Abstract We show that general relativity coupled to a quantum field theory generically leads to non-local effects in the matter sector. These non-local effects can be described by non-local higher dimensional operators which remarkably have an approximate shift symmetry. When applied to inflationary models, our results imply that small non-Gaussianities are a generic feature of models based on general relativity coupled to matter fields. However, these effects are too small to be observable in the cosmic microwave background.

1 Introduction

A century after the introduction of general relativity by Einstein, finding a quantum mechanical description of general relativity remains one of the holy grails of theoretical physics and one of the few unresolved problems in modern physics. At this stage of our understanding of nature, it is not clear whether the quantization of general relativity is so difficult because of technical issues, essentially having to deal with a dimensionful coupling constant which is the Planck mass or whether general relativity or quantum mechanics need to be modified at very short distances. Given the current state of the art, it is important to investigate general relativity and quantum mechanics in the energy region where we expect them to work, i.e., below the Planck mass $M_P = 1/\sqrt{G_N}$. The concept of effective field theory provides a very powerful framework to investigate the quantization of general relativity in this energy regime, i.e. below the Planck mass. Effective field theory methods are powerful tools to deal with quantum gravity below the Planck mass [1–7].

An important question is to identify the energy scale at which the effective theory might break down. A well-established criterion is that of perturbative unitarity. Treating general relativity as an effective field theory, several groups have investigated the gravitational scattering of fields studying whether perturbative unitarity could be violated below the Planck scale [7–13]. It was shown in [9] that in linearized general relativity with a Minkowski background perturbative unitarity is restored by resumming an infinite series of matter loops on a graviton line in the large $N$ limit, where $N = N_s + 3N_f + 12N_V$ ($N_s$, $N_f$ and $N_V$ are, respectively, the number of real scalar fields, fermions and spin 1 fields in the model), while keeping $NG_N$ small. This large $N$ resummation leads to a resummed graviton propagator given by

$$iD^{\alpha\beta,\mu\nu}(q^2) = \frac{i(L^{a\mu}L^{b\nu} + L^{a\nu}L^{b\mu} - L^{a\beta}L^{\mu\nu})}{2q^2 \left( 1 - \frac{N\alpha\beta}{12\mu\nu} \log \left( -\frac{q^2}{\mu^2} \right) \right)} \quad (1)$$

with $L^{\mu\nu}(q) = q^{\mu\nu} - q^\mu q^\nu / q^2$. $N = N_s + 3N_f + 12N_V$. Note that in the standard model of particle physics $N = 283$. It is thus a large number which justifies our calculation. This resummation is valid for energies $E < 1/\sqrt{G_N}$. In the case, graviton loops are suppressed by factors of $N$ compared to matter loops and we do not need to worry about quantum gravity corrections. A similar calculation has been done by the authors of [8] who have pointed out that the denominator of this resummed propagator has a pair of complex poles which lead to acausal effects (see also [14, 15] for earlier work in the same direction and where essentially the same conclusion was reached). These acausal effects should become appreciable at energies near $(G_N N)^{-1/2}$. Thus, unitarity is restored but at the price of non-causality. We shall see that causality can be restored as well by replacing the log term by an interpolating non-local function. However, this procedure does not remove the poles which can be interpreted as black hole precursors [16] and correspond to the energy scale at which strong gravitational effects become important and thus the energy scale at which the effective field theory treatment of general relativity should break down. Note that this scale depends on the number of fields in the theory. Studying
quantum effects in general relativity in the large $N$ limit is not new and has been considered as well by e.g. Smolin [17] and Tomboulis [14,15].

Thought experiments based on general relativity and quantum mechanics [18–21] lead to the conclusion that distances smaller than the Planck length are not observable. These results can be interpreted as a form of non-locality around the Planck scale. The results obtained in [16] are thus not very surprising. The position of the poles define the energy scale at which the effective theory should break down and the non-local effects correspond to the minimal length expected around the mass scale of the first quantum black holes which are extended objects of the size of the inverse of the Planck mass.

The consequences of these non-local effects for the FLRW metric have been investigated in [22]. The aim of the paper is to derive an effective field theory for a scalar field, such as the inflaton, coupled to general relativity. We will show that this gives rise to some non-local effects in the interactions of this scalar field. These results only assume linearized general relativity and quantum field theory and are as such non-speculative.

