ISOGEOMETRIC BOUNDARY ELEMENTS IN ELECTROMAGNETISM: RIGOROUS ANALYSIS, FAST METHODS, AND EXAMPLES

JÜRGEN DÖLZ*, STEFAN KURZ*, SEBASTIAN SCHÖPS*, AND FELIX WOLF*

Abstract. We present a new approach to three-dimensional electromagnetic scattering problems via fast isogeometric boundary element methods. Starting with an investigation of the theoretical setting around the electric field integral equation within the isogeometric framework, we show existence, uniqueness, and quasi-optimality of the isogeometric approach. For a fast and efficient computation, we then introduce and analyze an interpolation-based fast multipole method tailored to the isogeometric setting, which admits competitive algorithmic and complexity properties. This is followed by a series of numerical examples of industrial scope, together with a detailed presentation and interpretation of the results.

1. Introduction. As has been shown since their introduction by [30] in 2005, isogeometric methods offer a variety of advantages over triangulation-based approaches. Not only do they allow for an exact geometry representation via parametric mappings, but also improved spectral properties and higher accuracies per degree of freedom (DOF) have been shown in [16].

The interest for isogeometric boundary element methods is rooted in the need for volumetric mappings by classical isogeometric analysis (IGA). These are usually not provided by computer-aided design (CAD) frameworks since most CAD systems handle only boundary representations. Boundary element methods, which already exploited the possibility of exact geometry representations via parametric mappings before the introduction of IGA [27], avoid this problem by reducing the problem at hand to an integral equation operating exclusively on the boundary of the domain of interest. Moreover, since merely a boundary representation must be available, this makes boundary element methods exceptionally well suited for exterior problems, specifically scattering problems. The adaptation of this to the isogeometric framework has spawned a whole area of research, see, e.g., [1, 19, 20, 21, 28, 33, 43, 44] and the references therein.

Although the independence of volumetric mappings is one major strongpoint of isogeometric boundary element methods, there are hindrances to be aware of. First, they rely on the existence of fundamental solutions, thus not all PDEs are solvable by a boundary element approach. Second, due to the non-local formulation, the arising systems are dense, and thus boundary element methods rely on so-called fast methods to be used efficiently, see eg. [3, 23, 24, 25, 27, 28].

While solid implementations and analysis for acoustic scattering exist, cf., e.g., [20], the efficient solution of the more involved electromagnetic problems is still an open area of research, but of vast interest for the electromagnetic engineering community [7]. Implementations of (lowest-order) boundary element schemes for electromagnetic scatterings, mostly based on the electric field integral equation (EFIE), are widely accepted by industry, and classical implementations are well understood, cf. [37]. Implementations realizing the isogeometric approach as first presented by [15] exist

State of Research

Results of this Paper

Figure 1.1: A diagram showcasing the intention of this paper. Blue represents crucial algorithmic advances, and green the corresponding analysis. It gives the state of research (blocks) on the isogeometric formulation of the electric field integral equation (EFIE), as well as open questions, which have not yet fully been discussed in the literature (circled). We aim to discuss these within this paper and present a fast scheme which is verified by theory. Note that for classical approaches to the electric field integral equation most of these issues have been resolved already.

as well, cf. [42]. However, many open questions about the theory and behavior of this approach remain open, and the potential of fast methods is far from being fully exploited.

The contribution of this paper is threefold, cf. Figure 1.1. First, the existence and uniqueness of the discrete solutions from the isogeometric approach are unclear. Classical proofs for other discretizations rely on commuting interpolation operators, see [6, 10, 12], which have been obtained only recently for the isogeometric approach in the multi-patch setting [11]. Under the view of these developments, we establishing a discrete inf-sup-condition which yields existence and uniqueness for isogeometric discretizations of the electric field integral equation. Together with recent approximation results [11], this guarantees optimal convergence rates.

The second point this paper is concerned with is the need for an efficient fast method for this framework. The issue with common methods, see, e.g., [3, 23, 24, 25], is the fact that they were designed for lower order trial spaces and iterate over the degrees of freedom – rather than the elements – during numerical quadrature. Applying this approach to higher order spline spaces as done in [42] results in difficult bookkeeping
of the supports and expensive numerical quadrature, since redundant evaluations of geometry and fundamental solution are inevitable.

In this paper, we follow the approach of [19, 39], which allows for a fast method with element-wise quadrature and fully avoids redundant evaluations of geometry and fundamental solution. Our method exploits the isogeometric structure and yields a simplified implementation based on interpolation on the unit square. Moreover, the approach fits effortlessly into the $H^2$-matrix framework [8], which is a more efficient specialization of the frequently used $H$-matrix framework [26]. However, one should be aware that the approximation of the system by fast methods directly influences the quality of the solution. Thus, the induced error needs to be well understood and controlled. We provide a detailed analysis of the presented method which shows that it maintains the proven optimal convergence rates. To best of our knowledge, this makes the method in this paper the only fast method for isogeometric boundary elements for the electric field integral equation which is mathematically sound and computationally efficient.

This document is structured as follows. Section 2 reviews the basic notions required for an analysis of the electric field integral equation and its discretization within the isogeometric framework, which will be formulated in Section 3. This is followed by a discussion of existence, uniqueness, and quasi-optimality of the solution to the arising variational problem. Afterward, in Section 4, we introduce and analyze an interpolation-based fast multipole approach. Section 5 then introduces numerical experiments of different sizes, in which we investigate the behavior of our method, with both the surface current and the scattered field as a quantity of interest in mind. Finally, in Section 6, we conclude and reflect our results.

Throughout this paper, in order to avoid the repeated use of generic but unspecified constants, by $C \lesssim D$ we mean that $C$ can be bounded by a multiple of $D$, independently of parameters which $C$ and $D$ may depend on. In the usual sense, $C \gtrsim D$ is defined as $D \lesssim C$, and $C \simeq D$ as $C \lesssim D \lesssim C$.

2. Fundamental Concepts. We first introduce the required mathematical framework for a precise introduction of the scattering problem for which we follow the leads of [12]. Afterward, we will introduce the electric field integral equation and review some of its properties.

2.1. The Electromagnetic Scattering Problem. On the bounded domain $\Omega \subset \mathbb{R}^3$ and for $0 \leq s$, we denote by $H^s(\Omega)$ the usual Sobolev spaces [34], and by $H^s(\Omega)$ their vector valued counterparts. For $s = 0$ we utilize the convention $H(\Omega) = H^0(\Omega) = L^2(\Omega)$ and $H(\Omega) = H^0(\Omega) = L^2(\Omega)$. On unbounded domains $\Omega^c := \mathbb{R}^3 \setminus \overline{\Omega}$ we utilize the same notation together with the subscript “loc” in the form of $H^s_{\text{loc}}(\Omega^c)$ and $H^s_{\text{loc}}(\Omega^c)$ to denote that the required regularity conditions must only be fulfilled on all bounded subdomains of $\Omega^c$.

For compact manifolds $\Gamma$ we denote by $H^s(\Gamma)$ the usual construction of Sobolev spaces on manifolds via charts, and by $H^s(\Gamma)$ their vector valued counterparts. As common, we define the spaces $H^{-s}(\Gamma)$ and $H^{-s}(\Gamma)$ as the dual spaces of $H^s(\Gamma)$ and $H^s(\Gamma)$ w.r.t. $L^2(\Gamma)$ and $L^2(\Gamma)$ as pivot spaces.

Let $\mathcal{M}$ be one of the domains $\Omega$, $\Omega^c$, or the boundary $\Gamma$. For any differential operators $d$ defined on $\mathcal{M}$, we define the spaces $H^s(d,\mathcal{M})$ via the closure of $H^s(\mathcal{M})$ under the graph norm $\|d(\cdot)\|_{H^s(\mathcal{M})}$, equipping the spaces with the same. The definition of graph norms is generalised to vector-valued differential operators and spaces in complete analogy. The following trace operator for vector fields onto Lipschitz boundaries will be required to describe meaningful boundary data to the
electric wave equation.

**Definition 2.1 (Rotated Tangential Trace Operators, [12]).** For \( u \in C(\Omega^c; \mathbb{R}^3) \), with \( \Omega \) being a domain with Lipschitz boundary, we define the exterior rotated tangential trace operator as

\[
\gamma_i^+ (u)(x_0) := \lim_{x \to x_0 \atop x \in \Omega^c} u(x) \times n_{x_0}, \quad \text{for all } x_0 \in \Gamma,
\]

where \( n_{x_0} \) denotes the exterior normal vector of \( \Omega \) at \( x_0 \). We add the “+” to our notation to stress the fact that we consider the trace from the exterior domain only.

By density arguments, see also [12], this notation can be extended to be applicable to the spaces \( H^{s+1/2}_{\text{loc}}(\Omega^c) \) for \( 0 < s < 1 \) and \( H^s_{\text{loc}}(\text{curl}, \Omega^c) \). Thus, we define \( H^s_\times(\Gamma) := \gamma_i^+ (H^{s+1/2}_{\text{loc}}(\Omega^c)) \) for all \( 0 < s < 1 \) as well as

\[
H^{-1/2}_\times(\text{div}, \Gamma) := \gamma_i^+ (H^1_{\text{loc}}(\text{curl}, \Omega^c)).
\]

It is known that \( \gamma_i^+ : H^s_{\text{loc}}(\text{curl}, \Omega^c) \to H^{-1/2}_\times(\text{div}, \Gamma) \) is a bounded linear operator [12].

With respect to the pairing

\[
(\mu, \nu)_\times = \int_\Gamma (\mu \times n_\Gamma) \cdot \nu \, d\sigma_\Gamma
\]

we define the spaces \( H^s_\times(\Gamma) \) by duality to \( H^s_\times(\Gamma) \) for \( 0 < s < 1 \). Note, however, that the space \( H^{-1/2}_\times(\text{div}, \Gamma) \) cannot be defined via such a duality if \( \Gamma \) is non-smooth, cf. [12].

