.

**Theorem 2.2** (Mitchell-Steel [6]). If \( \forall x \in \mathbb{R} (\text{there is an} (\omega_1, \omega_1) \text{-iterable} M^\#_2(x)) \) and \( \exists \mathcal{N} \in HC \ L[\mathcal{N}] \models \text{“there are three Woodin cardinals”} \), then there is a countable suitable premouse.

The following condensation principle is an easy generalization of [12, Lemma 3.3]. Its proof can be found in e.g. [10, Lemma 3.3].

**Lemma 2.3.** If \( \mathcal{P} \) is countable and suitable, \( \widehat{\mathcal{P}} \) is a \( \Pi^1_3 \)-iterable \( \mathcal{P}^- \)-mouse, \( \mathcal{H} \) is the transitive collapse of \( \text{Hull}^{\widehat{\mathcal{P}}}_\omega \), the \( \widehat{\mathcal{P}} \)-definable points where \( \widehat{\mathcal{P}} \) is regarded as a \( \emptyset \)-premouse, then \( \mathcal{H} \) (regarded as a \( \emptyset \)-premouse) is an initial segment of \( \mathcal{P}|\omega^\mathcal{P}_1 \).

**Definition 2.4.** Let \( \mathcal{T} \) be a normal iteration tree on a suitable \( \mathcal{P} \). \( \mathcal{T} \) is short iff \( \forall \alpha \leq \text{lh}(\mathcal{T}) \) limit, \( M_2(\mathcal{M}(\mathcal{T} \upharpoonright \alpha)) \models \text{“} \delta(\mathcal{T} \upharpoonright \alpha) \text{ is not Woodin”} \). \( \mathcal{T} \) is maximal iff \( \mathcal{T} \) is not short.

**Definition 2.5.** Suppose \( \mathcal{P} \) is suitable. \( \mathcal{P} \) is short-tree-iterable iff for any putative short tree \( \mathcal{T} \) on \( \mathcal{P} \), for any \( \Pi^1_3 \)-iterable \( \mathcal{P}^- \)-mouse \( \widehat{\mathcal{P}} \), letting \( \widehat{\mathcal{T}} \) be \( \mathcal{T} \) construed as a putative tree on \( \widehat{\mathcal{P}} \),
1. if \( \hat{T} \) has a last model \( \mathcal{M}_{\alpha}^{\hat{T}} \), then either
   
   (a) \([0, \alpha]_T \) drops, \( \mathcal{M}_{\alpha}^{T} \) is \( \Pi^1_3 \)-iterable, or
   
   (b) \([0, \alpha]_T \) does not drop, \( \mathcal{M}_{\alpha}^{\hat{T}} \) is a \( \Pi^1_3 \)-iterable \( \pi^{T}_{0,\alpha}(\mathcal{P}^-) \)-mouse.

2. If \( \text{lh}(\mathcal{T}) \) is limit, \( \mathcal{T} \) is short, then \( \mathcal{T} \) has a cofinal branch \( b \) such that
   
   \[
   Q(b, \mathcal{T}) = M_2^{\mathcal{T}}(\mathcal{M}(\mathcal{T})),
   \]
   
   where \( M_2^{\mathcal{T}}(\mathcal{M}(\mathcal{T})) = M_2^{\hat{T}}(\mathcal{M}(\mathcal{T}))^{\alpha} \) regarded as a \( \theta \)-mouse, \( \alpha \) is the least such that \( \exists \rho < \delta(\mathcal{T}) \exists A \subseteq \rho \ (A \in M_2^{\#}(\mathcal{M}(\mathcal{T}))^{\alpha + 1 \setminus \mathcal{M}(\mathcal{T}))} \).

