Abstract

Background: Physical readiness for pregnancy potentially affects the new born's health status. The study aims to analyze pregnancy readiness in married female adolescents.

Methods: Data were collected in Probolinggo District, Indonesia from 2012-2014. This study involved 760 married female adolescents (< 20 years old) as the analysis units. There are 2 major ethnic groups in Probolinggo District (Javanese and Madurese), as well as a small number of other ethnic groups. The study's dependent variable was pregnancy readiness, while its independent variable was ethnicity. In addition, other independent variables were also analyzed, for example, marital status, age, education, and employment. The final analysis was done using a binary logistic regression. Pregnancy readiness variable was seen from other sub-variables, such as anemia status, body weight, stature, nutritional status, and mid-upper-arm circumference.

Results: Married female adolescents mostly suffered from anemia. The respondents mostly had normal anthropometry. Regarding pregnancy readiness variable, married female adolescents from all ethnicities married female adolescents were not ready to get pregnant. Madurese married female adolescents were 0.563 times readier to get pregnant compared to Javanese married female adolescents (OR 0.563; 95% CI 0.369-0.857). There was no significant difference between Madurese ethnic adolescents and the Java-Madurese ones and others. Moreover, there was no significant difference between educational levels and the respondents' readiness for pregnancy.

Conclusions: There were partial differences in readiness for pregnancy in married female adolescents from different ethnic groups married female adolescents. Madurese married female adolescents had a lower possibility of pregnancy readiness than Javanese ones.

Background

Early marriage still exists as part of traditional practices in several developing countries around the world, including Indonesia (1, 2). Many factors can affect it, for example, poverty and low educational levels (2–4). In general, early marriage has been associated with increased fertility and reduce the use of modern contraceptive, less frequent antenatal care, and unsafe delivery (5).

Early marriage is not only related to female adolescents’ health, but also their conception. Mostly, female adolescents are not ready enough to get married. Those who conceive need prime nutrition for their baby. Married female adolescents undernutrition will get worse during pregnancy. A malnourished woman is more likely to deliver a malnourished baby, causing the cycle of malnutrition from generation to generation (6, 7). Previous studies prove evidence that pregnancy in married female adolescents married female adolescents is a risk factor for early childhood development issues and stunting (5). married female adolescents also increases the risk of infant and child morbidity and mortality (8, 9).

In Indonesian, early marriage stems from the community’s religious and cultural beliefs (10, 11). According to Statistics Indonesia in 2015, the rate of early marriage in East Java was higher than the overall national rate, around 35%. The number of early marriage is distributed mainly in the northeast region of East Java province. The Probolinggo district has the highest rate of early marriage among other regencies/municipals of East Java (12). Previous research in this region reveals that 23% of reproductive-age women were underweight, 33% had anemia, and 15.7% were diagnosed with iron deficiency (13).

Based on the results of literature searching, previous research publications rarely analyze pregnancy readiness among married female adolescents from the aspects of physical readiness, anemia status and anthropometric status. Based on this reason, this study was aimed at analyzing pregnancy readiness among married female adolescents from different ethnic groups in Probolinggo, Indonesia.

Methods

Data Source

This study was conducted by collecting primary data in Probolinggo district, East Java, Indonesia. Data collection was carried out in a multi-round survey from 2012–2014. The study’s analysis unit was female adolescents (< 20 years) who were married. There were 2,493 newly married couples registered in nine selected sub-district offices of religious affairs between 2012 and 2014. Only non-pregnant women were enrolled to minimize the gestational effects on hemoglobin and anthropometric indices. Pregnancy testing was performed using the urinary-human chorionic gonadotropin (hCG) test kits from OneMed® products. The final sample size was 760 respondents that matched the inclusion criteria.

Data Analysis

This study firstly discusses about pregnancy readiness as the dependent variable married female adolescents. Pregnancy readiness was determined from anemia status seen from the levels of hemoglobin and anthropometric status. Anthropometric status consisted of body weight, stature, nutritional status based on body mass index (BMI), and mid-upper arm circumference (MUAC). Married female adolescents were considered ready to get pregnant if they do not suffer from anemia, underweight (≤ 40 kg), and, short stature (≤ 140 cm). Besides, they should have the MUAC of ≥ 23.5 cm.

The levels of hemoglobin were determined from capillary finger-prick blood samples drawn using HemoCue Hb 201 micro cuvettes and subsequently analyzed using a portable hemoglobin measurement kit, HemoCue® AB, from Anglehome, Sweden. Anemia was classified into four categories according to the WHO: mild anemia (hemoglobin level of 10-11.9 g/dL), moderate anemia (hemoglobin level of 7–10 g/dL), and severe anemia (hemoglobin level of < 7 g/dL) (14). Bodyweight was measured using a digital body scale Seca® type 803 with an increment of 100 g. Furthermore, body stature was measured using a microtoise with a 0.1 cm increment. BMI was calculated as a ratio of weight in kilograms and the square of height in meters (kg/m2). Age-specific BMI reference values for adolescence were used to evaluate the nutrition status of subjects aged 14–19 years (15). Underweight in adolescents was described as BMI with the standard deviations (SD) of < -2. Overweight in adolescents was described as BMI with the SD of > +2. Obesity in adolescents was described as
BMI with the SD of > + 3. Measurement of MUAC was performed using a fiber tape with a 0.1 cm increment. A cut-off point of < 23.5 cm denoted a risk for chronic energy deficiency (16). All anthropometric measurements were performed by well-trained field staffs.