Given a perfectly conducting object \( \Omega \) with Lipschitz boundary \( \Gamma \) in a surrounding \( \Omega^c \), we are interested in the scattered field \( e_s \) of an electric incident wave \( e_i \) hitting the scatterer \( \Omega \). Assuming a time-harmonic problem, the scattered field \( e_s \) can then be described in the frequency domain by the **electric wave equation**

\[
\begin{align*}
\nabla \times e_s - \kappa^2 e_s &= 0 \quad \text{in } \Omega^c, \\
\gamma_i^+ e_s &= -\gamma_i^+ e_i \quad \text{on } \Gamma, \\
|\nabla e_s(x) \times x|^{-1} - i\omega\varepsilon_0 e_s(x)| &= O(|x|^{-2}), \quad |x| \to \infty.
\end{align*}
\]

The wavenumber \( \kappa = \omega\sqrt{\varepsilon_0\mu_0} \) is described in terms of the frequency \( \omega \), as well as the material parameters permittivity \( \varepsilon_0 > 0 \) and permeability \( \mu_0 > 0 \), which we assume to be constant. It is known that (2.1) is uniquely solvable for any sufficiently regular Dirichlet data and wavenumbers \( \kappa > 0 \), see [13]. Given an incident wave \( e_i \), the total electric field \( e \) in \( \Omega^c \) is then given by \( e = e_i + e_s \).

**2.2. The Electric Field Integral Equation.** Since (2.1) is an unbounded exterior problem in a homogeneous medium, it is convenient to use the following boundary integral representation.

**Lemma 2.2 (Representation Formula, [12]).** For any solution \( e_s \) of (2.1) there exists a density \( w \in H^{-1/2}_\times(\text{div}, \Gamma) \) such that \( e_s(x) = (\tilde{V}_s w)(x) \) for all \( x \in \Omega^c \), where

\[
(\tilde{V}_s w)(x) = \int_\Gamma G_\alpha(x-y) w(y) \, d\sigma_y + \frac{1}{\kappa^2} \text{grad}_x \int_\Gamma G_\alpha(x-y) \text{div}_\Gamma w(y) \, d\sigma_y.
\]
$G_\kappa(x - y)$ is herein given by the Helmholtz fundamental solution

$$G_\kappa(x - y) = \frac{e^{i\kappa\|x - y\|}}{4\pi\|x - y\|}. \tag{2.3}$$

Moreover, the electric single layer potential given in (2.2) is a continuous operator

$\tilde{\mathbf{V}}_\kappa: H_{\times}^{-1/2}(\text{div}_\Gamma, \Gamma) \to H_{\text{loc}}(\text{curl} \text{ curl}, \Omega^c)$, such that the image of $\tilde{\mathbf{V}}_\kappa$ is divergence free within $\Omega^c$.

We remark that the very same representation formula holds also for the electric wave equation in the bounded domain $\Omega$, which we shall not need here. However, for our following considerations it is important to keep in mind that the interior and the exterior problem are closely related to each other. More precisely, the following considerations for the exterior problem fail, if $\kappa$ is a resonant wavenumber of the interior problem, see [12] for a precise definition and discussion.

By the Lemma above we know that a density $\mathbf{w}$ with $\mathbf{e}_i = \tilde{\mathbf{V}}_\kappa \mathbf{w}$, exists. To obtain it, we apply the tangential trace on both sides of (2.2), which yields the electric field integral equation

$$-\gamma_+^i \mathbf{e}_i = (\gamma_+^i \tilde{\mathbf{V}}_\kappa)(\mathbf{w}) =: \mathbf{V}_\kappa \mathbf{w}. \tag{2.4}$$

The variational formulation for the electric field integral equation (2.4) is as follows.

**Continuous Problem.** Find $\mathbf{w} \in H_{\times}^{-1/2}(\text{div}_\Gamma, \Gamma)$ such that

$$\langle \mathbf{V}_\kappa \mathbf{w}, \xi \rangle = -\langle \gamma_+^i \mathbf{e}_i, \xi \rangle, \tag{2.5}$$

for all $\xi \in H_{\times}^{-1/2}(\text{div}_\Gamma, \Gamma)$.

As done in [9], one can utilize a generalized Gårding-inquality to show well posedness of this continuous problem for non resonant wavenumbers.

**Remark 2.3.** Other than in the case of indirect representation formulas for scalar problems, the density $\mathbf{w}$ for the electric field integral equation has a physical interpretation in terms of the surface current, cf. [31].

### 3. The Discrete Problem.

We will now discuss the technical details and analytic properties for the discretization of (2.5). Since much of the following analysis is based on the approximation results of [11], we will follow its notation closely. For a more in-depth introduction to spline theory we refer to [41], and to its application to variational isogeometric analysis to [5].

#### 3.1. Fundamental Notions.

We review the basic notions of isogeometric analysis, restricting ourselves to spaces constructed via locally quasi uniform $p$-open knot vectors as required by the theory presented in [5, 11].

**Definition 3.1 (B-Splines, [5]).** Fix $p$ and $k$ such that $0 \leq p < k$. A locally quasi uniform $p$-open knot vector is given by a set

$$\Xi = [\xi_0 = \cdots = \xi_p \leq \cdots \leq \xi_k = \cdots = \xi_{k+p}] \in [0,1]^{k+p+1}$$

with $\xi_0 = 0$ and $\xi_{k+p} = 1$ such that there exists a constant $\theta \geq 1$ such that for all $p \leq j < k$ one finds $\theta^{-1} \leq h_j \cdot h_{j+1}^{-1} \leq \theta$, where $h_j := \xi_{j+1} - \xi_j$ for all $\xi_j, \xi_{j+1} \in \Xi$. The
B-spline basis \( \{ b_j^p \}_{0 \leq j < k} \) is now defined by recursion as

\[
b_j^p(x) = \begin{cases} 
\chi(\xi_j, \xi_{j+1}) & \text{if } p = 0, \\
\frac{x-\xi_j}{\xi_{j+p+1}-\xi_j} b_{j+1}^{p-1}(x) + \frac{\xi_{j+p+1}-x}{\xi_{j+p+1}-\xi_{j+1}} b_{j+1}^{p-1}(x) & \text{else},
\end{cases}
\]

where \( \chi_M \) denotes the indicator function for a set \( M \). Moreover, we define the spline space \( S^p(\Xi) := \text{span}\{b_j^p\}_{j<k} \).

To obtain spline spaces in two spacial dimensions, define, for a tuple \( \Xi = (\Xi_1, \Xi_2) \) and polynomial degrees \( p = (p_1, p_2) \) the spaces \( S^p(\Xi) := S^{p_1}(\Xi_1) \otimes S^{p_2}(\Xi_2) \). Given knot vectors \( \Xi_1, \Xi_2 \) with knots \( \xi_{i_0} < \xi_{i_k+1} \) and \( \xi_{i_k}, \xi_{i_{k+1}} \in \Xi_k \) for both, \( k = 1, 2 \), sets of the form \( [\xi_{j_1}, \xi_{j_1+1}] \times [\xi_{j_2}, \xi_{j_2+1}] \), will be called elements. We reserve the letter \( h \) for the maximal diameter of all elements.

Let \( \square := [0, 1]^2 \) denote the unit square. As usual in the framework of isogeometric analysis, the geometry \( \Gamma = \bigcup_{j \leq N} \Gamma_j \) will be given as a family of mappings

\[
F_j : \square \to \Gamma_j \subset \mathbb{R}^3,
\]

which we will refer to as parametrization. These mappings will be given by NURBS mappings, i.e., by mappings with a representation

\[
F_j(x,y) := \sum_{0 \leq j_1 < k_1} \sum_{0 \leq j_2 < k_2} \frac{c_{j_1,j_2} b_{j_1}^{p_1}(x) b_{j_2}^{p_2}(y) w_{j_1,j_2}}{\sum_{i_1=0}^{k_1-1} \sum_{i_2=0}^{k_2-1} b_{i_1}^{p_1}(x) b_{i_2}^{p_2}(y) w_{i_1,i_2}},
\]

for control points \( c_{j_1,j_2} \in \mathbb{R}^3 \) and weights \( w_{i_1,i_2} > 0 \). For further concepts and algorithmic realization of the NURBS we refer to [38].

We assume the multipatch geometries \( \Gamma = \bigcup_{j \leq N} \Gamma_j \) to be piecewise smooth and orientable manifolds arising as boundaries of Lipschitz domains. Moreover, we assume any mapping of the parametrization to be non-singular and invertible. On any interface \( \Gamma_j \cap \Gamma_k \neq \emptyset \) we require the involved mappings to coincide, i.e., \( F_j(\cdot, 1) \equiv F_k(\cdot, 0) \) must be satisfied up to orientation of the reference domain.

We remark that, as long as the assumptions stated above are fulfilled, the description of the geometry is independent of the analysis that will follow, i.e., one could choose sufficiently regular mappings that are not representable via NURBS, for example, mappings containing trigonometric functions.

### 3.2. A Conforming Discretization.

Let \( F_j : \square \to \Gamma_j \) be a mapping of the parametrization of \( \Gamma \). Defining the surface measure \( \tau \) via

\[
\tau(x) := \| \partial_x F_j(x) \times \partial_y F_j(x) \|_{\mathbb{R}^3}, \quad x \in \square,
\]

the geometry transformations required for an analysis of isogeometric boundary element methods are of the form

\[
\begin{align*}
u_0(F_j)(f_0)(x) & := (f_0 \circ F_j)(x), & x \in \square, \\
u_1(F_j)(f_1)(x) & := (\tau \cdot (dF_j)^{-1})(f_1 \circ F_j)(x), & x \in \square, \\
u_2(F_j)(f_2)(x) & := (\tau \cdot (f_2 \circ F_j))(x), & x \in \square.
\end{align*}
\]
Throughout this paper, we will denote by \( (t_0(F_j))^{-1}(f_0)(x) = (f_0 \circ F_j^{-1})(x), \) \( x \in \Gamma_j, \)
\( (t_1(F_j))^{-1}(f_1)(x) = \left( \tau^{-1} \cdot (dF_j)^T (f_1 \circ F_j^{-1}) \right)(x), \) \( x \in \Gamma_j, \)
\( (t_2(F_j))^{-1}(f_2)(x) = \left( \tau^{-1} \cdot (f_2 \circ F_j^{-1}) \right)(x), \) \( x \in \Gamma_j, \)
where the computation of the inverse \( F_j^{-1} \) is not required, since all discrete entities are known and constructed w.r.t. the reference coordinates.

