Abstract Azobenzene based metal ion-imprinted polymers (IIPs) were synthesized for selective separation of Co(II) and Cu(II) ions from the mixture of metal ions. After polymerization, cavities for the Co2+ and Cu2+ ions were created in the polymer materials by leaching with hydrochloric acid solution. The synthesized IIPs were characterized by FT-IR, 1H NMR and elemental analysis. The competitive sorption studies were carried out to evaluate the selectivity of the target metal ions. Interestingly, the observed sorption capacity was pH dependent and maximum sorption was found to be 95.4 and 103.0 mg·g⁻¹ for Co-IIPs and Cu-IIPs at pH 5, respectively. It was observed that the IIPs showed good selectivity to Co(II) and Cu(II) ions in the presence of other bi and tri-valent metal ions in solution. Reused capacity was also checked for six times without a significant decrease in binding affinity for IIPs.

Keywords azobenzene, adsorption, ion imprinted polymers, selectivity, cobalt ion, copper ion, removal

Introduction

Due to high capability of molecular recognition, molecular imprinting technique is widely used for preparation of polymeric materials. Since molecular imprinting exhibits the shape and chemical memory of target molecules, molecular imprinted polymers (MIPs) are synthesized and reported. The formation of specific binding sites for a predetermined ligand is the essence of this method. During the polymerization, the “imprinting molecule” known as a template shows a significant role in the preparation of MIPs. Firstly, functional monomers and templates formed complexes in solution and a high degree of cross-linking agents will be fixed through polymerization. A molecular memory is introduced into the polymer in this way, which is called as molecular imprinting polymer with high capability and specificity of rebinding the analyte.

Ion-imprinted polymers (IIPs) are also very similar to MIPs, but they can detect the metal ions after imprinted maintaining all attributes of molecular imprinting polymers. The selectivity of the polymeric adsorbent in this IIPs process is based on the ligand specificity, on the coordination number and coordination geometry of the ions and also on the ions charges and size. Being outstanding advantages such as simple, convenient to prepare, high selectivity, IIP is used to selectivity of metal ions. One of the most important synthetic methods of IIP is surface ion imprinted technique.

For example, copper is a very important metal for industries, as well as biological essential element for human health. Furthermore, Cu(II) ion is also one of the major components of environmental pollution due to heavy metal ions such as Hg, Cd, Cr, Pb, etc. A new Pb2+-IIPs was reported based on the dual functional monomers of methacrylic acid and vinyl pyridine for selective solid-phase extraction (SPE) of Pb2+ in water samples. The IIPs-SPE demonstrated potential applications for rapid and high-effective clean-up and enrichment of trace Pb2+ ions in complicated matrices. Among many treatment technologies, adsorption is a popular technology due to simplicity. It is employed to mitigate the Cu(II) smerey problem with low cost and time-saving. Several works have been reported about adsorption of Cu(II), but the selectivity of adsorbents in application still needs to be improved.

As a part of vitamin B12, cobalt is an essential element for human health. Among heavy metals, cobalt is an oligo element. However, high concentrations of cobalt in human body may cause low blood pressure, diarrhoea, lung irritation, paralysis, and bone defects. Various methods such as adsorption, ion-exchange, extraction, membrane filtration and biological treatment have been used for Co(II) removal. Ion imprinting technology is an effective approach to preparation of imprinted adsorbents for dramatically enhancing binding and selectivity of ion or molecule and reused for many times.

Based on the literature review, we find that liquid-liquid extraction, co-precipitation and ion-exchange are the common and traditional methods for separation of Co and Cu. However, these methods often need large amounts of highly pure organic solvents, which are harmful to health and to be created environmental problems. Among them, SPE has paid an increasing attention in the separation of trace level of metal ions. In this point of view, reasonable and promising sorbents development is important based on new SPE is for accurate, rapid and quantitative measurement of trace metal. SPE offers several advantages such as SPE does not have the concerns with emulsion formation, it is less labor intensive, which can be attributed to the mechanism of the technique that allows the compound of interest to be extracted from the sample in a single loading step. Furthermore, SPE is more easily automated, which increases the potential to nearly eliminate manual labor. Finally, SPE is better suited to enriching the concentration of the target compounds in a given sample. However, IIPs are more selective than others due to it prepare by imprinted with desired ion or molecule.