**Lemma 2.6.** If \( \mathcal{P} \) is suitable, then \( \mathcal{P} \) is short-tree-iterable.

**Proof.** Suppose not. There is then a putative short tree \( \mathcal{T} \) on \( \mathcal{P} \) and a \( \Pi^1_3 \)-iterable \( \mathcal{P}^- \)-mouse \( \hat{\mathcal{P}} \) such that either

1. \( \text{lh}(\mathcal{T}) = \alpha + 1 \) is a successor, \([0, \alpha]_T \) drops, \( \mathcal{M}_{\alpha}^{T} \) is not \( \Pi^1_3 \)-iterable, or

2. \( \text{lh}(\mathcal{T}) = \alpha + 1 \) is a successor, \([0, \alpha]_T \) does not drop, letting \( \hat{T} \) be \( \mathcal{T} \) con-

3. \( \text{lh}(\mathcal{T}) = \lambda \) is a limit, there is a \( \delta(\mathcal{T}) \)-sound, \( \Pi^1_3 \)-iterable \( M(\mathcal{T}) \)-mouse \( \mathcal{R} \)
   that can be regarded as an \( \theta \)-premouse with \( \rho_{\mathcal{R}}(\mathcal{R}) < \delta(\mathcal{T}) \), but there

The existence of a \( \mathcal{P} \)-bad pair \((\mathcal{T}, \hat{\mathcal{P}})\) is \( \Sigma^1_1 \) in the code of \( \mathcal{P} \). By Steel [111],

\[
M_2(z) \prec_{\Sigma^1_1} V \quad \text{for any real} \ z.
\]

Hence, a bad pair can be found in \( M_2(\mathcal{P})^{\text{Coll}(\omega, \mathcal{P})} \).

Working in \( M_2(\mathcal{P}) \), take a countable elementary substructure \( \mathcal{N} \prec M_2(\mathcal{P})^{\eta} \),

where \( \eta \) is the successor of \( \text{o}(\mathcal{P}) \) in \( M_2(\mathcal{P}) \). \( \mathcal{H} \) is the transitive collapse of \( \mathcal{N} \),

which is by Lemma 2.3 an initial segment of \( \mathcal{P} \). Let \( \mathcal{Q} \) be the image of \( \mathcal{P} \)

under the transitive collapsing map. Take \( g \in \mathcal{P} \) which is generic over \( \mathcal{H} \) for

\( \text{Coll}(\omega, \mathcal{Q}) \). So \( \mathcal{H}[g] \models \text{“there is a} \ \mathcal{Q} \text{-bad pair} \ (\mathcal{U}, \hat{\mathcal{Q}}) \text{”} \).

Note that \( \mathcal{H}[g] \models \text{“I am closed under the} \ M^\#_T \text{-operator”} \), therefore as \( \mathcal{H} \subseteq \mathcal{P} \), the \( M^\#_T \)-operators are computed correctly in \( \mathcal{H}[g] \), which implies that \( \mathcal{H}[g] \prec_{\Sigma^1_3} \mathcal{P} \) by genericity

iterations (cf. [111] Section 7.2]). So \((\mathcal{U}, \hat{\mathcal{Q}})\), being a \( \mathcal{Q} \)-bad pair from the point

of view of \( \mathcal{H}[g] \), is also seen as a \( \mathcal{Q} \)-bad pair in \( \mathcal{P} \). However, \( \mathcal{Q} \prec \mathcal{P} \) and \( \mathcal{Q} \)

is \((\omega_1, \omega_1)\)-iterable in \( \mathcal{P} \) by suitably. Contradiction!

