ARTHRITIS AS A MANIFESTATION OF INFECTIVE ENDOCARDITIS

Uvarova K. H.

Introduction. Diagnosis of infective endocarditis is a challenging task for clinicians. The issue of early infective endocarditis detection is topical, since the mortality rate of this pathological condition is high; also, along with the classic symptoms of the disease, its atypical manifestations, so-called «masks» of infective endocarditis, often occur.

Objectives. The purpose of the work is to investigate one of infective endocarditis manifestations in the form of monoarthritis on the clinical case basis.

Materials and methods. The medical history, the laboratory and instrumental findings, Guidelines for the management of infective endocarditis 2015; Infective Endocarditis in Adults: Diagnosis, Antimicrobial Therapy, and Management of Complications, AHA 2015 (including update 2016).

Results. The patient, born in 1952, complains of the right foot pain, fever with chills, general weakness. Considers herself ill for 3 weeks. In connection with the right foot pain intensification, the patient was taken to a multidisciplinary hospital by the ambulance team and hospitalized to the therapeutic department. The anamnesis vitae is notable for her undergoing a procedure for curettage of the uterine cavity for an endometrial polyp half a year before the admission. The main diagnosis: Active mitral valve endocarditis due to Streptococcus haemolyticus. Mitral valve regurgitation stage III. Chronic coronary syndrome. Heart failure with preserved ejection fraction (EF 68 %). NYHA class II. Concomitant diagnosis: Mild anemia. Reactive arthritis. Deforming osteoarthrosis of the ankle joint. The treatment included: meronem 1 g 3 times daily intravenously (IV) and linezolidine 600 mg 2 times a day per os during 4 weeks; detoxification, cardiotropic, antiplatelet and anticoagulant therapy; proton pump inhibitors, diuretics, antifungal drugs.

Conclusion. Diagnosis of infective endocarditis is very challenging despite the presence of the specially developed diagnostic criteria. Given the polymorphic clinical manifestations of the disease and multiple organ damage, clinicians should be wary of the presence of infective endocarditis in patients with corresponding risk factors.

KEY WORDS: infective endocarditis, clinical diagnosis, arthritis

INTRODUCTION

The purpose of the work is to investigate one of the manifestations of IE in the form of monoarthritis on the basis of the clinical case.

MATERIALS AND METHODS

The medical history, the laboratory and instrumental findings, Guidelines for the management recommendations of infective endocarditis 2015; Infective Endocarditis in Adults: Diagnosis, Antimicrobial Therapy, and Management of Complications, AHA 2015 (including update 2016).

RESULTS

Patient O., 67 years old. Upon admission to the hospital complained of pain in the right foot, due to which the patient couldn’t stand;
increase in body temperature up to 40º C with chills, general weakness.

**Anamnesis morbi.** Considers herself ill for the past 3 weeks. About 2 weeks ago, she noticed a periodic increase in body temperature up to 40º C during the week, which was accompanied by chills; there was a sharp pain in the ankle joint of the right leg. She was taking paracetamol at the dose of 500 mg 2 times a day; as a result, the temperature was being decreased for a while. 05.11.19 due to intensification of the foot pain the patient called for an ambulance team. She was admitted to the Municipal non-commercial enterprise «Municipal clinical multidisciplinary hospital № 17» of Kharkov City Council and hospitalized to the therapeutic department.

**Anamnesis vitae.** According to the patient, about 6 months ago she underwent a procedure for curettage of the uterine cavity for an endometrial polyp. Before the first complaints appeared, she had led an active lifestyle, went in for sports (running, skiing). She disclaims pernicious habits, any allergic reactions. Denies hepatitis A, tuberculosis, sexually transmitted diseases. She also negates visiting places for curettage of the uterine cavity. She disclaims travel to infected regions due to severe pain in the right foot. Weight – 62 kg, height – 167 cm, BMI – 22, 23 kg/m². Body temperature is 37.3º C. Skin is somewhat pale, clean, dry. Mucous membranes are pale pink, clean, dry. Mucous membranes are pale pink, clean, dry. Swelling of the right foot is observed, palpation of the foot is sharply painful. Peripheral lymph nodes are not palpable. Thyroid gland is not enlarged on palpation.

**Objective examination.** General condition is stable. Consciousness is clear, posture is restricted due to severe pain in the right foot. Weight – 62 kg, height – 167 cm, BMI – 22, 23 kg/m². Body temperature is 37.3º C. Skin is somewhat pale, clean, dry. Mucous membranes are pale pink, clean, wet. Swelling of the right foot is noticed, palpation of the foot is sharply painful. Peripheral lymph nodes are not palpable. Thyroid gland is not enlarged on palpation.

**Respiratory system:** rhythmical breathing. Respiratory rate is 17/min. On percussion, above both lungs, percussion sound is clear. On auscultation, there is vesicular breathing in the lungs, no adventitious lung sounds.