2 Effective theory and non-locality

The tree-level gravitational scattering of two scalars has been considered already [23]. The invariant amplitude is given by

$$A_{\text{tree}} = 16\pi G \left( m^4 \left( \frac{1}{s} + \frac{1}{t} + \frac{1}{u} \right) + \frac{1}{2s} (2m^2 + t)(2m^2 + u) \right)$$

without $s = -(p_1 + q_1)^2 = (p_2 + q_2)^2$, $t = -(p_1 - p_2)^2 = (q_1 - q_2)^2$, and $u = -(p_1 - q_2)^2 = (p_2 - q_1)^2$. Note that we are using the signature $(+, -,-, -)$. It is straightforward to calculate the dressed amplitude using the resummed graviton propagator (1). Let us rewrite

$$i D^{\alpha\beta,\mu\nu}(q^2) = \frac{P^{\alpha\beta,\mu\nu}(q^2)}{1 + f(q^2)},$$

where $P^{\alpha\beta,\mu\nu}(q^2)$ is the usual graviton propagator and where $f(q^2)$ is given by

$$f(q^2) = -\frac{NG_N q^2}{120\pi} \log \left( -\frac{q^2}{\mu^2} \right).$$

The dressed amplitude is then given by

$$A_{\text{dressed}} = 16\pi G \left( m^4 \left( \frac{1}{s(1 + f(s))} + \frac{1}{t(1 + f(t))} \right) + \frac{1}{u(1 + f(u))} \right)$$

$$+ \frac{1}{2s(1 + f(s))} (2m^2 + t)(2m^2 + u)$$

$$+ \frac{1}{2t(1 + f(t))} (2m^2 + s)(2m^2 + u)$$

$$+ \frac{1}{2u(1 + f(u))} (2m^2 + s)(2m^2 + t).$$

We emphasize that this calculation is done in linearized general relativity with a Minkowski background treating general relativity as an effective theory that is valid at energies smaller than the Planck scale.

We can now Taylor expand this amplitude around the massive pole of the dressed propagator and obtain

$$A_{\text{dressed}} = A_{\text{tree}} + A^{(1)} + \cdots$$

with

$$A^{(1)} = \frac{2}{15} G^2 N \left( \frac{m^4}{s t} \log \left( -\frac{st u}{\mu^6} \right) \right)$$

$$+ \log \left( -\frac{s}{\mu^2} \right) \left( 2m^2 + t \right) (2m^2 + u)$$

$$+ \log \left( -\frac{t}{\mu^2} \right) \left( 2m^2 + s \right) (2m^2 + u)$$

$$+ \log \left( -\frac{u}{\mu^2} \right) \left( 2m^2 + s \right) (2m^2 + t).$$

It is easy to see that $A^{(1)}$ can be obtained from the following non-local dimension 8 effective operator $O_8$:

$$O_8 = \frac{2}{15} G^2 N \left( \partial_\nu \phi(x) \partial^\mu \phi(x) - m^2 \phi(x)^2 \right) \log \left( -\frac{\Box}{\mu^2} \right)$$

$$\times \left( \partial_\nu \phi(x) \partial^\mu \phi(x) - m^2 \phi(x)^2 \right),$$

where $\Box = g^{\mu\nu} \partial_\mu \partial_\nu$.

As mentioned before, the resummed graviton propagator (1) has a pair of complex poles which lead to acausal effects. We are expanding the effective action around these poles. The situation is very similar to that observed in [22]. The effective operator cannot be used to generate causal effects in the equations of motion as the Feynman propagators involve both advanced and retarded solutions. This is appropriate for scattering amplitudes but not for the equations of motion. There is a well-established procedure to ensure that the effective operator leads to causal effect at the level of the equations of motion. We follow the procedure outlined in [22,24] to generate a causal action (see also [25–28] for earlier works in that direction). This requires a reinterpretation of the log-term which can be interpreted as an interpolating non-local function of the type $\mathcal{L}(x, y)$. We consider the following action:

$$S = \int d^4x \sqrt{-g}$$

$$\times \left( \frac{1}{16\pi G_N} R(x) - \frac{1}{2} \partial_\mu \phi(x) \partial^\mu \phi(x) + \frac{m^2}{2} \phi^2(x) \right)$$
where the log term is interpreted as an interpolating function,
\[ S = \int d^4x \sqrt{-g} \]
\[ \times \left( \frac{1}{16\pi G_N} R - \frac{1}{2} \partial_\mu \phi(x) \partial^\mu \phi(x) + \frac{m^2}{2} \phi^2 + \frac{2}{15} G_N^2 N \right) \]
\[ \times \left( \partial_\mu \phi(x) \partial^\nu \phi(x) + m^2 \phi^2 \right) \int d^4y \sqrt{-g(y)} \]
\[ \times \left( x \log \left( \frac{-\Box}{\mu^2} \right) y \right) \partial_\nu \phi(y) \partial^\nu \phi(y) - m^2 \phi(2y) \right) \right). \]

Let us define the interpolating function by
\[ \mathcal{L}(x, y) = \left\{ x \log \left( \frac{-\Box}{\mu^2} \right) y \right\} \]
\[ \text{(11)} \]

The specific form for \( \mathcal{L}(x, y) \) depends on the system to which we want to apply this effective theory. It is straightforward to find a specific representation for a flat Minkowski background. One can use the following approximation valid for small \( \epsilon \): \( \log(x) \approx -1/\epsilon + x^2/\epsilon \). One then finds [24]
\[ \sim -1/\epsilon \delta(x - y) - \frac{8\pi^2}{\mu^2} \frac{1}{|x - y|^{4+2\epsilon}} \]
\[ \text{(12)} \]
where \( J_1 \) is the Bessel function. We see that \( \mathcal{L}(x, y) \) is a function of \( x - y \). For a purely time dependent problem in curved space-time (i.e. in cosmology), \( \mathcal{L}(x, y) \) takes the form
\[ \mathcal{L}(t, t') = -2 \lim_{\epsilon \to 0} \left( \frac{\Theta(t - t' - \epsilon)}{t - t'} + \delta(t - t')(\log(\mu \epsilon) + \gamma) \right) \]
\[ \text{(13)} \]
which is the appropriate form for the in–in formalism [22].