If \( \mathcal{P} \) is suitable and \( \mathcal{T} \) is a short tree on \( \mathcal{P} \) such that \( \pi^T \) exists, we can
define an order preserving function

\[
g^T : \delta^1_3 \to \delta^1_3
\]

6
as follows: If $\mathcal{P}'$ is a $\Pi^1_3$-iterable $\mathcal{P}^-$-mouse, let $f_T(\mathcal{P}')$ be the last model of $\mathcal{T}$ construed as a tree on $\mathcal{P}'$, and define

$$g^T(||\mathcal{P}'||_{\mathcal{P}^-}) = ||f_T(\mathcal{P}')||_{\pi_T(\mathcal{P}^-)}.$$ 

$g^T$ is well-defined: Suppose $||\mathcal{P}'||_{\mathcal{P}^-} = ||\mathcal{P}''||_{\mathcal{P}^-}$ and suppose without loss of generality that $\mathcal{P}''$ is a non-dropping iterate of $\mathcal{P}'$ via $\mathcal{U}$ above $\mathcal{T}$. We would like to show that $||f_T(\mathcal{P}')||_{\pi_T(\mathcal{P}^-)} = ||f_T(\mathcal{P}'')||_{\pi_T(\mathcal{P}^-)}$. On the one hand, the tree $\mathcal{P}'$-to-$f(\mathcal{P}')$ is copied to the tree $\mathcal{P}''$-to-$f(\mathcal{P}'')$ according to $\pi^T$ (both trees are just $\mathcal{T}$ construed on different models), so $\pi^T$ induces a copying map from $f^T(\mathcal{P}')$ to $f^T(\mathcal{P}'')$, giving that $||f_T(\mathcal{P}')||_{\pi_T(\mathcal{P}^-)} \leq ||f_T(\mathcal{P}'')||_{\pi_T(\mathcal{P}^-)}$. On the other hand, we can copy $\mathcal{U}$ to a tree on $f(\mathcal{P}')$ according to the iteration map from $\mathcal{P}'$ to $f(\mathcal{P}')$, leading to an iteration tree $\mathcal{V}$ on $f(\mathcal{P}')$ with last model $\mathcal{Q}$ so that $\pi^V$ exists. Note that $\mathcal{U}$ is above $\mathcal{P}^-$ while $\mathcal{T}$ is based on $\mathcal{P}^-$. The technique in [13, Lemma 3.2] enables us to define a map from $f(\mathcal{P}'')$ to $\mathcal{Q}$, giving that $||f_T(\mathcal{P}'')||_{\pi_T(\mathcal{P}^-)} \leq ||f_T(\mathcal{P}')||_{\pi_T(\mathcal{P}^-)}$. A similar argument shows that $g^T$ is order preserving.

**Corollary 2.7.** Suppose $\mathcal{P}$ is suitable and $\mathcal{T}$ is a short tree on $\mathcal{P}$ with last model $\mathcal{Q}$ such that $\pi^T$ exists. Then $\mathcal{Q}$ is suitable.

**Proof.** All the first-order-in-$\mathcal{P}$ properties in Definition 2.1 are preserved by elementarity. We need to show fullness. For any $\mathcal{P}'$, a full $\Pi^1_3$-iterable $\mathcal{P}^-$-mouse, $\mathcal{P}' \models o(\mathcal{P}) = (\delta^\mathcal{P})^+$, and hence by elementarity, $f_T(\mathcal{P}') \models o(\mathcal{Q}) = (\pi^T(\delta^\mathcal{P}))^+$. If $\mathcal{Q}'$ is any full $\Pi^1_3$-iterable $\mathcal{Q}[\pi^T(\delta^\mathcal{P})]$-mouse, we may pick such $\mathcal{P}'$ with $g^T(||\mathcal{P}'||_{\mathcal{P}^-}) > ||\mathcal{Q}'||_{\pi_T(\mathcal{P}^-)}$, implying that $\mathcal{Q}' \models o(\mathcal{Q}) = (\pi^T(\delta^\mathcal{P}))^+$. Hence $\mathcal{Q}$ is suitable and $\delta^\mathcal{Q} = \pi^T(\delta^\mathcal{P})$.