An important property of these geometry transformations is that the following diagram

\[
\begin{array}{cccc}
H^1(\Gamma_j) & \text{curl} & H(\text{div}\Gamma, \Gamma_j) & \text{div} & L^2(\Gamma_j) \\
\downarrow t_0 & & \downarrow t_1 & & \downarrow t_2 \\
H^1(\square) & \text{curl}_\Gamma & H(\text{div}\square) & \text{div}_\Gamma & L^2(\square)
\end{array}
\]

commutes [11, 36]. Thus, a conforming spline basis of \( H^1(\square) \) yields automatically conforming finite dimensional discretization of the entire diagram. More precisely, given polynomial degrees \( p_1, p_2 > 0 \), the mapping properties of the differential operators yield the conforming spline spaces

\[
\begin{align*}
S^0_{p,\Xi}(\square) & := S^{p_1, p_2}(\Xi_1, \Xi_2), & \subset H^1(\square), \\
S^1_{p,\Xi}(\square) & := S^{p_1, p_2-1}(\Xi_1, \Xi_2^1) \times S^{p_1-1, p_2}(\Xi_1^1, \Xi_2), & \subset H^0(\text{div}, \square), \\
S^2_{p,\Xi}(\square) & := S^{p_1-1, p_2-1}(\Xi_1^1, \Xi_2^1), & \subset L^2(\square),
\end{align*}
\]
together with their mapped counterparts on the surface.

For the multipatch boundary \( \Gamma = \bigcup_{j \leq N} \Gamma_j \) let \( \Xi := (\Xi_j)_{j \leq N} \) be an \( N \)-tuple of knot vectors as in Definition 3.1. Let \( p = (p_j)_{j \leq N} \) an \( N \)-tuple of pairs of integers \( p_j = (p_{1, j}, p_{2, j}) \), corresponding to polynomial degrees for each patch \( \Gamma_j \). Then we define the spline complex on the boundary \( \Gamma \) via

\[
\begin{align*}
S^0_{p,\Xi}(\Gamma) & := \left\{ f \in H^{1/2}(\Gamma) : t_0(F_j)(f|_{\Gamma_j}) \in S^0_{p,\Xi}(\square) \text{ for all } j \leq N \right\}, \\
S^1_{p,\Xi}(\Gamma) & := \left\{ f \in H^{-1/2}(\text{div}\Gamma, \Gamma) : t_1(F_j)(f|_{\Gamma_j}) \in S^1_{p,\Xi}(\square) \text{ for all } j \leq N \right\}, \\
S^2_{p,\Xi}(\Gamma) & := \left\{ f \in H^{-1/2}(\Gamma) : t_2(F_j)(f|_{\Gamma_j}) \in S^2_{p,\Xi}(\square) \text{ for all } j \leq N \right\}.
\end{align*}
\]

Throughout this paper, we will denote by \( p \) the minimal polynomial degree used for the construction of \( S^0_{p,\Xi}(\Gamma) \).

Remark 3.2. In the spirit of the isogeometric paradigm, degrees and knot vectors of the discrete B-spline spaces can be chosen to match the properties of the geometry discretization [30]. Note, however, that there is no theoretical requirement for \( p \) and \( \Xi \) to match the discretization of the geometry if we assume sufficient regularity of the parametrization. This fact will be used later on to benchmark different orders of discretization on the same geometry.
By definition of the spline spaces above, the sequence
\( S^0_{p, \Xi}(\Gamma) \xrightarrow{\text{curl}_\Gamma} S^1_{p, \Xi}(\Gamma) \xrightarrow{\text{div}_\Gamma} S^2_{p, \Xi}(\Gamma) \)
is a conforming multipatch discretization of the two-dimensional sequence
\( H^{1/2}(\Gamma) \xrightarrow{\text{curl}_\Gamma} H^{-1/2}_\times(\text{div}_\Gamma, \Gamma) \xrightarrow{\text{div}_\Gamma} H^{-1/2}(\Gamma). \)

We refer to [11] for an in-depth discussion on how these spline spaces on the boundary are connected with the B-spline discretization of the three-dimensional de Rham sequence.

Replacing \( H^{-1/2}_\times(\text{div}_\Gamma, \Gamma) \) by \( S^1_{p, \Xi}(\Gamma) \subset H^{-1/2}_\times(\text{div}_\Gamma, \Gamma) \) yields the discrete variational problem to (2.5), given as follows.

**Discrete Propblem.** Find \( w_h \in S^1_{p, \Xi}(\Gamma) \) such that
\[
\langle \mathcal{V}_\kappa w_h, \mu_h \rangle_\Gamma = -\langle \gamma_i^+ e_i, \mu_h \rangle_\Gamma,
\]
for all \( \mu_h \in S^1_{p, \Xi}(\Gamma) \).

Given a basis \( \{ \varphi_i \}_{i=1}^N \) of \( S^1_{p, \Xi}(\Gamma) \), this yields the linear system
\[
\mathcal{V}_\kappa w_h = -f_h,
\]
where the right-hand side \( f_h \) is given by \( [f_h]_j = \langle \gamma_i^+ e_i, \varphi_j \rangle_\times \) and the system matrix \( \mathcal{V}_\kappa \) by
\[
[\mathcal{V}_\kappa, w_h = -f_h,
\]
(3.6)
\[
\mathcal{V}_\kappa, w_h = -f_h,
\]
where the right-hand side \( f_h \) is given by \( [f_h]_j = \langle \gamma_i^+ e_i, \varphi_j \rangle_\times \) and the system matrix \( \mathcal{V}_\kappa \) by
\[
\mathcal{V}_\kappa, w_h = -f_h,
\]
(3.7)
\[
\mathcal{V}_\kappa, w_h = -f_h,
\]
see also [12]. We remark that the system matrix is symmetric, but not Hermitian.

**3.3. Approximation Properties and Discrete Inf-Sup Condition.** The conforming spline spaces introduced in the previous section provide approximation results of optimal order in \( H^{-1/2}_\times(\text{div}_\Gamma, \Gamma) \), w.r.t. patchwise regularity. Therefore, setting \( s \geq 0 \), we define the patchwise norms
\[
\| f \|_{H^s(\Gamma)} := \sum_{j \leq N} \| f \|_{H^s(\Gamma_j)}, \quad \| g \|_{H^s(\text{div}_\Gamma, \Gamma)} := \sum_{j \leq N} \| g \|_{H^s(\text{div}_\Gamma, \Gamma_j)},
\]
for all functions \( f \in L^2(\Gamma) \) and \( g \in H^{-1/2}_\times(\text{div}_\Gamma, \Gamma) \) for which these expression is well defined. The corresponding spaces of higher patchwise regularity are defined canonically as subspaces of \( L^2(\Gamma) \) and \( H(\text{div}_\Gamma, \Gamma) \) with finite norm, see [11].

**Theorem 3.3** (Approximation Properties of \( S^1_{p, \Xi}(\Gamma) \), [11]). Let \( f \in H^s(\text{div}_\Gamma, \Gamma) \), \( 0 \leq s \leq p \) and denote by \( f_h \) the \( H^{-1/2}_\times(\text{div}_\Gamma, \Gamma) \)-orthogonal projection of \( f \) onto \( S^1_{p, \Xi}(\Gamma) \). Then one finds
\[
\| f - f_h \|_{H^{-1/2}_\times(\text{div}_\Gamma, \Gamma)} \lesssim h_1^{1/2+s} \| f \|_{H^s(\text{div}_\Gamma, \Gamma)}.
\]
According to the classical theory of the electric field integral equation the following holds.

**Lemma 3.4 (Criteria for a Stable Discretization, [9, Prop. 4.1]).** Under the assumptions that

1. there exists a continuous splitting $H^{-1/2}_{×}(\text{div}_{\Gamma}, \Gamma) = \mathbf{W} \oplus \mathbf{V}$ such that the bilinear form induced by the variational formulation (2.5) is stable and coercive on $\mathbf{V} \times \mathbf{V}$ and $\mathbf{W} \times \mathbf{W}$, and compact on $\mathbf{V} \times \mathbf{W}$ and $\mathbf{W} \times \mathbf{V}$,
2. $S_{p,\Xi}(\Gamma)$ can be decomposed into a sum $S_{p,\Xi}(\Gamma) := \mathbf{W}_h \oplus \mathbf{V}_h$ of closed subspaces of $H^{-1/2}_{×}(\text{div}_{\Gamma}, \Gamma)$,
3. $\mathbf{W}_h$ and $\mathbf{V}_h$ are stable under complex conjugation, and
4. it holds that $\mathbf{W}_h \subseteq \mathbf{W}$ as well as

$$
\sup_{\mathbf{v}_h \in \mathbf{V}_h} \inf_{\mathbf{v} \in \mathbf{V}} \frac{\|\mathbf{v} - \mathbf{v}_h\|_{H^{-1/2}_{×}(\text{div}_{\Gamma}, \Gamma)}}{\|\mathbf{v}_h\|_{H^{-1/2}_{×}(\text{div}_{\Gamma}, \Gamma)}} \xrightarrow{\mathbf{h} \to 0} 0,
$$

the discrete problem (3.5) enjoys inf-sup-stability.

The continuous splitting of $H^{-1/2}_{×}(\text{div}_{\Gamma}, \Gamma)$ has been discussed in the literature, see, e.g., [12], and is required for proving the inf-sup-stability of (2.5). Analogously to the derivation of the continuous splitting, we can define a suitable discrete splitting.

One of the most concise (although not self-contained) constructions of said splitting consists of divergence free functions [6, Eq. 3.5].

Indeed, one can show the continuous inf-sup-condition via the splitting $\mathbf{V} := (R)(H^{-1/2}_{×}(\text{div}_{\Gamma}, \Gamma))$ and $\mathbf{W} := (\text{Id} - R)(H^{-1/2}_{×}(\text{div}_{\Gamma}, \Gamma))$, where, by Lemma 3.5, $\mathbf{W}$ consists of divergence free functions [6, Eq. 3.5].

The construction of a corresponding discrete splitting relies on the multipatch interpolation operators introduced in [11], given by

$$
\Pi_{1}^{0} : \quad H^{1/2}(\Gamma) \ni \mathcal{D}(\Pi_{1}^{0}) \to S_{p,\Xi}^{0}(\Gamma),
$$

$$
\Pi_{1}^{1} : \quad H^{-1/2}_{×}(\text{div}_{\Gamma}, \Gamma) \ni \mathcal{D}(\Pi_{1}^{1}) \to S_{p,\Xi}^{1}(\Gamma),
$$

$$
\Pi_{1}^{2} : \quad H^{-1/2}(\Gamma) \ni \mathcal{D}(\Pi_{1}^{2}) \to S_{p,\Xi}^{2}(\Gamma),
$$

with domains $\mathcal{D}(\cdot)$. Note that these projections commute with the surface differential operators $\text{curl}_{\Gamma}$ and $\text{div}_{\Gamma}$, i.e., one finds

$$
(\text{curl}_{\Gamma} \circ \Pi_{1}^{0})(f) = (\Pi_{1}^{0} \circ \text{curl}_{\Gamma})(f),
$$

$$
(\text{div}_{\Gamma} \circ \Pi_{1}^{1})(f) = (\Pi_{1}^{2} \circ \text{div}_{\Gamma})(f).
$$

(3.8)
Among other estimates about these interpolation operators, \cite{11} provides the following.