**Cardiovascular system:** the apical impulse is determined in the V intercostal space 1.5 cm medially from the left mideclavicular line, of moderate strength, with an area of about 2 cm². The borders of relative cardiac dullness are not extended. Heart rate (HR) – 82 bpm. Ps – 82 bpm, rhythmic, unstressed, of satisfactory filling, the same on the right and left hands. On auscultation, heart sounds are rhythmic, muffled tones are noted. Blood pressure (BP): on the right arm – 130/80 mm Hg, on the left arm – 135/84 mm Hg.

**Gastrointestinal system:** The tongue is wet, clean. Abdomen is symmetrical, participates in breathing actively. On superficial and deep palpation, the abdomen is soft, painless. The lower edge of the liver is smooth, painless, palpated at the level of the right costal arch. Spleen, kidneys are not palpable. Tapping sign is negative on both sides. Stool and diuresis are not changed.

**Laboratory and instrumental tests.** The results of laboratory and instrumental studies allowed to reveal: mild anemia, an increase in ESR up to 65 mm/h, leukocytosis with a shift in the leukocyte formula to the left with the appearance of young forms, toxic granulation of neutrophils; increased level of C-reactive protein up to 204 mg/l; normal values of anti-streptolysin O, rheumatoid factor and seromucoids. According to the results of the three sets of blood cultures taken at 30-min intervals, the growth of *Streptococcus haemoliticus spp.* was obtained with the scale of sensitivity to antibacterial drugs.

**Echocardiography:** at the bottom of the medial mitral valve (MV) commissure, a threadlike formation of up to 1.5 cm in length was detected. Vegetation. Defect of the MV leaflet. Low degree dilatation of the left atrium cavity. MV regurgitation stage III. Ejection fraction (EF) 68 %.

**Chest X-ray:** without focal and infiltrative changes.

**X-ray of the right foot in two projections:** signs of deforming osteoarthrosis.

**The main diagnosis:** Active mitral valve endocarditis due to *Streptococcus haemoliticus.* Mitral valve regurgitation stage III. Chronic coronary syndrome. Heart failure with preserved ejection fraction (EF 68 %). NYHA class II.

**Concomitant diagnosis:** Mild anemia. Reactive arthritis. Deforming osteoarthrosis of the ankle joint.

Our patient received antibiotic therapy (meropenem 1 g 3 times daily IV, linezolidine 600 mg 2 times daily per os) for 4 weeks, as well as detoxification, cardiotropic, antiplatelet and anticoagulant therapy. Among the side effects during the treatment dizziness was noted. As a result of the therapy, the general condition of the patient improved: body temperature returned to normal, pain in the right foot decreased significantly – the patient moved independently with the help of walkers; there was also a decrease in the level of C-reactive
protein up to 2.9 mg/l, a decrease in the level of white blood cells and ESR; the three sets of blood culture 4 weeks after the start of treatment did not reveal the growth of microorganisms. Being discharged from the hospital, the patient was sent to the Heart Institute for surgical treatment.

**DISCUSSION**

IE is a rare infectious (mainly bacterial) disease that affects endocardium. IE risk factors are diverse. In developing countries, the most common condition predisposing to the occurrence of IE is rheumatic heart disease [3]. Due to the significant prevalence of artificial heart valve and cardioverter-defibrillators implantation, the latter contributes to an increase in the proportion of IE cases [4]. Mitral valve prolapse is also considered to be the predominant predisposing structural heart anomaly in developed countries [5]. Other risk factors include injecting drug use and human immunodeficiency virus infection [2]. Procedures associated with an increased IE risk comprise manipulations of the gums and periapical region of the teeth, as well as perforation of the oral mucosa, and the use of dental implants [6].

In 80% of cases, streptococci and staphylococci are the causative agents of IE [7], however, recently the proportion of these microorganisms among all pathogens has changed. So, the percentage of Staphylococcus aureus and coagulase-negative staphylococci prevalence increased [8; 9; 10], while the percentage of IE caused by streptococci of viridans group decreased [10; 17]. In addition, enterococci are the third among the leading causes of IE [11]. In about 10% of IE cases, blood culture results are negative, mainly due to the use of antibacterial drugs during some time before the examination [7].

Typical clinical manifestations of IE in 90% are common symptoms of fever with chills, decreased appetite and body weight. In 85% of patients, cardiac murmurs are heard. Up to 25% of patients suffer from embolic complications at the time of diagnosis [12]. The classic signs of IE are: Osler nodes (dense painful subcutaneous red nodules on the fingertips), Janeway lesions (small erythematous spots in the palms and soles), Lukin-Libman spots (hemorrhagic rashes on the skin, mucous membranes, conjunctival hemorrhages (spots), retinal hemorrhage), petechiae. In approximately half of IE cases, at least one of these symptoms occurs [13].

Given the multiple organ damage by a systemic infectious process, there is a polymorphic clinical picture of IE, and, consequently, late diagnosis of the disease in view of the low alertness of medical personnel regarding IE. Such «masks» of the pathologic process are pulmonary (in 20–90% of patients), neurological (5–10% of patients), rheumatologic (2–4% of patients), renal (3.5–4.8% of patients), cardiological (2–4% of patients), vascular (1.2–3% of patients), hematological (1.6–2.2% of patients), «acute abdomen» (0.5–1.5% of patients), ocular (0.3–0.5% of patients) [14].