Despite ethnicity, there were four other independent variables involved: marital status, age, education level, and employment status. Ethnicity consists of three categories: Javanese, Madurese, and others. Marital status consisted of two categories: first married and second marriage/more. Age was the age of female adolescents at the lastest marriage. Age was grouped into three groups: ≤ 15 years old, 16–17 years old, and ≥ 18 years old. Education level consisted of four levels: no school, elementary school, junior high school, senior high school, and higher. Employment status was categorized into two: unemployed and employed.

In the initial stage, a collinearity test was carried out to ensure whether there was no collinearity between variables. Because all variables were dichotomous, the next step was to use the chi-square test to select the dependent variable for the next testing stage. The nature of the dependent variable, in the final stage, utilized a binary logistic regression test to determine predictors of the nutritional status of married female adolescents. All statistical analyzes were carried out using SPSS 22 software.

Results

Table 1 shows the distribution of anemia status and anthropometric status among married female adolescents in Probolinggo district, Indonesia. The number of respondents with anemia was slightly greater than those without anemia. Those with normal body weight and normal stature were dominant. Most of the respondents had normal nutritional status and MUAC of ≥ 23.5 cm.

| Variable                          | n   | %   |
|-----------------------------------|-----|-----|
| Anemia status                     |     |     |
| Severe anemia                     | 27  | 3.6%|
| Moderate anemia                   | 77  | 10.1%|
| Mild anemia                       | 291 | 38.3%|
| Not anemia                        | 365 | 48.0%|
| Bodyweight                        |     |     |
| Low bodyweight                    | 116 | 15.3%|
| Normal bodyweight                 | 644 | 84.7%|
| Stature status                    |     |     |
| Short stature                     | 88  | 11.6%|
| Normal stature                    | 672 | 88.4%|
| Nutritional status                |     |     |
| Underweight                       | 227 | 29.9%|
| Normal weight                     | 463 | 60.9%|
| Overweight                        | 57  | 7.5% |
| Obese                             | 13  | 1.7% |
| Mid-upper-arm circumference       |     |     |
| < 23.5 cm                         | 264 | 34.7%|
| ≥ 23.5 cm                         | 496 | 65.3%|

In Table 2, the results of the collinearity test show that the tolerance value of all variables was greater than 0.10. While the VIF value for all variables was less than 10.00. The basis for decision making in the multicollinearity test concludes that there were no symptoms of multicollinearity in the regression model.

Tabel 2. Colinearity test results of the readiness to get pregnant among married adolescent girls and related variables in Probolinggo Regency, Indonesia (n = 760)
### Variables Collinearity Statistics

| Variables         | Tolerance | VIF |
|-------------------|-----------|-----|
| Ethnicity         | 0.985     | 1.016 |
| Marital type      | 0.978     | 1.023 |
| Age groups        | 0.939     | 1.065 |
| Education level   | 0.921     | 1.085 |
| Employment status | 0.983     | 1.017 |

**Dependent Variable: the readiness to get pregnant**

Besides, Table 3 shows the cross-tabulation of ethnicity, pregnancy readiness, and related variables. The respondents in all ethnic groups were mostly not ready to get pregnant. In all ethnicities, most of the respondents had the first marriage and were in the age group of ≥ 18, except for others ethnic dominated by those in the age group 16–17.

Tabel 3. Descriptive statistics of ethnicity, the readiness to get pregnant among married adolescent girls, and related variables in Probolinggo Regency, Indonesia (n = 760)

| Characteristics                  | Ethnicity |      |      |      |      |
|----------------------------------|-----------|------|------|------|------|
|                                  | Javanese  | Madurese | Others |
| Readiness to get pregnant        |           |      |      |      |      |
| Not ready                        | 287       | 71.4% | 159  | 81.1% | 119  | 73.5% |
| Ready                            | 115       | 28.6% | 37   | 18.9% | 43   | 26.5% |
| Marital type                     |           |      |      |      |      | 0.984 |
| First marriage (ref.)            | 376       | 93.5% | 183  | 93.4% | 152  | 93.8% |
| Second marriage/more             | 26        | 6.5%  | 13   | 6.6%  | 10   | 6.2%  |
| Age groups                       |           |      |      |      |      | 0.248 |
| ≤ 15 (ref.)                      | 10        | 2.5%  | 6    | 3.1%  | 9    | 5.6%  |
| 16–17                            | 191       | 47.5% | 85   | 43.4% | 80   | 49.4% |
| ≥ 18                             | 201       | 50.0% | 105  | 53.6% | 73   | 45.1% |
| Education level                  |           |      |      |      |      | **0.004** |
| No school                        | 46        | 11.4% | 27   | 13.8% | 7    | 4.3%  |
| Elementary school                | 141       | 35.1% | 53   | 27.0% | 46   | 28.4% |
| Junior high school               | 128       | 31.8% | 60   | 30.6% | 69   | 42.6% |
| Senior high school and higher    | 87        | 21.6% | 56   | 28.6% | 40   | 24.7% |
| Employment status                |           |      |      |      |      | 0.779 |
| Unemployed                       | 198       | 49.3% | 95   | 48.5% | 84   | 51.9% |
| Employed (ref.)                  | 204       | 50.7% | 101  | 51.5% | 78   | 48.1% |