**Lemma 3.6.** Let $f \in \tilde{H}^s(\Gamma)$ for $1 \leq s \leq p$. Then it holds that

$$
\|f - \tilde{\Pi}_1 f\|_{L^2(\Gamma)} \lesssim h^s \|f\|_{\tilde{H}^s(\Gamma)}.
$$

By the first assertion of Lemma 3.5 and the construction and properties of the quasi-interpolation operators constructed in \cite{11}, the definition of the discrete splitting via

$$
V_h := (\tilde{\Pi}_1 \circ R)(S_{p,\Xi}(\Gamma)), \quad W_h := (\text{Id} - \tilde{\Pi}_1 \circ R)(S_{p,\Xi}(\Gamma)),
$$

would be a suitable candidate to fulfill the assumptions of Lemma 3.4. That this splitting is well defined and indeed satisfies all necessary conditions will be discussed in the proof of the upcoming Proposition.

For its proof, we need some extra assumptions to provide stability of the discrete problem. For this purpose, it is most convenient to require

\[ c(\Gamma) \geq 1 \quad (3.9) \]

in Lemma 3.5. This secures that we can choose $\epsilon = 1$, and thus apply the approximation result of Lemma 3.6 to the image of $R$. This is a requirement on the geometry, which is given in many cases, but not fulfilled in some pathological cases, cf. \cite[Thm. 8]{10}.

Indeed, if one were able to provide a result

\[ \|f - \tilde{\Pi}_1 f\|_{L^2(\Gamma)} \lesssim h^\epsilon \|f\|_{H^s(\Gamma)}, \quad \forall f \in RV, \quad (3.10) \]

for a range of $\epsilon < 1$ and (possibly modified) commuting interpolation operators, one could include the exceptions to (3.9) in the proof. Such a result has been provided for classical electromagnetic boundary element methods for $\epsilon = 1/2$, see, e.g., \cite{6}. However, an investigation of (3.10) for the spline spaces is beyond the scope of this document.

We are now ready to provide a statement about the inf-sup-stability of the discretized EFIE.

**Proposition 3.7.** Assume (3.9) or (3.10). Then the discrete problem (3.5) enjoys inf-sup-stability.

**Proof.** We write

$$
\begin{align*}
\sup_{v_h \in V_h} \inf_{v \in V} \frac{\|v - v_h\|_{H^{-1/2}(\text{div}, \Gamma)}}{\|v_h\|_{H^{1/2}(\text{div}, \Gamma)}} &\lesssim \sup_{v_h \in V_h} \frac{\|Rv_h - v_h\|_{H^{-1/2}(\text{div}, \Gamma)}}{\|v_h\|_{H^{-1/2}(\text{div}, \Gamma)}} \\
&= \sup_{v_h \in V_h} \frac{\|\quad\|}{\|v_h\|_{H^{-1/2}(\text{div}, \Gamma)}} \rightarrow 0.
\end{align*}
$$

Note that the last equality holds because one can show that $\tilde{\Pi}_1 \circ R$ is a projection, as done in \cite[Sec. 6]{6}. Thus, it holds that

$$
(\tilde{\Pi}_1 \circ R)(V_h) = V_h := (\tilde{\Pi}_1 \circ R)(S_{p,\Xi}(\Gamma)).
$$

To show convergence to 0, one merely needs apply (3.9), or (3.10) in conjunction with the approximation estimates of the interpolation operators reviewed in Lemma 3.6, together with the continuity of $R$ as in Lemma 3.5. \qed
Following classical Babuška-Brezzi theory [2, 47], we can finally combine Proposition 3.7 and Theorem 3.3 and arrive at the main result of this section.

**Theorem 3.8** (Discretization Error). Let the assumptions of the previous Proposition hold. Then the solution to (3.5) exists and is unique.

Moreover, assuming \( w \in \tilde{H}^s(\text{div}, \Gamma) \) for some \( 0 < s \leq p \), for the solutions \( w \in H^{-1/2}_x(\text{div}, \Gamma) \) and \( w_h \in S^1_{p, \Xi}(\Gamma) \) of (2.5) and (3.5) we find that

\[
\| w - w_h \|_{H^{-1/2}_x(\text{div}, \Gamma)} \lesssim h^{s+1/2} \| w \|_{\tilde{H}^s(\text{div}, \Gamma)}.
\]

As a corollary, we can predict the expected convergence rates of the scattered electric field. Similar to scalar-valued problems, the convergence rate of the field doubles.

**Corollary 3.9.** Let \( x \in \Omega^c \) fixed. Let \( w \) be the solution to (2.5) and \( w_h \) the solution to the numerical problem (3.5). Then, for \( e_s = \tilde{\mathcal{V}}_s w \) and \( e_{s, h} = \mathcal{V}_s w_h \), it holds

\[
\| e_s(x) - e_{s, h}(x) \|_{L^2} \leq C(x) h^{2p+1} \| w \|_{\tilde{H}^p(\text{div}, \Gamma)},
\]

if \( w \) and the solution of a suitable adjoint problem are sufficiently smooth.

*Proof.* One readily verifies that \( (\tilde{\mathcal{V}}_s \cdot)(x) \) is a linear and continuous functional on \( H^{-1/2}_x(\text{div}, \Gamma) \) for given \( x \). Let then \( \varphi(x) \) be the solution of the adjoint problem of finding \( \varphi(x) \in H^{-1/2}_x(\text{div}, \Gamma) \) such that

\[
\langle \mathcal{V}_s \xi, \varphi(x) \rangle = (\tilde{\mathcal{V}}_s \xi)(x)
\]

holds for all \( \xi \in H^{-1/2}_x(\text{div}, \Gamma) \). Let \( \varphi_h(x) \) denote its discrete analogon. The assertion now follows by applying a standard argument, see also [40, Theorem 4.2.14], to each component of the scattered field to obtain

\[
\| e_s(x) - e_{s, h}(x) \|_{L^2} \lesssim \| w - w_h \|_{H^{-1/2}_x(\text{div}, \Gamma)} \| \varphi(x) - \varphi_h(x) \|_{H^{-1/2}_x(\text{div}, \Gamma)}.
\]

The previous theorem yields the assertion with \( C(x) = C \| \varphi(x) \|_{\tilde{H}^p(\text{div}, \Gamma)} \), if the solutions to (2.5) and (3.11) are smooth enough. \( \square \)

**Remark 3.10.** The proof applies to any linear and continuous output functional of \( w \). Thus, similar error estimates hold also for other quantities of interest, for example for path integrals of the electric field, i.e., voltages, which are often considered in electrical engineering, cf. [31].

**4. Implementation Detail.** This section is concerned with the efficient implementation of the electric field integral equation with conforming B-spline spaces in the isogeometric framework (3.6). The assembly of the system matrices will be discussed in the following subsection. Since, in general, the matrices will be densely populated, Section 4.2 discusses a fast compression method based on interpolation of the kernel function as introduced in [19, 20]. A particular feature of this approach is that its simple implementation integrates effortlessly into the \( H^2 \)-matrix framework [8], which is a more efficient variant of the commonly used \( H \)-matrix framework [26]. Section 4.3 is then concerned with the error analysis of the method.

Before we start, we briefly comment on the adaptive cross approximation, which has been used in [42]. Being a simple and purely algebraic algorithm, it is very popular
in the engineering community [32]. However, due to the overlapping supports of higher-order B-spline discretizations, it will inevitably lead to redundant kernel and geometry evaluations, and will thus become increasingly inefficient for higher order. In contrast, the scheme we are going to present in this section avoids such redundant computations by construction.

4.1. Assembly of the System Matrix. We assume that the B-spline space $S_p^1(\Gamma)$ is, on each patch $\Gamma_j$, generated by the tuple $\Xi_{m,j} = (\Xi_m, \Xi_m)$, where $\Xi_m$ is an equidistant knot vector with $2^m$, $m \geq 0$, elements. This corresponds to $m$ steps of uniform refinement in terms of the reference domain and generates a nested sequence of meshes. Then, for each level of refinement $m$, the mesh consists of $4^m$ elements per patch. The key point of this refinement strategy is that it induces a quadtree structure on the geometry, cf. Figure 4.1, which we will use for our compression scheme. Each element $\Gamma_{i,j,k}$ within the nested sequence of meshes will be referred to by a tuple $(i,j,k) =: \lambda$, where $i$ denotes the corresponding parametric mapping, $j$ showcases the level of refinement of the element and $k$ denotes the index of the element in hierarchically order. For notational purposes, we will define $|\lambda| = j$ and also introduce the diffeomorphisms $F_\lambda: \Box \to \Gamma_\lambda$ which can easily be defined by combining $F_i$ with a suitable affine transformation. For the efficient compression, each instance of $\Gamma_\lambda$ is also considered as a cluster, in the sense that $\Gamma_\lambda$ will be considered as the set of tree leaves appended to the subtree with root $\Gamma_\lambda$. Naïvely said, $\Gamma_\lambda$ can be visualised as “a square region on the geometry”. The hierarchically ordered collection of all $\Gamma_\lambda$ will be called cluster tree and denoted by $\mathcal{T}$.

For each pair of clusters in $\mathcal{T}$, the fundamental solution $G_\kappa$ from (2.3) can be localized to a localized kernel function

\begin{equation}
(4.1) \quad G_{\kappa, \lambda, \lambda'}: \Box \times \Box \to \mathbb{C}, \quad G_{\kappa, \lambda, \lambda'}(s,t) = G_\kappa(F_\lambda(s) - F_\lambda'(t))
\end{equation}

which reparametrizes the fundamental solution to $\Box \times \Box$. This reduces the dimension
(in terms of input variables) of the fundamental solution artificially.