In this current work, we have synthesized two novel IIPs such as Co-IIP and Cu-IIP containing azobenzene chromo-
A novel IIP is used for selective identification of Co and Cu from other transition and rare earth cations (Ni
2+, Zn
2+, Cd
2+, La
3+, Ce
3+, and Pr
3+, etc.) in divalent and trivalent solution mixture.

**Experimental**

**Materials**

4-Aminobenzoic acid (Fluka, Switzerland), sodium nitrite (BDH), phenol (Merck), acrylic acid, benzoyl peroxide, acetic acid, sodium hydroxide (Aldrich), hydrochloric acid, tetrahydrofuran (THF), ethylene glycol-dimethyl acrylate (EGDMA), benzyl peroxide (BPO), cobalt(II) chloride (Sigma-Aldrich), Cu(II) acetate (Sigma), nickel(II) chloride (Sigma-Aldrich), zinc(II) sulfate (BDH), cadmium(II) chloride (Aldrich), lanthanum(III) chloride (Sigma-Aldrich), cerium(III) chloride (Aldrich), and praseodymium(III) chloride (Sigma-Aldrich) were used as received. 1,3-Dicyclohexylcarbodiimide (DCC) (Fluka) and 4-(N,N-dimethylamino) pyridine (DMAP) (Fluka) were also used to progress the synthetic work. THF and dichloromethane were refluxed over calcium hydride (Fluka) and phosphorus pentoxide, respectively. The solvent was distilled out before use. Without further purification, the other solvents and chemicals were used as received.

**Instruments**

Perkin Elmer (670) spectrometer was used to record the FTIR spectra. 1H NMR (500 MHz) spectra were measured with a Bruker (DMX500) spectrometer. The morphology and composition of compounds (elements detection) were studied by field emission scanning microscopy (FESEM) and FESEM-EDX (JSM-7800F, FESEM, JEOL, USA), respectively. FE-SEM measurement was performed to study the morphology of IIPs. Sputter coating was applied for an ultra-thin coating of platinum onto a specimen. The absorbance measurements were performed by UV-vis spectrophotometer (UV-2600 Shimadzu). Metal ion concentrations were analyzed by ICP-MS (Agilent 7500 series). An Agilent (7500) instrument was used with the operating conditions: plasma gas flow rate 15 L·min
−1, auxiliary gas flow rate 1.0 L·min
−1, cooling water flow rate (RF/TP) 2.0 L·min
−1, ICP RF Power 1200 W, Interface pressure 350 Pa, Cooling water flow rate (WC/IF) 1.8 L·min
−1 and analyzer pressure 3×10
−4 Pa (no gas mode).

4-{[(E)-(4-hydroxyphenyl)diazenyl]benzoic acid (1)

The azo-based polymers compounds were synthesized as outlined in Scheme 1. 4-Aminobenzoic acid (2 g, 0.0182 mol) was placed into a 250 mL beaker and dissolved in a mixture of 100 mL of methanol and water (5 : 1 ratio). About 5 mL of hydrochloric acid (37%) was added and it was cooled to 2 °C with an ice bath. An aqueous solution of sodium nitrite (1.5 equivalents, 1.89 g in 10 mL) was added drop-wise and the mixture was stirred for 1 h. The mixture was transferred into 400 mL of MeOH with 100 mL distilled water (temp. maintained at 2 °C by ice bath) containing the phenol (1 equivalent, 1.717 g) and pH 9 was adjusted using 10% sodium hydroxide solution, which was further stirred for 4 h. Then, the mixture was poured in a beaker containing 800 mL water and the pH of the mixture was adjusted around 3 using HCl (10%). The resulting precipitate was collected by filtration. The product compound 1 was recrystallized twice using methanol to give a reddish colored solid with a yield of 68%. IR (KBr) νmax: 3429 (O—H stretch), 3283 (aromatic C—H stretch), 1681 (C=O stretch, acid), 1585 (aromatic C=C stretch), 1458 (N=O stretch), 1282 (C—O stretch cm
−1). 1H NMR (CDCl
3, (500 MHz)): 8.46 (dd, 4H, Ar—H), 8.08 (d, 2H, Ar—H), 7.97 (d, 2H, Ar—H), 9.40 (s, 1H, Ar—OH).