**Definition 2.8.** Let $\mathcal{P}$ be suitable. $\mathcal{Q}$ is called a pseudo-normal-iterate of $\mathcal{P}$ iff $\mathcal{Q}$ is suitable and there is a normal tree $\mathcal{T}$ on $\mathcal{P}$ such that either $\mathcal{Q}$ is the last model of $\mathcal{T}$, $\pi^T$ exists, or $\mathcal{Q} = M_2(\mathcal{M}(\mathcal{T}))((\delta(\mathcal{T}))^+)M_2(\mathcal{M}(\mathcal{T}))$.

**Definition 2.9.** Let $\mathcal{P}$ be suitable. $((\mathcal{T}_i : i < k), (\mathcal{P}_i : i \leq k))$ is called a finite full stack on $\mathcal{P}$ iff $\mathcal{P}_0 = \mathcal{P}$ and for each $i$, $\mathcal{P}_{i+1}$ is a pseudo-normal-iterate of $\mathcal{P}_i$ witnessed by $\mathcal{T}_i$.

**Definition 2.10.** Suppose $\mathcal{P}$ is countable and suitable, $\alpha < \beta < \delta^1_3$, and $\alpha < \mathcal{N}^{\mathcal{P}}_{\beta,\infty}$. Then

1. $Th^{\mathcal{P}}_{(\alpha,\beta)} = \{ (\varphi, \xi) : \xi < \delta^\mathcal{P}, \mathcal{N}^{\mathcal{P}}_{\beta,\infty} \models \varphi(\xi, \alpha) \}$.
2. $\gamma^{\mathcal{P}}_{(\alpha,\beta)} = \sup(\text{Hull}^{\mathcal{N}^{\mathcal{P}}_{\beta,\infty}}(\{\alpha\}) \cap \delta^\mathcal{P})$.
3. $H^{\mathcal{P}}_{(\alpha,\beta)} = \text{Hull}^{\mathcal{N}^{\mathcal{P}}_{\beta,\infty}}(\gamma^{\mathcal{P}}_{(\alpha,\beta)} \cup \{\alpha\})$. 

7
4. By Theorem 1.3, define \((\mathcal{P}^{-})^{3\#}_{n} = Th^{P}_{(\alpha,\beta)}\) for \(\mu_{n}\)-a.e. \((\alpha, \beta)\) and \((\mathcal{P}^{-})^{3\#} = \oplus_{n<\omega} (\mathcal{P}^{-})^{3\#}_{n}\).

5. \(\gamma_{3\#}^{\mathcal{P}} = \gamma^{\mathcal{P}}_{(\alpha,\beta)}\) for \(\mu_{n}\)-a.e. \((\alpha, \beta)\).

6. \(H^{\mathcal{P}}_{3\#} = H^{\mathcal{P}}_{(\alpha,\beta)}\) for \(\mu_{n}\)-a.e. \((\alpha, \beta)\).

Suppose \(\mathcal{T}\) is a normal iteration tree on \(\mathcal{P}\) and \(b\) is a cofinal branch of \(\mathcal{T}\). \(b\) is said to respect \((\alpha, \beta)\) iff \(Q = \mathcal{M}^{\mathcal{T}}_{b}\) is suitable and

\[ \pi_{b}^{T}(Th^{P}_{(\alpha,\beta)}) = Th^{Q}_{(\alpha,\beta)}. \]

\(b\) is said to respect \((\cdot)^{3\#}\) iff \(Q = \mathcal{M}^{T}_{b}\) is suitable and

\[ \pi_{b}^{T} ((\mathcal{P}^{-})^{3\#}_{n}) = (Q^{-})^{3\#}_{n}. \]

\(\mathcal{P}\) is \(n\)-iterable iff for any full finite stack ((\(\mathcal{T}_{i} : i < k\)), (\(\mathcal{P}_{i} : i \leq k\))) on \(\mathcal{P}\), there is \((b_{i} : i < k)\) such that each \(b_{i}\) respects \((\cdot)^{3\#}_{n}\).