On each element \( \Gamma_k \), ansatz functions \( \varphi_\lambda \) can be defined by lifting suitable shape functions \( \hat{\varphi} \) on \( \Box \) to the surface by \( \varphi_\lambda := \hat{\varphi} \circ \mathbf{F}_\lambda^{-1} \). To define suitable shape functions of polynomial degree \( p \) on \( \Box \), we introduce the knot vector \( \Xi^* \), which is generated from \( \Xi \) by increasing the multiplicity of each knot to \( p + 1 \). We then define the spaces \( S^*_{p,m}(\Box) \), to be the discontinuous spaces generated by \( \mathbf{p} = (p,p) \) and \( \Xi_m = (\Xi, \Xi^*) \). Then, for the particular case \( m = 0 \), \( S^*_{p,0}(\Box) \) contains all tensorised Bernstein polynomials of degree \( p \) on \( \Box \). Later, we will also require \( S^*_{p,m}(\Box), m > 0 \), which is generated by tensorised Bernstein polynomials of degree \( p \) on every element on the unit square. The span of all ansatz functions \( \varphi_\lambda \) with \( |\lambda| = m \) then yields a global discrete discontinuous function space \( S^*_{p,m}(\Gamma) \) of dimension \( k := 2^{2m} N(p+1)^2 \).

Since B-splines are piecewise polynomials, it clearly holds that

\[
S^*_{p,m}(\Box) \subset S^*_{p,m}(\Gamma) := S^*_{p,m}(\Box) \times S^*_{p,m}(\Gamma),
\]

with \( \mathbf{p} = (p,p) \) and \( \Xi_m = (\Xi, \Xi^*) \). We can therefore represent each basis function of \( S^*_{p,m}(\Gamma) \) by a linear combination of basis functions of \( S^*_{p,m}(\Box) \). This yields a transformation matrix \( \mathbf{T} \), which transforms the coefficient vector of a function in \( S^*_{p,m}(\Box) \) to the coefficient vector of the corresponding function in \( S^*_{p,m}(\Gamma) \). Then, instead of assembling the system of linear equations (3.6) with respect to \( S^*_{p,m}(\Box) \), one may assemble it with respect to \( S^*_{p,m}(\Gamma) \) to obtain a system matrix \( \mathbf{V}^*_{\kappa,h} \) and a vector \( \mathbf{f}^*_{\kappa,h} \). A linear system of equations equivalent to (3.6) is then given by

\[
T^\dagger \mathbf{V}^*_{\kappa,h} \mathbf{T} \mathbf{w} = -T^\dagger \mathbf{f}^*_{\kappa,h}.
\]

Since the dimension of \( S^*_{p,m}(\Gamma) \) is larger than the dimension of \( S^*_{p,m}(\Box) \), the matrix \( \mathbf{V}^*_{\kappa,h} \) is larger than the matrix \( \mathbf{V}^*_{\kappa,h} \). However, it has been shown in [39] for the case of classical higher order Raviart-Thomas elements that the superspace approach can achieve better compression rates and, thus, better computation times. In this particular case, the non-zero elements in \( \mathbf{T} \) were either 1 or -1. In [19, 20], the superspace approach has been applied to represent higher order B-spline spaces for Laplace and Helmholtz problems, where the elements of \( \mathbf{T} \) were the coefficients of a suitable basis transformation. Thus, the superspace approach in (4.2) can be implemented as a mixture of the two: Whereas, on each patch \( \Gamma_j \), one can use the approach of [20] to find a suitable transformation matrix between \( S^*_{p,m}(\Gamma_j) \times S^*_{p,m}(\Gamma_j) \) and \( S^*_{p,m}(\Gamma_j) \), one can use the approach of [39] to enforce continuity across patch boundaries. The transformation matrix \( \mathbf{T} \) can then be seen as the product of two sparse matrices.

Remark 4.1. From an implementation point of view, the transformation matrix between \( S^*_{p,m}(\Gamma_j) \times S^*_{p,m}(\Gamma_j) \) and \( S^*_{p,m}(\Gamma_j) \) can easily be constructed in a black-box fashion by exploiting the tensor product structure of the two spaces and spline-interpolation in one dimension.

The highly local support of the ansatz functions in \( S^*_{p,m}(\Gamma) \) will allow us to employ a version of the fast multipole method for the matrix compression which perfectly fits the framework of isogeometric analysis. Of course, one may also use any other compression method to approximate \( \mathbf{V}^*_{\kappa,h} \), but we will see that our version of the fast multipole method in combination with the structure of the isogeometric mappings directly fits into the efficient \( H^2 \)-matrix framework. Other compression methods tailored to isogeometric mappings, but in the lowest-order context and in the less efficient \( H \)-matrix framework, have been compared in [28].
Before we introduce the compression scheme, we first have to pull the matrix representation (3.7) back to the reference domain. According to [37], for two basis functions \( \varphi_i \) and \( \varphi_j \) of \( S_{p,m}^*(\Gamma) \) supported on \( \Gamma_{\lambda(i)} \) and \( \Gamma_{\lambda(j)} \), the first integral is given by

\[
\int_\Gamma \int_\Gamma G_k(\mathbf{x} - \mathbf{y}) \varphi_i(\mathbf{x}) \cdot \varphi_j(\mathbf{y}) \, d\sigma_y \, d\sigma_x
\]

and the second by

\[
\int_\Gamma \int_\Gamma G_k(\mathbf{x} - \mathbf{y}) \text{div}_\Gamma \varphi_j(\mathbf{x}) \text{div}_\Gamma \varphi_i(\mathbf{y}) \, d\sigma_y \, d\sigma_x
\]

Assuming that a finite dimensional basis of \( S_{p,m}^*(\Gamma) \) is given in terms of scalar functions, i.e.,

\[
\left\{ \begin{bmatrix} \varphi_i \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ \varphi_j \end{bmatrix} : \varphi_i, \varphi_j \text{ basis functions of } S_{p,m}^*(\Gamma) \right\},
\]

the matrix \( V_{p,m}^* \) can be further decomposed into

\[
V_{\kappa,h}^* = \begin{bmatrix}
V_{\kappa,h}^{(1,1)} & V_{\kappa,h}^{(1,2)} \\
V_{\kappa,h}^{(2,1)} & V_{\kappa,h}^{(2,2)}
\end{bmatrix},
\]

with

\[
\begin{bmatrix}
V_{\kappa,h}^{(\alpha,\beta)}
\end{bmatrix}_{i,j} = \int_\square \int_\square G_{\kappa,\lambda(i),\lambda(j)}(\mathbf{s},\mathbf{t}) \left( \left( \partial_\alpha F_{\lambda(i)}(\mathbf{s}), \partial_\beta F_{\lambda(j)}(\mathbf{t}) \right) \hat{\varphi}_j(\mathbf{t}) \hat{\varphi}_i(\mathbf{t}) 
\right) 
\]

for \( \alpha, \beta = 1, 2 \). Here, we denote by \( \hat{\varphi}_i \) the pullback of the basis function \( \varphi_i \) to the reference domain, i.e.,

\[
\hat{\varphi}_i = \varphi_i \circ F_{\lambda(i)}.
\]

This means that \( \hat{\varphi}_i \) is effectively an element of \( S_{p,0}^*(\square) \), i.e., it is the tensor product of Bernstein polynomials.

Remark 4.2. To obtain efficiency in an actual implementation, one may choose to simultaneously assemble the \( V_{\kappa,h}^{(\alpha,\beta)} \) and exploit the symmetry \( V_{\kappa,h}^{(1,1)} = (V_{\kappa,h}^{(1,2)})^\top \) and the symmetry of \( V_{\kappa,h}^{(1,1)} \) and \( V_{\kappa,h}^{(2,2)} \). Employing an element-wise integration scheme avoids redundant evaluations of kernel function and geometry. This can be maintained in the following compression scheme.

4.2. Compression of the System Matrix. Due to the non-locality of the fundamental solution \( G_k \), the system matrix \( V_{\kappa,h} \) given by (3.7) is densely populated. Its storage and assembly cost are thus prohibitively expensive for higher-dimensional ansatz and test spaces, and an efficient numerical implementation with compression technique is needed. We follow the approach of [19, 20] to compress the matrices \( V_{\kappa,h}^{(\alpha,\beta)}, \alpha, \beta = 1, 2 \), in terms of the fast multipole method, which yields a representation
Figure 4.2: Illustration of the $H^2$-matrix partitioning. All but the very smallest blocks are contained in the farfield and will be compressed by the fast multipole method.

of these matrices in terms of $H^2$-matrices, see also [8]. However, the approach is only applicable to matrices of the kind

$$[A]_{i,j} = \int_{\Gamma} \int_{\Gamma} G_{\kappa}(x-y) \varphi_j(x) \varphi_i(y) \, d\sigma_y \, d\sigma_x$$

$$= \int_{\square} \int_{\square} G_{\kappa,\lambda\lambda\lambda}(s,t) \hat{\varphi}_j(s) \hat{\varphi}_i(t) \, dt \, ds,$$

which does not readily fit the format of the matrices from (4.5) due to the derivatives of the geometry mappings and basis functions. In the following, we will, therefore, adapt the construction to the setting of the electric single layer operator.

For constructing the $H^2$-matrix representation, consider the level-wise Cartesian product $T \boxtimes T := \{ \Gamma_\lambda \times \Gamma_\lambda' : \Gamma_\lambda, \Gamma_\lambda' \in T, |\lambda| = |\lambda'| \}$ of the cluster tree $T$. Compressible matrix blocks are then identified by the following admissibility condition.

**Definition 4.3.** The clusters $\Gamma_\lambda$ and $\Gamma_\lambda'$ with $|\lambda| = |\lambda'|$ are called admissible if

$$(4.6) \quad \max \{ \text{diam}(\Gamma_\lambda), \text{diam}(\Gamma_\lambda') \} \leq \eta \text{dist}(\Gamma_\lambda, \Gamma_\lambda')$$

holds for a fixed $\eta \in (0,1)$. The largest collection of admissible blocks $\Gamma_\lambda \times \Gamma_\lambda' \in T \boxtimes T$ such that $\Gamma_{\text{dad}(\lambda)} \times \Gamma_{\text{dad}(\lambda')}$ is not admissible forms the far-field $F \subset T \boxtimes T$ of the operator. The remaining non-admissible blocks correspond to the near-field $N \subset T \boxtimes T$ of the operator.

The far-field conforms with the compressible matrix blocks, whereas the near-field is treated by the classical boundary element method, see Figure 4.2 for an illustration. The block-cluster tree $B := F \cup N$ can be constructed by Algorithm 4.1. We remark that for all block-clusters $\Gamma_\lambda \times \Gamma_\lambda' \in B$, it holds $|\lambda| = |\lambda'|$ and refer to [19, 28] for an in-depth discussion about the special properties of the block-cluster tree in the isogeometric setting.