4-{[(E)-(4-(acryloyloxy)phenyl)diazenyl]benzoic acid (2)

In a round bottom flask, 250 mg of compound 1 (1.033 mmol) was dissolved with dry THF (5 mL) and dry CH
2Cl
2 (20 mL) with stirring. Then 1.2 equivalents (89 mg) of acrylic acid, 1.5 equivalents (319 mg) of DCC and 10 mg of DMAP were added and stirred continuously. The progress of the reaction was monitored with thin layer chromatography-silica gel plate (hexane and ethyl acetate ratio is 2 : 1). After stirring for 24 h, the product was extracted with CH
2Cl
2 with few drops of acetic acid and the product was washed with water at least three times. The solvent was removed by rotary evaporator and solid was dried in oven at 50 °C. Reddish yellow colour compound 2 (yield 58%) was obtained.

**Preparation of metal ion complexes**

4-{[(E)-(4-(acryloyloxy)phenyl)diazenyl]benzoic acid-cobalt (3a) or 4-{[(E)-(4-(acryloyloxy)phenyl)diazenyl]benzoic acid-copper (3b)

Briefly, in a 50 mL round bottom flask, 50 mg (0.176 mmol) of compound 2 was dissolved with anhydrous THF (10 mL) and then treated with 1 equivalent of metal salt Co(II) chloride or Cu(II) nitrate, as imprint metal ions, used separately at room temperature under continuous stirring for 12 h. At the end of this process, different color complexes were appeared (3a and 3b).

**Synthesis of Co(II) or Cu(II) ion-imprinted polymer (4a and 4b)**

The thermal polymerization technique was used to prepare the azo based imprinted polymers. The synthesis procedure of the Co-IIP and Cu-IIP preparation are illustrated in Scheme 1. After complexation (3a or 3b), THF containing 3a or 3b was added to a mixture of cross-linking agent EGDMA (1.0 g), benzoyl peroxide (40 mg) as an initiator and purge N
2 gas for 20 min to remove molecular O
2, which traps the radicals and
Adsorption-desorption of azo-based ion imprinted polymer

Batch experiments were applied to study the sorption and desorption of Co\(^{2+}\) and Cu\(^{2+}\) for azo-based ion imprinted polymer (M-IIPs) materials in aqueous solutions.

General procedure of batch adsorption

Exactly 100 mg of the imprinted polymers (5a or 5b in Scheme 1) was placed in a plastic container and then single metal ion solution of 20 mL (0.1 M) was added into 5a or 5b to appropriate pH (3—8) using sodium acetate buffer (20 mL) and shaking at 3 h with speed of 200 rpm with a shaker. After reaching equilibrium, the supernatant solution was collected by filtration and metal ions concentration was determined by ICP-OES. Perkin Elmer, optima 8300, ICP-OES tool was used for the measurements.

Adsorption-desorption on the IIPs

For this experiment, an aliquot of cobalt or copper solution (e.g., 20 mL of 50 mg·L\(^{-1}\)) was treated with 50.0 mg of IIPs at pH 3—8. The suspension was stirred for 6 h using a magnetic stirrer. The supernatant solution was collected by filtration and then single metal ion pre-concentrated onto IIPs materials were then eluted by 20 mL of M HCl in water during 12 h stirring. The suspensions were centrifuged and then eluent solutions containing Co\(^{2+}\) or Cu\(^{2+}\) ion were removed from the IIPs. The results Co\(^{2+}\) or Cu\(^{2+}\) ion contents of the solutions were determined by ICP-MS. Using Eq. (1), the percentage of metal ion adsorbed on the sorbent was determined, where \(C_i\) and \(C_0\) (mg·L\(^{-1}\)) are the concentrations of metal ions before and after extraction.

\[
\text{Absorption(\%) = } \frac{C_i - C_f}{C_i} \times 100
\]  
Eq. (2) can be used to calculate the metal ion adsorption.

\[
q_e = \frac{C_i - C_f}{m} \times V
\]  
where \(q_e\) is the adsorption amount (mg·g\(^{-1}\)), \(V\) is the volume of metal solution (L), \(m\) is the mass of polymeric ligand (g).