By Theorem 1.3 for any countable suitable \(\mathcal{P}\), we must have

\[ \sup_{n<\omega} \gamma_{3\#}^{\mathcal{P}} = \delta^{\mathcal{P}}. \]

**Lemma 2.11.** Let \(n < \omega\). Then there is a countable, \(n\)-iterable suitable mouse.

**Proof.** Otherwise, there is ((\(\mathcal{T}_{i} : i < \omega\)), (\(\mathcal{P}_{i} : i < \omega\))) such that \(\mathcal{P}_{0} = \mathcal{P}\) is suitable, \(\mathcal{T}_{i}\) is a normal tree on \(\mathcal{P}_{i}\), but for infinitely many \(i\), there is no cofinal branch \(b_{i}\) through \(\mathcal{T}_{i}\) that respects \((\cdot)^{3\#}\).

Fix \(z \in \mathbb{R}\) coding \((\vec{T}, \bar{\mathcal{P}})\). Fix \(\alpha < \beta < \delta^{1}_{3}\) such that for any \(i\), \((\mathcal{P}_{i})^{\beta}_{3\#} = Th^{P}_{(\alpha,\beta)}\) and if \(\|\mathcal{R}\|_{D.J(\mathcal{P}^{-})} = \beta\), then \(\mathcal{R}\) is full and \(\mathcal{R}_{\infty} = \mathcal{N}_{\beta,\infty}^{\mathcal{P}_{i}^{-}} = M_{2,\infty}(\mathcal{P}_{i}^{-})\|\beta.\)

Thus, for infinitely many \(i\), there is no cofinal branch \(b_{i}\) through \(\mathcal{T}_{i}\) that respects \((\alpha, \beta)\). We call \((\vec{T}, \bar{\mathcal{P}})\) an \((\alpha, \beta)\)-bad sequence based on \(\mathcal{P}\).

Let \(\hat{\mathcal{P}}\) be a \(\Pi^{1}_{3}\)-iterable \(\mathcal{P}^{-}\)-mouse and \(\eta \in \hat{\mathcal{P}}\) so that \(\|\hat{\mathcal{P}}\|_{\mathcal{P}^{-}} = \beta\) and \(\pi_{\hat{\mathcal{P}},\infty}^{\mathcal{P}^{-}}(\eta) = \alpha\). By Theorem 1.2 the statement

"There is an \((\pi_{\hat{\mathcal{P}},\infty}^{\mathcal{P}^{-}}(\eta), \|\hat{\mathcal{P}}\|_{\mathcal{P}^{-}})\)-bad sequence \((\vec{T}, \bar{\mathcal{P}})\) based on \(\mathcal{P}\)"

is \(\Sigma^{1}_{4}\) in the code of \(\hat{\mathcal{P}}\) and absolute between transitive models closed under the \(M^{\#}_{\mathcal{P}}\)-operator. It is a true statement in \(V\), so by absoluteness, true \(M_{2}(\hat{\mathcal{P}})^{Col(\omega, \bar{\mathcal{P}})}\) as well. By our choice of \(\beta\), \(\hat{\mathcal{P}}\) is full, so \(M_{2}(\hat{\mathcal{P}})\) can be regarded as an \(\Phi\)-premouse and \(o(\hat{\mathcal{P}})\) is a cardinal and cutpoint in \(M_{2}(\hat{\mathcal{P}})\). As in the proof of Lemma 2.6 we get \(\mathcal{H} \triangleleft \mathcal{P}\) and \(g \in \mathcal{P}\) generic over \(\mathcal{H}\), \(\{Q, \bar{Q}, \bar{U}, \xi\} \in \mathcal{H}[g]\) so that
$\mathcal{H}[g] \models (\bar{U}, \bar{Q})$ is an $(\pi_{\bar{Q},\infty}^\sim(\eta), \|\hat{Q}\|_{DJ(\bar{Q}^-)})$-bad sequence based on $\bar{Q}$.