For a given polynomial degree $q \in \mathbb{N}$, let $\{x_0, x_1, \ldots, x_q\} \subset [0,1]$ denote $q+1$ interpolation points. Furthermore, let $L_m(s)$ for $m = 0, \ldots, q$ be the Lagrangian basis polynomials with respect to these interpolation points. By a tensor product construction, one obtains the interpolation points $x_m := (x_{m_1}, x_{m_2})$ and the corresponding
We remark that the approach presented here interpolates the localized kernel (4.1) via Algorithm 4.1

$$\text{Algorithm 4.1 Construction of the block-cluster tree } \mathcal{B}$$

```
procedure BUILD_BLOCK_CLUSTER_TREE (cluster $\Gamma_\lambda, \Gamma_{\lambda'}$)
  if $(\Gamma_\lambda, \Gamma_{\lambda'})$ is admissible then
    sons$(\Gamma_\lambda \times \Gamma_{\lambda'}) := \emptyset$
  else
    sons$(\Gamma_\lambda \times \Gamma_{\lambda'}) := \{ \Gamma_\mu \times \Gamma_{\mu'} : \mu \in \text{sons}(\lambda), \mu' \in \text{sons}(\lambda') \}$
    for $\mu \in \text{sons}(\lambda), \mu' \in \text{sons}(\lambda')$ do
      BUILD_BLOCK_CLUSTER_TREE($\Gamma_\mu, \Gamma_{\mu'}$)
    end for
  end if
end procedure
```

Including the geometry information into the kernel evaluation yields

$$G_{\kappa, \lambda, \lambda'}(s, t) \approx \sum_{\|m\|_{\infty} \leq q, \|m'\|_{\infty} \leq q} G_{\kappa, \lambda, \lambda'}(x_m, x_{m'}) L_m(s) L_{m'}(t) =: \tilde{G}^{(q)}_{\kappa, \lambda, \lambda'}(s, t).$$

We remark that the approach presented here interpolates the localized kernel (4.1) via polynomials on the reference domain $\Box$ of the isogeometric mappings rather than the original kernel in space, as first introduced in [22, 25]. We will see that this will lead to a complexity of $q^2$ in terms of the interpolation degree of the compression, rather than $q^3$.

Including the geometry information into the kernel evaluation yields

$$V^{(\alpha, \beta)}_{\kappa, h} |_{\lambda, \lambda'} = V^{(\alpha, \beta)}_{\kappa, h, 1} |_{\lambda, \lambda'} + V^{(\alpha, \beta)}_{\kappa, h, 2} |_{\lambda, \lambda'},$$

with

$$\left[ V^{(\alpha, \beta)}_{\kappa, h, 1} |_{\lambda, \lambda'} \right]_{\ell, \ell'} = \int_{\Box} \int_{\Box} G_{\kappa, \lambda, \lambda'}(s, t) (\partial_\alpha F_\lambda(s), \partial_\beta F_\lambda(t)) \tilde{\varphi}_{\ell'}(s) \tilde{\varphi}_{\ell}(t) \, ds \, dt \approx \sum_{\|m\|_{\infty} \leq q, \|m'\|_{\infty} \leq q} G_{\kappa, \lambda, \lambda'}(x_m, x_{m'}) (\partial_\alpha F_\lambda(x_m), \partial_\beta F_\lambda(x_{m'})) \cdot \int_{\Box} L_m(s) \tilde{\varphi}_{\ell'}(s) \, ds \int_{\Box} L_{m'}(t) \tilde{\varphi}_{\ell}(t) \, dt$$

for two basis functions $\tilde{\varphi}_{\ell}, \tilde{\varphi}_{\ell'} \in S_{p,J-|\lambda|}(\Box)$. We thus have the representation

$$\left[ V^{(\alpha, \beta)}_{\kappa, h, 1} |_{\lambda, \lambda'} \right]_{\ell, \ell'} = [M_{\lambda}]_{\lambda, \lambda'} (K_{\kappa, \lambda, \lambda'}^{(\alpha, \beta)} (M_{\lambda} M_{\lambda}^T))_{\ell, \ell'},$$

where

$$K_{\kappa, \lambda, \lambda'}^{(\alpha, \beta)}(m_m') = G_{\kappa, \lambda, \lambda'}(x_m, x_m') (\partial_\alpha F_\lambda(x_m), \partial_\beta F_\lambda(x_{m'}))$$

and

$$[M_{\lambda}]_{m, \ell} = \int_0^1 L_{m_1}(s_1) \tilde{\varphi}_{\ell}(s_1) \, ds_1, \quad \tilde{\varphi}_{\ell} \in S_{p,0}([0,1]),$$

$$M_{\lambda} = M_{|\lambda|} \otimes M_{|\lambda|}.$$
Figure 4.3: Illustration of the storage savings for an admissible block \( V_{\kappa,h}^{(\alpha,\beta)} |_{\lambda,\lambda'} \) compressed by the fast multipole method. When using the efficient \( H^2 \)-variant, \( M_{|\lambda|}^{\square} \), and \( M_{|\lambda|}^{\beta,\square} \) can be efficiently represented by recurrence relations such that assembly, storage and application become negligible.

For the second term in (4.7) we obtain
\[
\left[ V_{\kappa,h}^{(\alpha,\beta)} \right]_{\lambda,\lambda'}^{\ell,\ell'} \\
= -\frac{1}{\kappa^2} \int_{\lambda} \int_{\lambda'} G_{\kappa,\lambda,\lambda'}(s,t) \partial_\alpha \hat{\varphi}_{\ell'}(s) \partial_\beta \hat{\varphi}_\ell(t) \, ds \, dt \\
\approx \sum_{\|m\|_\infty \leq q} -\frac{1}{\kappa^2} G_{\kappa,\lambda,\lambda'}(x_m,x_{m'}) \int_{\lambda} L_m(s) \partial_\alpha \hat{\varphi}_{\ell'}(s) \, ds \int_{\lambda'} L_{m'}(t) \partial_\beta \hat{\varphi}_\ell(t) \, dt,
\]
which amounts to the representation
\[
\left[ V_{\kappa,h}^{(\alpha,\beta)} \right]_{\lambda,\lambda'}^{\ell,\ell'} = [M_{|\lambda|}^{\square} K_{\lambda,\lambda'}^{(\alpha,\beta)} (M_{|\lambda'|}^{\beta,\square})^T]_{\ell,\ell'},
\]
with
\[
[M_{|\lambda|}^{\lambda,\lambda'}]_{m,m'} = \int_0^1 L_m(s) \partial_\phi (s) \, ds, \quad \hat{\phi}_\ell \in S_{p,0}^*(\{0,1\}),
\]
\[
M_{|\lambda|}^{\square} = M_{|\lambda|}^{\beta,\square} M_{|\lambda|}^{\lambda,\lambda'},
\]
\[
M_{|\lambda|}^{1,\square} = M_{|\lambda|}^{\lambda,\lambda'} \otimes M_{|\lambda|},
\]
\[
M_{|\lambda|}^{2,\square} = M_{|\lambda|}^{\lambda,\lambda'} \otimes M_{|\lambda|}^{\beta,\square},
\]
and
\[
[K_{\lambda,\lambda'}^{(\alpha,\beta)}]_{m,m'} = -\frac{1}{\kappa^2} G_{\kappa,\lambda,\lambda'}(x_m,x_{m'}).\]

In view of (4.7), this yields the low-rank representation
\[
V_{\kappa,h}^{(\alpha,\beta)} \approx \left[ M_{|\lambda|}^{\square} M_{|\lambda|}^{\alpha,\beta} \right] \left[ K_{\lambda,\lambda'}^{(\alpha,\beta)} \right] \left[ M_{|\lambda'|}^{\beta,\square} \right]^T,
\]
for the matrices (4.5) in all admissible matrix blocks, see also Figure 4.3 for an illustration.

We remark that this representation is within the same framework as it was used for the treatment of the hypersingular operator for the Laplace equation in [19]. Therefore
all considerations made in [19] also apply for our setting here. In particular, there hold the following complexity results, which amount to a linear scaling w.r.t. the number of elements.

**Theorem 4.4.** Let \( N \) denote the number of patches and \( m \) the level of refinement. The storage consumption of the compressed matrix has a complexity of \( O(N \cdot 4^m(pq)^2) \). Moreover, the matrix-vector multiplication has also a complexity of \( O(N \cdot 4^m(pq)^2) \), if its fast \( \mathcal{H}^2 \)-variant is used.

**Remark 4.5.** We stress that the introduced compression scheme has an intrinsic \( \mathcal{H}^2 \)-structure, which is more efficient than the frequently used \( \mathcal{H} \)-matrix structure. Its efficiency is based on the fact that, for each admissible block \( \lambda \times \lambda' \), there are only \( q^2 \) evaluations of the geometry and the kernel function required to assemble the matrices \( K^{(\alpha, \beta)}_{\lambda \lambda', 1} \) and \( K^{(\alpha, \beta)}_{\lambda \lambda', 2} \). The other required matrices from (4.8) can be efficiently represented by recurrence relations from smaller matrices with tensor product structure such that assembly, storage and application become negligible, see [19].

4.3. Error Analysis Of the Compression Scheme. The interpolation of the fundamental solution for the compression of the system matrix introduces an error in the system matrix and, thus, an error in the numerical solution. Since this error depends on the degree of the interpolation \( q \), this section is dedicated to a suitable error analysis. The main application of the following theorem is to bound the approximation error of the bilinear form in a general form of Strang’s first lemma [40, Thm. 4.2.11]. A direct consequence is that the compression scheme is able to maintain the convergence rate predicted by Theorem 3.8, if the polynomial degree for the compression is properly chosen.

**Theorem 4.6 (Error of the Bilinear Form).** Let \( \sigma > 0 \) be arbitrary but fixed and denote by \( m \) the number of uniform refinement steps of \( \square \). Then, for the electric single layer operator \( \mathcal{V}_{\kappa, q} \) which results from an interpolation of degree \( q > 0 \) of the kernel function in every admissible block and the exact representation of the kernel in all other blocks, there holds

\[
\left| \langle \mathcal{V}_k u, v \rangle \times - \langle \mathcal{V}_{k, q} u, v \rangle \times \right| \lesssim 2^{-m}\sigma \| u \|_{H^0(\text{div}, \Gamma)} \| v \|_{H^0(\text{div}, \Gamma)},
\]

provided that \( q \sim (\sigma + 1)m \).

