AN ELEMENTARY APPROACH TO UNIFORM IN TIME PROPAGATION OF CHAOS

ALAIN DURMUS, ANDREAS EBERLE, ARNAUD GUILLIN, RAPHAEL ZIMMER

Abstract. Based on a coupling approach, we prove uniform in time propagation of chaos for weakly interacting mean-field particle systems with possibly non-convex confinement and interaction potentials. The approach is based on a combination of reflection and synchronous couplings applied to the individual particles. It provides explicit quantitative bounds that significantly extend previous results for the convex case.

1. Introduction

Let $V, W : \mathbb{R}^d \to \mathbb{R}$ be twice continuously differentiable functions satisfying appropriate regularity and growth conditions. We consider the kinetic Fokker-Planck equation

$$\partial_t \mu_t = \nabla \cdot [\nabla \mu_t + (\nabla V + \nabla W \ast \mu_t) \mu_t] \tag{1}$$

and its probabilistic counterpart, the nonlinear stochastic differential equation

$$d\tilde{X}_t = -\nabla V(\tilde{X}_t) \, dt - \nabla W \ast \mu_t(\tilde{X}_t) \, dt + \sqrt{2} \, dB_t , \quad \mu_t = \mathcal{L}(\tilde{X}_t) \tag{2},$$

of McKean-Vlasov type. Here $\mu_t$ is a time dependent probability measure on $\mathbb{R}^d$ and $\ast$ denotes the standard convolution operator. The function $V$ corresponds to a confinement potential and the function $W$ to an interaction potential. Variants of the equation occur for example in the modelling of granular media, cf. [1, 34].

Both in the probability and in the p.d.e. community, existence and uniqueness of (1) and (2) have attracted much attention, see [23, 16, 29, 24] for a few milestones, and [27] and [17] for two recent results. During the last twenty years, there has been a lot of progress on convergence to equilibrium of solutions $(\mu_t)_{t \geq 0}$ of (1). Carrillo, McCann and Villani [7, 8] have proven an exponential convergence rate under the strict convexity condition $\text{Hess}(V + 2W) \geq \rho \text{Id}$ with $\rho > 0$. They have also established a polynomial convergence rate in the case where $V + 2W$ is only degenerately strictly convex with $\text{Hess}(V + 2W)(x) = 0$ for some isolated points $x \in \mathbb{R}^d$. Malrieu [22] and Cattiaux et al. [11] have developed a probabilistic approach to these results that is based on an approximation by the mean-field particle system which is defined for $N \in \mathbb{N}$ as the solution of the equations

$$dX_t^{i,N} = -\nabla V(X_t^{i,N}) \, dt - N^{-1} \sum_{j=1}^{N} \nabla W(X_t^{i,N} - X_t^{j,N}) \, dt + \sqrt{2} dB_t^{i} , \quad i = 1, \ldots, N, \tag{3}$$

where the initial values $X_0^1, \ldots, X_0^N$ are i.i.d. random variables, and the processes $(B_t^{1})_{t \geq 0}, \ldots, (B_t^{N})_{t \geq 0}$ are independent Brownian motions. It is well-known [29, 24] that under
weak assumptions on $V$ and $W$, the laws of the particles at time $t$ converge to the solution $\mu_t$ of (1) as $N \to \infty$. In [22, 11], both convergence to equilibrium for the nonlinear SDE (2) and uniform in time propagation of chaos for the particle system have been proven under convexity assumptions by using functional inequalities and synchronous couplings, respectively.

When $V + 2W$ is not convex, the situation is much more delicate. Uniqueness of a stationary solution of (1) does not hold in general without additional conditions on $V$ and $W$. Even in this case, only few results on convergence to equilibrium are known. By a direct study of the dissipation of the Wasserstein distance, Bolley, Gentil and Guillin [2] established an exponential trend to equilibrium in a weakly non-convex case. In a recent work by three of the authors [14], an exponential contraction property and thus convergence to equilibrium could be shown for a much broader class of potentials. The proof is based on a new coupling approach originating in [13], which is also the basis of this work. An interesting related problem arises when there are multiple invariant measures, see [30]. In this widely open case, a main interest are the relative basins of attraction of the equilibria.

The convergence of the empirical measure of the particle system (3) to the solution of (1), or, equivalently, the convergence of the pair empirical measure to the tensor product of two solutions of (1), has been stated under the name of propagation of chaos by Kac [20], and further developed by Sznitman [29]. However, the corresponding general results are only valid uniformly for a fixed time horizon. A crucial point is then not only to assert the convergence of the empirical measures but to quantify it. A remarkable analytic framework providing also quantitative propagation of chaos estimates has been developed by Mischler, Mouhot and their coauthors in connection with Kac’s program in kinetic theory [25, 18, 26].