The distribution ratio, \(K_i\) (mL·g\(^{-1}\)) of metal ions between the M-IIPs and aqueous solution was also calculated by Eq. (3), where \(V\) is the volume of solution and \(m\) is mass of IIPs (mg).

\[
K_i = \left( \frac{C_i - C_f}{C_i} \right) \frac{V}{m}
\]  
Selectivity coefficients \(k\) for Co\(^{2+}\) or Cu\(^{2+}\) ion relative to foreign ions in the solution are defined as:

\[
K_{i\text{Cu}^{2+}} = \frac{k_{i\text{Co}^{2+}}}{k_{i\text{Cu}^{2+}}}
\]  
where, \(k_{i\text{Co}^{2+}}\) and \(k_{i\text{Cu}^{2+}}\) are the distribution ratios of Co\(^{2+}\) and foreign metal ions, respectively. Moreover, \(k_{i\text{Co}^{2+}}\) and \(k_{i\text{Cu}^{2+}}\) were used in Eq. (4) for measuring the selectivity coefficient \(k\) of Cu\(^{2+}\) ion relative to foreign ions in the solution, respectively.

Results and Discussion

Synthesis

An azo compound 4-[E]-[4-hydroxyphenyl]diazenyl]benzoic acid (1) was synthesized using 4-aminobenzoic acid as a starting material, which is undergone diazotization and coupling reaction with sodium nitrite and phenol under cooled temperature about 2 °C in acidic medium.

Compound 1 was recrystallized from ethanol, achieving a red color crystalline solid with yield of 68%. Further reaction with acrylic acid produced 4-[E]-[4-(acyloxyloxy)phenyl]diazenyl]-benzoic acid 2 by coupling reaction with DCC, 58% reddish yellow color compound. Then, compound 2 was treated with metal salts of Co and Cu ion, as imprint ion (2 batch method separately) under maintained continuous stirring at room temperature. Finally, the compounds appeared complex with different colors.

Then, the complex 3a or 3b formation was confirmed by using UV-vis spectroscopy technique. Then, thermal polymerization technique was used to synthesize the metal ions imprinted polymers (IIPs), which are referred to azoacid-based metal complex.

EGDMA was used as a cross-linker agent, and complex solution 3a—3b was added with benzoyl peroxide as an initiator, and the mixture was heated at 80 °C for 34 h. After polymerization, methanol was used to precipitate the product and the IPs was dried (4a—4b) at 50 °C with an oven. Then, the cobalt and copper ions were leached from polymer products (IIPs) with 20 mL HCl (2 M) solution through shaking for further adsorption of metal ions on the imprinted cavity polymers of 5a—5b separately. The details synthesis strategy of the Co-IIPs and Cu-IIPs preparation is depicted in Scheme 1.

Characterization

FT-IR spectra

The FT-IR spectra of azoacid-acrylate compound (2), azoacid-acrylate-Co-IIPs (4a) and azoacid-acrylate-Co-IIPs (5a) (leached) were obtained by using a KBr pellet method in Figure 1a. The similar IR spectra have been observed for the compounds of Cu-IIPs (4b) and Cu-IIPs (5b) (leached), but they have high intensity spectra. The backbone structures of all polymers are similar, so the similar characteristic peaks in IR spectra were observed. Those functional groups belong to polymers. For compound 2, the O—H stretching and bending vibrations of carboxyl groups are located at 3440, 3336 and 1639 cm\(^{-1}\), respectively. In addition, stretching vibrations of CH\(_2\) groups are 2955 and 2818 cm\(^{-1}\). The typical vibration absorptions are 1675 and 1630 cm\(^{-1}\) for carbonyl and vinyl functional group of acid compound 2. Moreover, the typical vibration absorption of benzene ring corresponds to 1581 and 1420 cm\(^{-1}\). Representative vibration of 1245 and 1150 cm\(^{-1}\) of the aryl ring–O vibration and phenyl–N stretching mode were clearly observed in the FTIR spectra of supported azo-molecule, additional O—H bending mode. The stretching vibrations responsible for C=O bonds are located at 1727 cm\(^{-1}\) for Co-IIPs (4a) and 1728 cm\(^{-1}\) for Cu-IIPs (4b), whereas asymmetric stretching vibrations of CH\(_2\) groups are 2955 cm\(^{-1}\) (\(\delta\)) due to polymerization, vinyl functional group at 3111 and 1630 cm\(^{-1}\) are absent in compounds 4a and 4b. In case of both leached polymers (Co-IIPs and Cu-IIPs), IR spectra are almost similar with corresponding unleached polymers (Co-IIPs and Cu-IIPs) in Figure 1.