**Proof.** The proof is analogous to the proof of [28, Thm. 5.6], applied separately to both summands of the electric single layer operator.

To apply the previous theorem in Strang’s first lemma, an additional inverse estimate of the kind

\[
\| u_h \|_{H^0(\text{div}, \Gamma)} \lesssim h^{-1/2} \| u_h \|_{H^{-1/2}(\text{div}, \Gamma)}
\]

on the trial spaces is required. For patchwise continuous spline spaces \( S_{p, \mathcal{P}}^1(\Gamma) \) we provide such an estimate in Lemma A.1, but we stress that the error analysis is also valid for other trial spaces providing such an estimate.

We summarize our error analysis in the following theorem, which is a consequence of the considerations in this section and [40, Thm. 4.2.11].

**Theorem 4.7.** The presented compression scheme maintains the existence and uniqueness of the numerical scheme. Moreover the optimal convergence rate of Theorem 3.8 is maintained, if one chooses \( q \sim (s + 5/2)m \).
Figure 5.1: Numerical examples on the unit sphere. Wave number $\kappa = 1$, parameters $q = 10$, and $\eta = 1.6$. The DP-error refers to the maximum error obtained via the manufactured solution of a selection of 100 points on a sphere of radius 3 around the origin. GMRES was restarted every 1500 iterations, with a stopping criterion of $\|r\|_2 \leq 10^{-8}$.

5. Numerical Examples. In the following, we will present a series of numerical examples. A commodity of fast boundary element methods is that they all rely on iterative solvers and, thus, they are likely to struggle with high condition numbers caused by a large ratio of wave number to geometry diameter. Thus, for comparison to other methods, we will indicate both for our test cases. The arising systems are solved via a complex GMRES, without the application of preconditioners, which would be beyond the scope of this paper. The geometry evaluation incorporates Bézier extraction for efficient geometry evaluations. Matrix assembly, matrix-vector multiplication and potential evaluation are parallelized via OpenMP [35].

5.1. Mie Scattering. First, we test the implementation via the computation of the surface current induced by a plane wave from a unit sphere. Here, an analytic solution to the density is known in terms of a series expansion, see [45] for a comprehensive account. Since the energy norm $\|\cdot\|_{H^{-1/2}(\text{div}\Gamma)}$ of the density is not computable explicitly, we choose to compare the $L^2(\Gamma)$-error of the density. In accordance to quasi-optimality of the approach, cf. Theorem 3.8, a convergence of order $p$ is expected, and can indeed be observed, cf. Figure 5.1a.

5.2. The Electric Field as a Quantity of Interest. Although, in contrast to other boundary element methods, c.f. [20], the density obtained in an approach via the electric field integral equation admits a physical interpretation as the surface current, the quantity of interest of scattering problems is mainly the scattered electric field.

Unfortunately, a numerical implementation of the Mie series could not achieve a sufficiently high precision to compare with the high accuracies provided by our isogeometric method. Thus, in order to obtain a reference solution, we employ an

\[ We remark again, that with $p$ we refer to the minimal polynomial degree utilized in the construction of the first space of the discrete sequence (3.3). \]
approach via manufactured solution, i.e., a function that fulfills the electric wave equation in $\Omega^c$ is used to generate the required Dirichlet data. By existence and uniqueness of the solution, cf. [12], one can thus validate the numerical scheme. As such a manufactured solution, we utilize a simple Hertz-Dipole, for which one can check that it fulfills (2.1).

**Definition 5.1 (Hertz-Dipole, [31]).** Let $x_0 \in \Omega^c$ and $p_0 = (0, 0.1, 0.1)$. We define the function

$$DP_{x_0}(x) := e^{i\kappa r} \left( \frac{\kappa^2}{r} (n \times p_0) \times n + \left( \frac{1}{r^3} - \frac{3i\kappa}{r^2} \right) (3n \cdot p_0) - p_0 \right),$$

with $r = \|x - x_0\|$ and $n = (x - x_0)/r$.

Given a reference solution, the errors illustrated in Figure 5.1b validate the convergence rates of the electric field predicted by Corollary 3.9. The last data point of the highest order does not match the predicted order, but is, with an error around $10^{-12}$, close enough to machine accuracy to expect noticeable numerical inaccuracies.

Since the sphere example is a classical benchmark test, we choose to publish detailed data about the computation, specifically in terms of time to solution, in Table 5.1. There, one can also find detailed information about the machine used for computations. This may serve as a reference to compare the presented approach to other implementations, but we stress again that one has to act cautiously when comparing times, since the performance of the fast method depends on various parameters of the problem, in particular, the ratio of the wave number $\kappa$ to the size of the geometry. The input parameters of all computations are detailed in the captions of the corresponding figures.

Also, we note that due to the efficient, element-based approach of the multipole method, the time spend for matrix assembly is negligible compared to the time required for the solution of the linear system, cf. Table 5.1.

### 5.3. Manufactured Solution: Tesla Cavities.

To test more involved geometries with larger numbers of degrees of freedom, we test our boundary element method on the Tesla cavity geometries. They resemble the cavities as used in particle accelerators, for example at DESY [18]. Simulation of electromagnetic fields within such cavities is of enormous practical importance, due to the high manufacturing costs through utilization of superconducting materials. Thus, one aims for accuracies of the simulation that exceed the tolerances that manufacturers can achieve. Boundary element methods are a good fit for these requirements, due to the high convergence order of pointwise values within the domain, cf. [20, Cor. 3.4].

We start these numerical experiments on a single cell of the Tesla cavity, as depicted in Figure 5.2, which resembles a single cell of the full nine-cell cavity. A volumetric discretization is freely available through the geoPDES package of Octave [17]. We extracted the boundary in the form of 34 (one-cell) and 226 (nine-cell) quadratic patches of similar sizes, such that all geometry mappings are smooth due to no interior knot repetitions. On these we apply basis functions of different polynomial degrees, refining uniformly in each refinement step to induce a hierarchical structure, cf. Figure 4.1. The scattering problem is then solved with a right hand side induced by the Dipole for which the precise parameters are presented in Figure 5.3 and Table 5.2. The results are depicted in Figure 5.3.

One can still observe the high convergence rates w.r.t. the number of degrees of freedom. One can also see that the time for matrix assembly, as well as the time to
Figure 5.2: Mesh induced by refinement of level 3 of the Tesla geometries

Figure 5.3: Results for the Tesla 1-Cell geometry. Wave number $\kappa = 18$, manufactured solution $\text{DP}_{(0,0.1,0.1)}$. Admissibility condition with $\eta = 0.1$ and $q = 14$. GMRES restart after 1500 iterations, stopping criterion $\|r\|_2 \leq 10^{-10}$. The $\text{DP}$-error refers to the maximum error obtained via the manufactured solution of a selection of 100 points on a sphere of radius 3 around the origin.
Table 5.1: Detailed data of the unit sphere example with $\kappa = 1$ and $\eta = 1.6$. Computed on a Workstation with Intel(R) Xeon(R) CPU E5-2670 0 @ 2.60GHz, and has been compiled with g++ 5.4, with compile flags -O3 -march=native -fopenmp. Mie-error refers to the error w.r.t. the analytic solution of the scattering problem described in Section 5.1, while the DP-error refers to the error obtained via the manufactured solution as described in Section 5.2, cf. Figures 5.1a and 5.1b. Every 1500 iterations, the GMRES was restarted, with a stopping criterion of $\|r\|_2 \leq 10^{-8}$. Evaluation of the DP-error was done on a set of points scattered across the sphere of radius 3.

|     |                     |          |       | 0.021         | 0.0034      | 0.00012      | 6.69e-06 |

solution, seem to scale independent of the polynomial degree of the discrete functions. However, both the time for matrix assembly and the time to solution differ by a constant factor, favouring solutions obtained via higher order approaches. Moreover, the number of GMRES iterations required for the solution of the system w.r.t. the achieved accuracy of the solution appears to scale completely independent of $p$. This also favors higher-order approaches: For a set accuracy, systems of higher order approaches are smaller due to the higher accuracy per DOF. Thus, an iteration of a matrix-free solver is computationally cheaper.

For the nine-cell example, such clear behavior is not visible, cf. Table 5.2. We attribute this to the fact that the compression parameters (for admissibility condition and order $q$ of the multipole interpolation) had to be chosen such that the problem remained computable on the accessible machines, i.e., one can not depend on the result of Theorem 4.6. Despite the suboptimal choice of parameters, one still can observe
Table 5.2: Detailed data of the sphere example with $\kappa = 10$. Computed on a Workstation, with Intel(R) Xeon(R) CPU E7-8850, and has been compiled with g++ 4.8.5, with compile flags -O3 -march=native -fopenmp. The DP-error refers to the maximum error obtained via the manufactured solution of a selection of 100 points on a sphere of radius 3 around the origin. The stopping criterion for the GMRES was a residual of $||r||_2 < 10^{-10}$, with a restart every 1500 iterations.

that the method converges and yields good results.

6. Conclusion. The solution of electromagnetic scattering problems is an important task in computational engineering. In particular for exterior scattering problems, the idea of boundary element methods plays well together with the idea of isogeometric analysis, since boundary representations of geometries are naturally available from CAD frameworks.

We provided stability assertions for conforming B-spline discretizations for the electromagnetic scattering problems in the multi-patch case. Together with recent approximation results [11], this yields optimal convergence results for the electromagnetic scattering problem. To cope with the arising dense matrices from the discretization, we introduced an interpolation-based fast multipole method, which directly integrates into the isogeometric framework. In particular, and in contrast to other approaches in the literature, it avoids redundant evaluations of kernel and geometry and provides simple means for an efficient $H^2$-matrix implementation, which provides superior complexity properties compared to $H$-matrix implementations. We established relations between the optimal convergence rates and the compression parameters. This shows how the compression parameters must be chosen such that the convergence rates can be maintained.

All theoretical results were confirmed by multiple numerical examples. We provided detailed data about intensive numerical tests and showed that that higher order approaches yield the extremely high orders of convergence, as predicted by the established theory. Moreover, numerical experiments suggest that approaches via higher order B-splines are favorable over lower order approaches, w.r.t. accuracy per DOF and time to solution for the desired accuracy.

Appendix A. Inverse Estimate. For the the conclusion of Theorem 4.7 we require the following inverse estimate for $S^1_{p,\Xi}(\Gamma)$ for discretizations which feature patch-wise continuous spline spaces. Note that inverse estimates for $S^0_{p,\Xi}(\Gamma)$ and $S^2_{p,\Xi}(\Gamma)$ can directly be obtained from standard approximation theory for piecewise polynomials of arbitrary degree.