As $\mathcal{H}[g] \prec_{\Sigma^1_3} \mathcal{P}$, we have $(\bar{\alpha}, \bar{\beta}) \in \mathcal{P}$ so that

$\mathcal{P} \models (\bar{U}, \bar{Q})$ is an $(\bar{\alpha}, \bar{\beta})$-bad sequence and $\|\hat{Q}\|_{DJ(\bar{Q}^-)} = \bar{\beta}, \pi_{\bar{Q},\infty}^\sim(\eta) = \bar{\alpha}$.

For the rest of this proof, we work in $\mathcal{P}$. Pick $\hat{Q}_i$ and $\xi_i \in \hat{Q}_i$ so that

$\mathcal{P} \models \|\hat{Q}_i\|_{\bar{Q}^-} = \bar{\beta} \land \pi_{\bar{Q},\infty}^\sim(\xi_i) = \bar{\alpha}$.

We define $(R_i, S_i, b_i, \hat{U}_i : i < \omega)$ and $(V_i, W_i : 1 \leq i < \omega)$ inductively such that:

1. $R_i \triangleright Q_i$, $R_i$ is $\Pi^1_3$-iterable above $Q_i^-$, $R_0 = \hat{Q}_0$;
2. $\hat{U}_i$ is $U_i$ construed as an iteration tree on $R_i$;
3. $b_i$ is the cofinal branch of $\hat{U}_i$ chosen by the internal strategy of $\mathcal{P}$;
4. $S_{i+1}$ is the last model of $\hat{U}_i \triangleright b_i$;
5. $(V_i, W_i)$ is the comparison of $(S_i, \hat{Q}_i)$ and $R_i$ is the last model of $W_i$.

By monotonicity of the function $g^{\hat{U} \triangleright b_i} : \delta^1_3 \rightarrow \delta^1_3$, we can inductively see that for each $i$, $\|S_i\|_{DJ(\hat{Q}_i^-)} \geq \bar{\beta}$, the main branch of $W_i$ does not drop, and $\|R_i\|_{DJ(\hat{Q}_i^-)} \geq \bar{\beta}$. The stack

$\hat{U}_0 \triangleright b_0 \triangleright V_1 \triangleright \hat{U}_1 \triangleright b_1 \triangleright V_2 \triangleright \ldots$

9
is according to the internal strategy of $\mathcal{P}$. So for some $m < \omega$, we have for any $i > m$, $\pi_{bi}^{\mathcal{M}_i}$ exists and $\pi_{vi}^{\mathcal{N}_i}$ exists. The map $\pi_{\mathcal{M}_i}^{\mathcal{N}_i} - b_i - v_{i+1}$ induces a map $\tau_i : (\mathcal{R}_i)_{\infty}^{-} \to (\mathcal{R}_i)_{\infty}^{Q_i}$ so that $\tau_i \circ \pi_{\mathcal{R}_i,\infty}^{\mathcal{N}_i} = \pi_{\mathcal{R}_i,\infty}^{Q_i} \circ \pi_{\mathcal{M}_i}^{\mathcal{N}_i} - b_i - v_{i+1}$. Clearly $\tau_i(\bar{\beta}) \geq \beta$. So $\pi_{\mathcal{M}_i}^{\mathcal{N}_i} - b_i - v_{i+1} \circ \pi_{\mathcal{N}_i}^{\mathcal{M}_i}(\xi_i) \geq \pi_{\mathcal{N}_i}^{\mathcal{M}_i}(\xi_{i+1})$. So we must have some $m < n < \omega$ so that for any $i > m$, $\pi_{\mathcal{M}_i}^{\mathcal{N}_i} - b_i - v_{i+1} \circ \pi_{\mathcal{N}_i}^{\mathcal{M}_i}(\xi_i) = \pi_{\mathcal{N}_i}^{\mathcal{M}_i}(\xi_{i+1})$. In other words, for any $i > m'$, $b_i$ respects $(\bar{\alpha}, \bar{\beta})$, contradicting to the assumption that $(\mathcal{U}, \mathcal{Q})$ is an $(\bar{\alpha}, \bar{\beta})$-bad sequence. 