Surface morphology analysis using FE-SEM

The scanning electron microscopy is a suitable tool to observe the surface morphology of IIPs. Field emission scanning electron microscopy (JEOL JSM-7800F) was used to observe the surface morphology of the IIPs. SEM micrographs were taken of samples after extraction of the template molecule to visualize their morphologies. FE-SEM images of Figure 2a
Figure 1 Comparison FTIR spectra for (a) azo acid-acrylate (1), azo acid-acrylate based Co-IIPs (4a) and azo acid-acrylate based Co-IIPs (leached) (5a); (b) azo acid-acrylate (1), azo acid-acrylate based Cu-IIPs (4b) and azo acid-acrylate based Cu-IIPs (leached) (5b).

shows for the synthesized azobenzene-acrylate compound 2. Figures 2b and 2c image are represented to the Co-IIPs 4a and Cu-IIPs 4b, respectively. An unsmooth surface of the compound (Figure 2a) was observed with an irregular spherical shape. This type of surface nature indicated that the compounds are forming structurally and purely in organic nature. On the other hand, the IIPs (Figures 2b and 2c) seem to porous microstructure and it was good agreement with other observations. [32]

EDX analysis for elemental evaluation

Electron dispersive X-ray spectroscopy (EDX) investigation was observed to know the quantitative presence of all in the synthesized IIPs samples of 4a and 4b. Figure 3a showed that the prepared compound was made up of C, N, O, and Co only. Their weight compositions were 38.05%, 5.97%, 51.23% and 4.75% for C, N, O, and Co, respectively, which is illustrated in Figure 3a inside the inset. The signals corresponding to C, N, O, and Co have been detected and the compound has no other element, meaning that it is purely azo based Co-IIPs. Different observation was found for Cu(II)-IIPs in Figure 3b due to different metals such as copper, which showed that the prepared compound was made up of C, N, O, and Cu only. Their weight compositions were 39.91%, 6.26%, 36.91% and 32.92% for C, N, O, and Cu, respectively, which is presented in Figure 3b inside the inset. It can be concluded that the prepared compound has no other element except purely Cu-IIPs.

Sorption and desorption

Effect of pH on the adsorption of metal ions

To evaluate the sorbent adsorption behavior and check the effect of pH, a series of pH values ranging from 3 to 8 were used and observed. Herein, pH was adjusted with the addition of sodium acetate buffer solution. The adsorption capacity
of Co (II) and Cu (II) ion on sorbents as a function of pH is shown in Figure 4. It was found that the adsorption of Co(II) and Cu(II) ions onto the Co and Cu ion imprinted polymers increases gradually upon increasing the pH from 3 to 5. Maximum recoveries of corresponding metal ions were at pH 5 and it was almost saturated over pH 6, which is representative in Figure 4. It is noted that there is no precipitate in the sample solution under the studied conditions. Moreover, Table 1 also represents the sorption capacity of the corresponding metal ions imprinted polymers over the studied pH ranges and showed the good agreement of the pH dependent ability of the both sorbents. A batch equilibrium method was used to estimate the adsorption behavior of the sorbent/ ligand towards different metals, using the complex form of selected metal ions (Co$^{2+}$ and Cu$^{2+}$). After batch equilibration, the complex formation of the COOH group (behave bidentate ligands) with the metal ions resulted in a four member stable ring complex. The metal ions are bound to both oxygen anions and the dative oxygen atoms, and the chelating complex 4a or 4b is represented in Scheme 1.