Before applying these results to cosmology, let us emphasize an important point. The amplitude in Eq. (7) is calculated in the approximation described above (i.e. large \( N \) while keeping \( N G_N \) small) in Minkowski space-time. We then proceed to identify the effective higher dimensional operator which can reproduce Eq. (7). We derive that the operator given in Eq. (8) when taking a Minkowski metric reproduces the amplitude given in Eq. (7). This enables us to calculate the coefficient of \( O_8 \) by matching it with our perturbative calculation. At this stage the coefficient of \( O_8 \) is uniquely determined and we can also use \( O_8 \) in curved space-time and hence for inflation calculations as well.

In this section, we have shown that the non-locality induced in the resummed graviton propagator leads to non-locality in the self-interactions of a scalar field coupled to graviton. The same would be true of any spin state as well. Non-locality is an intrinsic feature of a quantum mechanical description of general relativity as emphasized in the introduction. Note that remarkably, the higher dimensional scalar field operator obtained by integrating out the poles (quantum black holes) in the graviton propagator, are invariant under approximative shift symmetry (\( \phi \to \phi + c \), where \( c \) is a constant) in the limit of the mass of the scalar field going to zero. The breaking of this shift symmetry is proportional to the mass of the scalar field. If we apply this construction to an inflation scenario as we shall do below, this implies that any contribution to the flatness of the potential will be suppressed by powers of \( m_s/M_p \) where \( m_s \) is the inflaton mass, which is of the order of \( 10^9 \) GeV. Quantum gravitational effects arising from quantum black holes are thus small and cannot affect the flatness of the potential. A potential for the scalar field may lead to breaking of the shift symmetry; however, one of our main points is that such a symmetry breaking will not be generated by quantum effects in general relativity if not introduced explicitly in the model. We shall now consider non-local effects due to the dimension 8 operator introduced in this section. We stress that this operator is an intrinsic feature of general relativity and scalar fields coupled to gravity.

3 Bounds from cosmic microwave background

We can now study the implications of this non-local effect, which is purely obtained by considering quantum field theory coupled to general relativity. These effects will be imprinted on the CMB as a deviation in the speed of sound. Focussing on \( O_8 \), we consider the \( x \)-dependent Lagrangian for an inflaton,
\[ L(x) = X + \frac{m^2}{2} \phi^2(x) + \frac{8}{15} G_N^2 N X(x) \]
\[ \times \left( X(y) + \frac{m^2}{2} \phi^2(y) \right) \]
\[ \text{(14)} \]
where we have introduced the standard notation \( X(x) = -1/2 \partial_\mu \phi(x) \partial^\mu \phi(x) \) and \( X(y) = -1/2 \partial_\mu \phi(y) \partial^\mu \phi(y) \). Remarkably, our calculation does not depend on the specific form of \( \mathcal{L}(x, y) \); we shall merely require that \( \int d^4y \sqrt{-g(y)} \mathcal{L}(x, y) \delta(x - y) = 1 \). The speed of sound can be calculated using the standard procedure [29]; since \( L(x) \) is a polynomial in \( X \), keeping in mind that \( dX(x)/dX(x) = \delta(x - y), \) we find
\[ c_s^2 = \frac{L(x)X(x)}{L(x)X(x) + 2X(x)L(x)X(x)} \]
\[ \approx 1 - \frac{32}{15}X(x)G_N^2N, \]
which remarkably does not depend on the specific representation chosen for \( L(x, y) \) to leading order in the \( \sqrt{G_N} \) expansion. Restricting ourselves to a spatially homogeneous scalar field, we get
\[ c_s \approx 1 - \frac{8}{15}\phi^2G_N^2N \]
\[ \approx 1 - \frac{2}{15\pi}H^2\epsilon G_N N, \]
where \( H \) is the Hubble parameter, \( \epsilon = 1/(16\pi G_N)1/V^2 (\partial V/\partial\phi)^2 \) is the slow roll parameter (the slow roll condition is that \( \epsilon \ll 1 \)) and where we have used the approximation \( X \approx XL_X \). Quantum effects in general relativity thus lead to a speed of sound which is not exactly one but close to it. This is a generic feature of general relativity coupled to scalar fields naturally leads to non-local effects. This non-locality can be associated with the existence of black hole precursors or quantum black holes [16]. We have shown that general relativity coupled to scalar fields can be quantized the usual way to leading order in the slow roll expansion. Restricting ourselves to a spatially homogeneous background [30].