Note: * p < 0.05; ** p < 0.01; ***p < 0.001.

Furthermore, Javanese respondents dominantly graduated from elementary school education. While Madurese and other respondents had junior high school education.

Based on employment status, Javanese and Madurese respondents were employed. While the respondents from other ethnic groups were dominantly unemployed.

Further results of the binary logistic regression test on pregnancy readiness are available in Table 4. There were two independent variables tested at this stage: ethnicity and education level.
The results of the analysis in Table 4 inform that Madurese married female adolescents were 0.563 times more likely to be ready for pregnancy than Javanese married female adolescents (OR 0.563; 95% CI 0.369–0.857). While no significant differences were found between the other ethnic groups and the Javanese group. Similarly, there were no significant differences between education levels.

Tabel 4. Binary logistic regression test results of the readiness to get pregnant among married adolescent girls in Probolinggo Regency, Indonesia (n = 760)

| Predictors                     | The readiness of Nutritional Status |
|-------------------------------|------------------------------------|
|                               | Slg. | OR        | Lower Bound | Upper Bound |

Discussion

Married female adolescents who are lack of pregnancy readiness are still found in some areas. The ongoing practice of early marriage (1)(10) and many reports on the high prevalence of anemic adolescents and nutritional status issues in young women (17–21) are two among other evidence in Indonesia (22).

The results of the analysis inform that Madurese married female adolescents were less likely to be ready for pregnancy than Java ethnic. The findings of this study reinforce the results of previous studies focusing on Madurese or areas dominated by Madurese ethnic group. Madurese in general still practice culture contrary to modern health practices (23, 24). For example, they adopt the different concept of family size and early marriage (25) and rarely utilize health services (26).

The 2018 Indonesian Public Health Development Index (IPHDI) released by the Indonesian Ministry of Health shows places regencies/municipalities dominated by Madurese are at the lowest rank of public health index. The five lowest ranked regions on the public health index in East Java Province are mostly inhabited by Madurese population (27). This ranking shift in East Java over the years has not changed much compared to the previous IPHDI (28). Despite health issues, the Madurese group has inferior stereotypes compared to other ethnic groups in East Java province (29).

Although the bivariate analysis shows there is a significant relationship between the education level and ethnicity, there is no difference between education levels in predicting pregnancy readiness. This finding shows that different education levels among married female adolescents from different ethnic groups do not contribute to give a significant impact on physical readiness for pregnancy. The results of this study are contradictory to some previous studies which found that education level was a positive predictor of many health outputs (30–32).

A previous systematic review found that better socioeconomic status, especially higher education, tends to have higher dietary scores, a greater consumption of fruits, vegetables, and dairy products, and lower consumption of sugar-sweetened beverages and energy-dense foods. While other lower education levels did not show a significant difference (33). The bivariate analysis shows that education level affected the choice of food consumed.

In a broader view, education levels of the female adolescents and young mothers are also closely related to nutritional status in adolescents. A study conducted in the Northwest Ethiopia discovers a close relationship between poor nutritional status in adolescents and poor education levels of their mothers. Mothers with low education level were 2.84 times more likely to have stunted or short children than mothers with higher education level (34). Similarly, another study in West Java, Indonesia foundmothers with lower education level were 1.19 times more likely to have short children compared to mothers with higher education level (35).

Previous studies in various countries inform that education level affected the anemia and nutritional status (36–38), including overweight status (39). A slight deviation was found in India where literacy, economic, and physical activity status were the most significant predictors that affected nutritional status. Specifically, differences in reading ability became the predictor of the nutritional status in adolescents, but education level did not (40).

Conclusions

It can be concluded that there were partial differences in pregnancy readiness between married female adolescents from different ethnicities in Probolinggo district, East Java, Indonesia. Madurese married female adolescents had a lower possibility being ready for pregnancy than Java ethnic group. Besides, other variables were not the predictors of pregnancy readiness among those married female adolescents.

Declarations
Ethics approval and consent to participate

This study has received ethical clearance from the Faculty of Medicine Gadjah Mada University, Yogyakarta, Indonesia (Number KE/FK/202/EC). In this study, an informed consent was used during data collection by considering the data collection procedures, voluntary participation, and confidentiality of respondents’ profile. The parents or guardians of the adolescents have given a written consent for the adolescents’ participation in this study. All respondents’ identities have been removed from the dataset.

Consent for publication