By Lemma 2.11, we can find $(\mathcal{P}_n : n < \omega)$ where $\mathcal{P}_n$ is a countable, $n$-iterable suitable premouse. The pseudo-comparison leads to countable iteration trees $(\mathcal{T}_n : n < \omega)$ and a suitable $\mathcal{Q}$ so that $\mathcal{T}_n$ is an iteration tree on $\mathcal{P}_n$ with last model $\mathcal{Q}$. $\mathcal{Q}$ is then $n$-iterable for any $n < \omega$. The usual limit branching argument (cf. [12, Lemma 4.12]) gives an $(\omega, \omega)$-iteration strategy for $\mathcal{Q}$: For instance, suppose $\mathcal{T}$ is a normal tree on $\mathcal{Q}$ with pseudo-normal-iterate $\mathcal{R}$. Let

$$b_i = \cap \{ b : b \text{ is a branch through } \mathcal{T} \land b \text{ respects } (\cdot)^3\# \}.$$ 

Then $b_i \subseteq b_{i+1}, \gamma_{3\#}^{\mathcal{M}_i}_{\max,b_i} = \gamma_{3\#}^{\mathcal{R},i}$ and we have an isomorphism $\sigma_i : H_{3\#}^{\mathcal{M}_i}_{\max,b_i} \cong H_{3\#}^{\mathcal{R},i}$. Let $b = \cup_{i<\omega} b_i$. Then $\delta^{\mathcal{M}_i} \sup_{b} \geq \sup_{n<\omega} \gamma_{3\#}^{\mathcal{R},n} = \delta^{\mathcal{R}}$. So $b$ must be a cofinal branch. There is a canonical map

$$\tau : \mathcal{R} \to \mathcal{M}_b^{\mathcal{T}}$$

defined by $\tau(a) = \pi_{a,b} \circ \sigma_i^{-1}(a)$ for $\alpha < \max(b_i)$ and $a \in H_{3\#}^{\mathcal{R},i}$. $\tau$ is onto $\mathcal{M}_b^{\mathcal{T}}$ because $\mathcal{M}_b^{\mathcal{T}_{\max,b_i}} = \cup_{n<\omega} H_{3\#}^{\mathcal{M}_i}_{\max,b_i}$. Therefore, $\tau$ is the identity, $\mathcal{M}_b^{\mathcal{T}} = \mathcal{R}$ and $b$ respects $(\cdot)^3\#$.

In other words, by Theorem 1.3, $\mathcal{M}_2^\#(\mathcal{Q})$, regarded as a $\emptyset$-mouse, has a partial $(\omega, \omega_1)$-iteration strategy $\Gamma$ with respect to stacks of normal trees based on $\mathcal{Q}$ but that moves the top $\mathcal{M}_2^\#$-component correctly, i.e., whenever $\mathcal{U}$ is according to $\Gamma$ based on $\mathcal{Q}$ and the main branch of $\mathcal{U}$ does not drop, the last model of $\mathcal{U}$ must be $\mathcal{M}_2^\#(\pi^{\mathcal{U}}(\mathcal{Q}))$. Also by definition of suitability, whenever $\mathcal{U}$ is according to $\Gamma$ based on $\mathcal{Q}$ but the main branch of $\mathcal{U}$ drops, the last model of $\mathcal{U}$ is $\Pi_2^1$-iterable. By the technique in [12], $\mathcal{M}_2^\#(\mathcal{Q})$ is $(\omega, \omega_1)$-iterable. $\mathcal{M}_3^\#(\mathcal{Q})$ has a sharp above three Woodins, so by taking its $\Sigma_1$-Skolem hull, we get an $(\omega, \omega_1)$-iterable $\mathcal{M}_3^\#$. This finishes the proof of Theorem 1.3 for $n = 1$.