In this article, we propose a very different and much more elementary, probabilistic approach to quantitative bounds for propagation of chaos. Our main result is a uniform in time propagation of chaos bound that takes the form

$$W^{\ell_1}(f) \left( \mathcal{L}(X^{1,N}_t, \ldots, X^{N,N}_t), \mu^\otimes N \right) \leq A \cdot N^{-1/2}$$

for all $t \geq 0$ and $n \in \mathbb{N}$, if $X^{1}_0, \ldots, X^{n}_0$ are i.i.d. with initial law $\mu_0$, see Theorem 2 below. Here $W^{\ell_1}(f)$ is an $L^1$ Wasserstein distance on $(\mathbb{R}^d)^N$ and $A$ is an explicit finite constant, see below for the precise definitions. The bound holds under similar assumptions as the quantitative bounds on convergence to equilibrium for McKean-Vlasov equations in [14]. In particular, it applies in non-convex cases provided the confinement potential $V$ is strictly convex outside a ball, and the interaction potential $W$ is symmetric and globally Lipschitz continuous with sufficiently small Lipschitz constant. Consequently, our results are significant extensions of the uniform in time propagation of chaos results in the convex case in [22, 11]. The main difference to the approach in these works is that we use a more refined coupling which is harder to analyse but much more powerful than synchronous coupling. The second main ingredient in our proofs is an adequately constructed $L^1$ Wasserstein distance that is well adapted to the couplings we consider. Our probabilistic approach is very different from the analytic methods developed in [25, 18, 26], and the conditions required are not easily comparable. One advantage of the coupling approach presented
here is that it is very simple and quite robust. This might facilitate the application to other classes of models. For example, the same argument can be applied immediately if \(\nabla V\) is replaced by a non-gradient drift \(\beta\) that satisfies corresponding assumptions. Similarly, \(\nabla W\) can be replaced by a more general interaction term, see Remark 4 below.

In Section 2, we present our main hypotheses and results concerning the uniform in time propagation of chaos. The proofs are provided in Section 3. Our approach is based on an interplay between reflection and synchronous coupling. It relies heavily on the framework introduced in [13, 14]. Our results use properties of the confinement potential, which may nevertheless possess many wells. The interactions are mainly seen as a perturbation. An interesting and challenging problem to be taken up in forthcoming work is to prove propagation of chaos in situations where \(V = 0\) and \(W\) is not convex, but uniqueness of a stationary distribution holds.

### 2. Uniform in time propagation of chaos

In this section we state our main results. We will first state the precise assumptions on the potentials \(V\) and \(W\). Moreover, we define some functions and parameters that will determine the particular Wasserstein distance that we consider.

#### 2.1. Hypotheses and definitions.

We first state our assumption on the confinement potential.

**H1.** There is a continuous function \(\kappa : [0, \infty) \to \mathbb{R}\) satisfying \(\liminf_{r \to \infty} \kappa(r) > 0\) such that

\[
\langle \nabla V(x) - \nabla V(y), x - y \rangle \leq \kappa(\|x - y\|) \|x - y\|^2 \quad \text{for all } x, y \in \mathbb{R}^d .
\]

Note that under H1, there exist \(m_V > 0\) and \(M_V \geq 0\) such that for all \(x, y \in \mathbb{R}^d\),

\[
\langle \nabla V(x) - \nabla V(y), x - y \rangle \geq m_V \|x - y\|^2 - M_V .
\]

Following the framework introduced in [13], we now define constants \(R_0\) and \(R_1\) as

\[
R_0 := \inf \{s \in \mathbb{R}_+ : \kappa(r) \geq 0 \text{ for all } r \geq s\} ,
\]

\[
R_1 := \inf \{s \geq R_0 : s(s - R_0)\kappa(r) \geq 8 \text{ for all } r \geq s\} ,
\]

and we consider the functions \(\varphi, \Phi, g : \mathbb{R}_+ \to \mathbb{R}_+\) defined by

\[
\varphi(r) = \exp \left( -\frac{1}{4} \int_0^r s \kappa_-(s) ds \right) , \quad \Phi(r) = \int_0^r \varphi(s) ds ,
\]

\[
g(r) = 1 - \frac{c}{2} \int_0^{r \wedge R_1} \Phi(s) \varphi^{-1}(s) ds ,
\]

where \(\kappa_- = \max(0, -\kappa)\), and

\[
c = \frac{1}{\int_0^{R_1} \Phi(s) \varphi^{-1}(s) ds} .
\]

Note that \(\varphi(r) = \varphi(R_0)\) for \(r \geq R_0\), and \(g(r) = 1/2\) for \(r \geq R_1\). In addition, for all \(r \in \mathbb{R}_+\), \(g(r) \in [1/2, 1]\). We now define an increasing function \(f : [0, \infty) \to [0, \infty)\) by

\[
f(r) = \int_0^r \varphi(s) g(s) ds .
\]
Since \( \varphi \) and \( g \) are decreasing, \( f \) is concave, for all \( r \geq 0 \),

\[
(12) \quad \varphi(R_0)r/2 \leq \Phi(r)/2 \leq f(r) \leq \Phi(r) \leq r .
\]