Due to the activation of immune mechanisms that damage blood vessels in IE, a clinical picture that resembles that of systemic diseases of the connective tissue may develop, which requires differential diagnosis with those. One of IE «masks» is arthritis, the onset of symptoms of which can precede the classic picture of the disease for several months. «Rheumatic» manifestation of IE is observed in approximately 5–9% of patients, that is usually seen in its subacute course [14]. Most often, the knee and hip joints are affected [15]. In subacute bacterial endocarditis, the damage of musculoskeletal system by the pathogen usually manifests with symptoms of acute septic asymmetric arthritis involving 1–3 joints [16].

**CONCLUSIONS**

Despite the developed criteria, the diagnosis of IE is still a difficult task, which is associated with the polymorphism of the clinical picture and multiple organ damage as a result of the generalized infectious process.

Вступ. Діагностика інфекційного ендокардиту є важким завданням для лікарів-клініцистів. Проблема раннього виявлення інфекційного ендокардиту стоїть гостро через високий рівень смертності від цього патологічного стану; до того ж, поряд із класичними симптомами захворювання мають місце атипів його проявів, так звані «маски» інфекційного ендокардиту.

Мета роботи. На підставі клінічного випадку розглянути один із варіантів маніфестації інфекційного ендокардиту у вигляді моноартриту.

АРТРИТ ЯК МАНИФЕСТАЦІЯ ІНФЕКЦІЙНОГО ЕНДОКАРДИТУ

Уварова К. Г.
Матеріали та методи. Дані амнезу, лабораторно-інструментального обстеження, Рекомендації Guidelines for the management of infective endocarditis 2015; Infective Endocarditis in Adults: Diagnosis, Antimicrobial Therapy, and Management of Complications, AHA 2015 (including update 2016).

Результати. Пацієнка, 1952 р. н., скаржиться на біль у правій стопі, лихоманку з ознобом, загальну слабкість. Вважає себе хворою протягом 3 тижнів. У зв'язку з посиленням болю у стопі хвора бригадою швидкої медичної допомоги була доставлена до багатопрофільного стаціонару і госпіталізована до терапевтичного відділення. Амнезія життя заслуговує на увагу тому, що за піврік до надходження до стаціонару хворій було проведено процедуру кюретажу порожнини матки з метою видалення поліпа ендометрію. Був виставлений основний діагноз: Активний бактеріальний ендокардит митрального клапану, викликаний Streptococcus haemolyticus. Мітральна регургітація ІІІ ст. Хронічний коронарний синдром. Серцева недостатність зі збереженою функцією лівого шлуночка (фракція викиду 68 %). NYHA клас ІІ. Супутній діагноз: Анемія легкого ступеня. Реактивний артрит. Деформуючий остеоартроз голеностопного сустава. Проведена терапія включала: меронем 1 г 3 рази на добу в/в крапельно і лінезолідін 600 мг 2 рази в день per os протягом 4 тижнів; інгібітори протонної помпи, діуретики, протигрибкові препарати.

Висновки. Діагностика інфекційного ендокардиту складає велики труднощі, незважаючи на наявність спеціально розроблених діагностичних критеріїв. З огляду на поліморфізм клінічних проявів захворювання і поліорганність ураження, лікарям слід бути пильними щодо наявності інфекційного ендокардиту у пацієнтів з відповідними факторами ризику.

АРТРИТ КАК МАНИФЕСТАЦИЯ ИНФЕКЦИОННОГО ЭНДОКАРДИТА

Уварова К. Г.

Введение. Диагностика инфекционного эндокардита является трудной задачей для врачей-клиницистов. Проблема раннего выявления инфекционного эндокардита стоит остро из-за высокого уровня смертности от данного патологического состояния; к тому же, наряду с классическими симптомами заболевания имеют место атипичные его проявления, так называемые «маски» инфекционного эндокардита.

Цель работы. На основании клинического случая рассмотреть один из вариантов манифестации инфекционного эндокардита в виде моноартрита.

Материалы и методы. Данные амнеза, лабораторно-инструментального обследования, Рекомендации Guidelines for the management of infective endocarditis 2015; Infective Endocarditis in Adults: Diagnosis, Antimicrobial Therapy, and Management of Complications, AHA 2015 (including update 2016).

Результаты. Паціентка, 1952 р. н., предъявляет жалобы на боль в правой стопе, лихорадку с ознобом, общую слабость. Считает себя больной в течение 3 недель. В связи с усилением боли в стопе больная бригадой скорой медицинской помощи была доставлена в многопрофильный стационар и госпитализирована в терапевтическое отделение. Анамнез жизни примечателен тем, что за полгода до госпитализации больная бригадой скорой медицинской помощи была доставлена в многопрофильный стационар и госпитализирована в терапевтическое отделение. Анамнез жизни примечателен тем, что за полгода до госпитализации больная бригадой скорой медицинской помощи была доставлена в многопрофильный стационар и госпитализирована в терапевтическое отделение. Анамнез жизни примечателен тем, что за полгода до госпитализации.
настороженными в отношении инфекционного эндокардита у пациентов с соответствующими факторами риска.