**Adsorption capacity**

The total amounts of ion adsorbed per gram of the sorbent materials are known as adsorption capacity ($Q$). For IIPs, adsorption capacity is an important indicator for the evaluation of the synthesized sorbent. Using the IIPs sorbent per gram can understand the maximum metal ions adsorbed. In order to evaluate the static adsorption capacity of Co(II) ion onto the Co(II)-IIP at 25 °C, 50 mg of leached IIPs sorbent was equilibrated with 20 mL of Co ion solutions possessing the concentration of 50 mg·L$^{-1}$ at optimal conditions. Same procedure was used to Cu(II)-IIPs due to evaluate the adsorption capacity of Cu(II) ion onto the IIPs at the studied conditions. Eq. (2) was used to calculate the adsorption capacity and the calculated values are revealed in Table 1 over the studied pH ranges. Due to the possibility of precipitation or hydroxide form of metal ions, higher values of pH were not considered here during the batch experiment. Table 1 represents the values of extraction yield of Co$^{2+}$ and Cu$^{2+}$ ions using azo polymers at studied pH. The effect of pH on the extraction yield (%) of Co$^{2+}$ or Cu$^{2+}$ ions using corresponding Co-IIPs or Cu-IIPs polymers is shown in Figure 5. It can be observed that the percentage of Co$^{2+}$ or Cu$^{2+}$ ions adsorption increased at higher pH values and mostly saturated at pH 6. Those ions (Co$^{2+}$ and Cu$^{2+}$) ions are quantitatively high extracted at pH 5. The sorption quantity is a little bit low due to the protonation of the binding sites of polymeric M-IIPs at the lower pH.
metal ion to be selectively extracted. It acts as either a hard or soft acid. The third key factor in selective extraction or separation is hydrogen ion concentration in metal ion solution.\[34-36\]

The obtained results are summarized in Table 2 at pH 5. It is clearly shown that the ion imprinting effect by comparing the obtained selectivity results is tabulated in Table 2.

Furthermore, the target ions are allowed to selective adsorption due to their cavities as specific holes in imprinted polymers. More specifically, the imprinted polymers with cavities have a definite shape and size of the template. It is difficult to absorb the substances with smaller or bigger size than the imprinted template. Due to molecular geometry, the prepared ion imprinted polymers such as Co(II)-IIPs and Cu(II)-IIPs showed excellent selectivity for the target molecules like Co(II) ions and Cu(II) ions, respectively. Considering the high selectivity coefficient values obtained by IIPs substances, an important difference between the binding of Co(II) or Cu(II) ions and others competitor ions to the imprinted sorbent can be clearly stated that the synthesized IIPs can be applied as a selective sorbent for recognition or separation of Co(II) and Cu(II) ions in the presence of other metal cations (di- and tri-valent) in various synthetic samples with different and complex matrices.

Zhang et al.\[36\] synthesized new Hg$^{2+}$-ion-imprinted polymers (IIPs) by a sol-gel process using the chelating agent dithizone and 3-aminopropyltriethoxysilane as a functional monomer for mercury speciation analysis in environmental and biological samples by solid-phase extraction (SPE) and atomic fluorescence spectroscopy (AFS) detection. A review work is reported on the current status and challenges of ion imprinting described various aspect such as fundamentals of IIPs preparation, principles of IIPs preparation, components of IIPs preparation, functional monomer and ligand, cross-linker, initiator and porogen, preparation technologies of IIPs and also applications of various IIPs.\[37\] Another review also reported on the molecular imprinting: perspective and applications. The review contains about fundamentals of MIPs, smart MIT for MIPs, ingenious MIT for MIPs, special strategies of MIT for MIPs and also applications of MIPs.\[38\]

A green IIP was reported on the three functional monomers of low-cost eco-friendly gelatin (G), 8-hydroxyquinoline (HQ) and chitosan (C), namely G-HQC IIPs, and were applied as an effective and recyclable adsorbent to remove Cu(II) from aqueous solution.\[39\] A new dummy molecularly imprinted polymer (DMIP) with propanamide as a dummy template molecule was reported for magnetic solid-phase extraction (MSPE) of acrylamide in biscuit samples, followed by high performance liquid chromatography (HPLC) determination.\[40\]

Qi et al.\[41\] synthesized a new three-dimensional (3D) origami IIP microfluidic paper-based chip device for specific, sensitive and multiplexed detection of Cu$^{2+}$ and Hg$^{2+}$ ions. In this device, the surface of the paper was activated by grafting with CdTe QDs through amino processing and formation of Cu$^{2+}$ or Hg$^{2+}$ IIPs and CdTe QDs complex that led to fluorescence quenching of QDs because the photo luminescent energy of QDs could be delivered to the complex. According to the report by Qi et al.,\[41\] the device can provide quantitative information and show further extension to the detection of other metal ions for environmental monitoring and food safety field. A multi-ion imprinted polymer (MIPs) embedded in a sol-gel matrix is reported by using Hg$^{2+}$, Cd$^{2+}$, Ni$^{2+}$ and Cu$^{2+}$ as templates and 3-aminopropyltriethoxysilane as a functional monomer and the dithizone coordination chemistry, which is enable to heavy metal removal and water pre-treatment.\[41\] Xu et al. reported on Hg$^{2+}$-IIPs based on the thymine-Hg$^{2+}$-thymine interactions for selective preconcentration of Hg$^{2+}$ in water samples.\[42\]