**Lemma A.1 (Inverse Estimate for $S^1_{p,\Xi}(\Gamma)$).** Let $S^1_{p,\Xi}(\Gamma)$ be patchwise continuous. Then it holds

$$
\|\mathbf{v}_h\|_{H^0(\text{div}\,\Gamma)} \lesssim h^{-1/2} \|\mathbf{v}_h\|_{H^{-1/2}_x(\text{div}\,\Gamma)} \quad \text{for all } \mathbf{v}_h \in S^1_{p,\Xi}(\Gamma).
$$

For the proof we will require some additional knowledge of the space $H^{-1/2}_x(\Gamma)$ and an auxiliary lemma. Therefore, we recall that an equivalent norm on its dual $H^{1/2}_x(\Gamma)$ is given...
by

\[ ||v_h||_{H^1/2(\Gamma)}^2 = \sum_{j \leq N} ||v_h||_{H^1/2(\Gamma_j)}^2 + \sum_{j \leq N} \sum_{i \in \mathcal{I}_j} N_{ij}(v_h), \]

see also [12, 46]. For all \( j \leq N \) we define \( \mathcal{I}_j \) in (A) as the set of the indices of the patches sharing an edge with \( \Gamma_j \). Moreover, we define for all \( j \leq N, i \in \mathcal{I}_j \), the quantity

\[ N_{ij}(v_h) = \int_{\Gamma_i} \int_{\Gamma_j} \frac{|(v_h \cdot \hat{n}_{ij})(x) - (v_h \cdot \hat{n}_{ij})(y)|^2}{||x - y||^3} d\sigma_y d\sigma_x, \]

where, assuming that \( \partial_i F_i = \partial_i F_j \) is the derivative of the parametrization of the common edge \( \Gamma_i \cap \Gamma_j \), we define \( \hat{n}_{ij} \) and \( \hat{n}_{ji} \) such that

\[ \hat{n}_{ij} \cdot i^{-1} (\partial_i F_i) = \left| \int_1^{-1} (\partial_i F_i) \times i^{-1} (\partial_j F_j) \right|_{\mathbb{R}^3}^{-1} \quad \text{on } \Gamma_i, \]

\[ \hat{n}_{ji} \cdot i^{-1} (\partial_j F_j) = \left| \int_1^{-1} (\partial_j F_j) \times i^{-1} (\partial_i F_i) \right|_{\mathbb{R}^3}^{-1} \quad \text{on } \Gamma_j. \]

In short, this means that \( \hat{n}_{ij} \) and \( \hat{n}_{ji} \) are the outward pointing normals on the common patch boundary, scaled by a constant.

The following auxiliary lemma provides an inverse estimate for \( N_{ij}(v_h) \).

**Lemma A.2.** Let \( S^1_{p, \Xi}(\Gamma) \) be patchwise continuous. Then it holds

\[ N_{ij}(v_h) \lesssim h^{-1} ||v_h||_{L^2(\Gamma, \cup \Gamma_j)}^2, \quad \text{for all } v_h \in S^1_{p, \Xi}(\Gamma). \]

**Proof.** For ease of notation we introduce the notation \( \hat{f} := \iota_1(F_j)(f) \) for every \( j \leq N \). Due to the assumptions on the parametrization, it holds

\[ |v_h \cdot \hat{n}_{ij}|_{H^1(\Gamma_i)} \sim |(v_h \cdot \hat{n}_{ij}) \circ F_i|_{H^1(\mathbb{R})} \leq \left| (\hat{v}_h)_1(\hat{n}_{ij})_1 |_{H^1(\mathbb{R})} + |(\hat{v}_h)_2(\hat{n}_{ij})_2 |_{H^1(\mathbb{R})} \right|. \]

In particular, the derivatives of \( \hat{n}_{ij} \) are bounded, such that we can use standard inverse estimates for polynomials to estimate

\[ |v_h \cdot \hat{n}_{ij}|_{H^1(\Gamma_i)} \lesssim \left( |(\hat{v}_h)_1|_{H^1(\mathbb{R})} + |(\hat{v}_h)_2|_{H^1(\mathbb{R})} \right) \lesssim h^{-1} \left( ||\hat{v}_h||_{L^2(\mathbb{R})} + ||\hat{v}_h||_{L^2(\mathbb{R})} \right) \lesssim h^{-1} ||\hat{v}_h||_{L^2(\mathbb{R})} \sim h^{-1} ||v_h||_{L^2(\Gamma_i)}. \]

This yields

\[ |v_h \cdot \hat{n}_{ij}|_{H^1(\Gamma_i, \cup \Gamma_j)} = \sqrt{|v_h \cdot \hat{n}_{ij}|_{H^1(\Gamma_i)}^2 + |v_h \cdot \hat{n}_{ij}|_{H^1(\Gamma_j)}^2} \leq h^{-1} \sqrt{||v_h||_{L^2(\Gamma_i)}^2 + ||v_h||_{L^2(\Gamma_j)}^2} = h^{-1} ||v_h||_{L^2(\Gamma_i, \cup \Gamma_j)}. \]

By exploiting the assumptions on the geometry mappings and \( v_h \cdot \hat{n}_{ij} \leq ||v_h||_{\mathbb{R}^3} ||\hat{n}_{ij}||_{\mathbb{R}^3} \), we moreover conclude

\[ ||v_h \cdot \hat{n}_{ij}||_{L^2(\Gamma_i, \cup \Gamma_j)} \lesssim ||v_h||_{L^2(\Gamma_i, \cup \Gamma_j)}. \]

Adding (C) to (B) and exploiting \( 1 \lesssim h^{-1} \) yields

\[ ||v_h \cdot \hat{n}_{ij}||_{H^1(\Gamma_i, \cup \Gamma_j)} \lesssim h^{-1} ||v_h||_{L^2(\Gamma_i, \cup \Gamma_j)}. \]
We conclude the proof by remarking that the \( \mathbf{L}^2(\Gamma_i \cup \Gamma_j) \)-orthogonal projection \( \Pi_h \) onto \( \mathcal{S}_p \Xi(\Gamma_i \cup \Gamma_j) \) acts as an identity on \( \mathcal{S}_p \Xi(\Gamma_i \cup \Gamma_j) \). Thus, setting \( v_h = \Pi_h v, \ v \in \dot{H}^1_\chi(\text{div}_\Gamma, \Gamma_i \cup \Gamma_j) \), interpolation between (C) and (D) together with
\[
\mathcal{N}_{ij}(v_h) \leq |v_h \cdot \tilde{n}_{ij}|_{H^{1/2}(\Gamma_i \cup \Gamma_j)}^2 \leq \|v_h \cdot \tilde{n}_{ij}\|_{H^{1/2}(\Gamma_i \cup \Gamma_j)}^2
\]
yields the assertion.

We are now in position to prove the required inverse estimate.

**Proof of Lemma A.1.** We recall that the involved norms are given by
\[
\|v_h\|_{\mathbf{L}^2(\text{div}_\Gamma)}^2 = \|v_h\|_{\mathbf{L}^2(\Gamma)}^2 + \|	ext{div}_\Gamma v_h\|_{\mathbf{L}^2(\Gamma)}^2,
\]
\[
\|v_h\|_{\mathbf{H}^{1/2}(\text{div}_\Gamma)}^2 = \|v_h\|_{\mathbf{H}^{1/2}(\Gamma)}^2 + \|	ext{div}_\Gamma v_h\|_{\mathbf{H}^{1/2}(\Gamma)}^2.
\]
Since it holds \( \text{div}_\Gamma v_h \in \mathcal{S}_p \Xi(\Gamma) \) for all \( v_h \in \mathcal{S}_p \Xi(\Gamma) \), and therefore
\[
\|	ext{div}_\Gamma v_h\|_{\mathbf{L}^2(\Gamma)} \lesssim h^{-1/2} \|\text{div}_\Gamma v_h\|_{\mathbf{H}^{1/2}(\Gamma)},
\]
it remains to deal with \( \|v_h\|_{\mathbf{L}^2(\Gamma)} \), for which we will use a duality argument.

Therefore, we remember that an equivalent norm on \( \mathbf{H}^{1/2}_\times(\Gamma) \) is given by (A). Standard inverse estimates for piecewise polynomials in each component yield
\[
\sum_{j \leq N} \|v_h\|_{H^{1/2}(\Gamma_j)}^2 \lesssim h^{-1} \sum_{j \leq N} \|v_h\|_{\mathbf{L}^2(\Gamma_j)}^2,
\]
whereas Lemma A.2 allows to estimate
\[
\sum_{j \leq N+i \in I_j} \mathcal{N}_{ij}(v_h) \lesssim h^{-1} \sum_{j \leq N+i \in I_j} \|v_h\|_{\mathbf{L}^2(\Gamma_j \cup \Gamma^i)}^2 \lesssim h^{-1} \|v_h\|_{\mathbf{L}^2(\Gamma)}^2.
\]
This yields
\[
\|v_h\|_{\mathbf{H}^{1/2}_\times(\Gamma)} \lesssim h^{-1/2} \|v_h\|_{\mathbf{L}^2(\Gamma)}, \quad \text{for all } v_h \in \mathcal{S}_p \Xi(\Gamma).
\]

Using the \( \mathbf{L}^2(\Gamma) \)-orthogonal projection \( \Pi_h \) onto \( \mathcal{S}_p \Xi(\Gamma) \), we can now use a duality argument to arrive at
\[
\|v_h\|_{\mathbf{L}^2(\Gamma)} = \sup_{\|w\|_{\mathbf{L}^2(\Gamma)} = 1} \langle v_h, w \rangle_{\times}
\]
\[
= \sup_{\|w\|_{\mathbf{L}^2(\Gamma)} = 1} \langle v_h, \Pi_h w \rangle_{\times}
\]
\[
= \|v_h\|_{\mathbf{H}^{-1/2}_\times(\Gamma)} \sup_{\|w\|_{\mathbf{L}^2(\Gamma)} = 1} \|\Pi_h w\|_{\mathbf{H}^{1/2}_\times(\Gamma)} \lesssim h^{-1/2} \|v_h\|_{\mathbf{H}^{-1/2}_\times(\Gamma)},
\]
In the last step we used the previously derived inverse estimate (E) and the stability of the \( \mathbf{L}^2(\Gamma) \)-projection. This yields the assertion. \( \Box \)