### Table 1 Sorption capacity at different pH with azo-based IIPs

| M-IIP | pH 3 | pH 4 | pH 5 | pH 6 | pH 3 | pH 4 | pH 5 | pH 6 |
|-------|------|------|------|------|------|------|------|------|
| Co-IIP | 87.8 | 90.4 | 95.4 | 95.2 | 78.2 | 80.1 | 82.0 | 81.9 |
| Cu-IIP | 92.9 | 98.5 | 103 | 103 | 71.5 | 78.9 | 82.7 | 82.1 |

### Table 2 Distribution ratio ($K_d$) and selectivity coefficient (k) values of specific Co-IIPs and Cu-IIPs at pH 5

| Cation | pH 5 | $K_d$ Co-IIP (mL·g$^{-1}$) | $K_d$ Cu-IIP (mL·g$^{-1}$) | k Co-IIP | k Cu-IIP |
|--------|------|--------------------------|--------------------------|---------|---------|
| Co$^{2+}$ | 91.2 | 17.9 | - | 4.1 |
| Cu$^{2+}$ | 11.4 | 96.0 | 7.9 | - |
| Ni$^{2+}$ | 16.8 | 18.2 | 5.4 | 5.2 |
| Zn$^{2+}$ | 12.8 | 11.6 | 7.0 | 8.2 |
| Cd$^{2+}$ | 16.1 | 20.2 | 5.6 | 4.7 |
| La$^{3+}$ | 3.1 | 5.6 | 28.9 | 16.9 |
| Ce$^{3+}$ | 7.2 | 3.7 | 12.6 | 25.5 |
| Pr$^{3+}$ | 4.9 | 5.0 | 18.3 | 19.0 |

Reusability of the azo-based Co-IIPs and Cu-IIPs sorbents

Reusability is an important phenomenon to evaluate the prepared polymers capability to use the sorbent in absorption-desorption processes without significant change under the optimum condition with several times. The Co$^{2+}$ ion adsorption-desorption procedure was repeated and carried out six times to test the reusability check of IIPs sorbents using the same sorbents. The same procedure was followed to check the Cu-IIPs reusability and regeneration for Cu$^{2+}$ ion. Sorbents were washed with 20 mL HCl (20%) for 2 h to remove the corresponding metal ions Co(II) and Cu(II) completely. Furthermore, deionized water was used to rinse the sorbents to neutralize the pH value. Before further extraction cycle continued, the sorbents were washed and dried under vacuum at 60 °C overnight followed by wash with deionized water.

### Conclusions

Two ion imprinted polymers Co-IIP and Cu-IIP were synthesized using respective metal ions and substituted azobenzene as a complexing agent in the presence of a cross-linking agent EGDMA, methyl acrylic acid used as functional monomer and benzoyl peroxide as an initiator. For recognition and separation of corresponding ions from its mixture, leaching was performed to remove the metal ions with 20% HCl solution from the template after the polymerization. The maximum sorption ability of the Co-IIPs and Cu-IIPs were found to be 95.4 and
103.0 mg·g$^{-1}$ of Co and Cu at pH 5, respectively. We also investigated the metal ions binding capacity using the imprinted and non-imprinted polymers and observed that the amount of metal ions bound in the case of imprinted polymer is higher than that of non-imprinted polymer. The binding of metal ions is dependent on pH, the adsorption values increase with increase in pH, and a saturation value is obtained at pH 5 to 6. The metal ion rebinding studies of Co(II) and Cu(II) ion imprinted polymers supported that Co(II) and Cu(II)-IIPs showed specific rebinding of Co(II) and Cu(II) ions, respectively. The Co(II) and Cu(II) ions are selectively bound from its mixture with presence of bivalent cations such as Ni(II), Zn(II), Cd(II) and trivalent cations such as La(III), Ce(III) and Pr(III) ions. The obtained results from the studied system proved the importance of tailoring metal ion imprinted system in the recognition and removal of metal ions from the mixture. The sorbent can be used to remove or separate Co(II) and Cu(II) ions in various agricultural products and water. Moreover, the obtain results would be very useful for human and environmental issue.