Note that by (12), \((x,y) \mapsto f(||x-y||)\) induces a distance that is equivalent to the Euclidean distance on \( \mathbb{R}^d \). Below, we will use contraction properties in \( L^1 \) Wasserstein distances based on the underlying distance \( f(||x-y||) \). These contraction properties will be a consequence of the inequality

\[
(13) \quad f''(r) - r\kappa(r)f'(r)/4 \leq -cf(r)/2 \quad \text{for all } r \in \mathbb{R}_+ \setminus \{R_1\} .
\]

Indeed, notice that (13) is satisfied for \( r \in [0, R_1) \) by the definitions and since \( f \leq \Phi \). Moreover, for \( r > R_1 \), \( f(r) = f(R_1) + \varphi(R_0)(r - R_1)/2 \), and thus by definition of \( R_1 \),

\[
f''(r) - r\kappa(r)f'(r)/4 = -r\kappa(r)\varphi(R_0)/8 \leq -r(R_1(R_1 - R_0))^{-1}\varphi(R_0)
\]

\[
\leq -\Phi(r)(\Phi(R_1)(R_1 - R_0))^{-1}\varphi(R_0) \leq \frac{1}{2}\Phi(r)/\int_{R_0}^{R_1} \Phi(s)\varphi^{-1}(s)ds \leq -cf(r)/2 .
\]

Here we have used that for \( r \geq R_0 \), \( \varphi \) is constant, \( \Phi(r) = \Phi(R_0) + (r - R_0)\varphi(R_0) \), and

\[
\int_{R_0}^{R_1} \Phi(s)\varphi(s)^{-1}ds = \Phi(R_0)\varphi(R_0)^{-1}(R_1 - R_0) + (R_1 - R_0)^2/2
\]

\[
\geq (R_1 - R_0)(\Phi(R_0) + (R_1 - R_0)\varphi(R_0))\varphi(R_0)^{-1}/2 = (R_1 - R_0)\Phi(R_1)\varphi(R_0)^{-1}/2 .
\]

Next, we state the assumptions on the interaction potential.

**H2.**

(i) \( W \) is symmetric, i.e., \( W(x) = W(-x) \) for all \( x \in \mathbb{R}^d \).

(ii) There exists \( \eta \in (0, c) \) such that for all \( x, y \in \mathbb{R}^d \),

\[
||\nabla W(x) - \nabla W(y)|| \leq \eta f(||x - y||) ,
\]

where \( f \) and \( c \) are defined by (11) and (10).

Notice that by (12), a sufficient condition for H2-(ii) is that \( \nabla W \) is \( L \)-Lipschitz continuous, with \( L < 2c/\varphi(R_0) \). By H2-(i), \( \nabla W(0) = 0 \). Thus, since \( f' \leq 1 \), H2 implies

\[
||\nabla W(x)|| \leq \eta \|x\| .
\]

We consider also the following additional condition:

**H3.** There exists \( M_W \in [0, \infty) \) such that for all \( x, y \in \mathbb{R}^d \),

\[
(\nabla W(x) - \nabla W(y), x - y) \geq -M_W .
\]

Under H1 and H2, the equations (2) and (3) both have unique strong solutions \((\bar{X}_t)_{t \geq 0}\) and \((\{X^i_t\}_{t \geq 0}, i = 1, \ldots, N)\) if we suppose sufficient integrability assumptions on the initial measures (say moments of order 4), see e.g. [11, Theorem 2.6]. In addition,

\[
\sup_{t \in [0, T]} \mathbb{E} \left( \|\bar{X}_t\|^2 + \|X^i_t\|^2 \right) < \infty \quad \text{for all } T \geq 0 .
\]

**Example 1** (Double-well potential). A natural example which satisfies the assumptions above is the case of a double well confinement potential with quadratic interaction

\[
V(x) = ||x||^4 - a||x||^2, \quad W(x) = \pm ||x||^2, \quad a > 0 ,
\]

where the sign of the interaction implies attractiveness or repulsion. Using [13, Lemma 1 and Example 4], one has that the constant \( c \) in (13), which is crucial for the rate of
convergence to equilibrium, is of order $\Theta(1)$ for small $a$, whereas for large $a$, $\log(c^{-1})$ is of order $\Theta(a^2)$.

2.2. Main results. Let $\mathcal{W}_f$ denote the Kantorovich ($L^1$ Wasserstein) distance on probability measures based on the underlying distance function $f(\|x - y\|)$ on $\mathbb{R}^d$, i.e.,

$$
\mathcal{W}_f(\nu, \mu) = \inf_{\xi \in \Pi(\nu, \mu)} \int_{\mathbb{R}^d \times \mathbb{R}^d} f(\|x - y\|) \, d\xi(x, y),
$$

where $\Pi(\nu, \mu)$ is the set of couplings of $\mu$ and $\nu$, i.e., probability measures $\xi$ on $\mathcal{B}(\mathbb{R}^d \times \mathbb{R}^d)$ such that for all $A \in \mathcal{B}(\mathbb{R}^d)$, $\xi(A \times \mathbb{R}^d) = \mu(A)$ and $\xi(\mathbb{R}^d \times A) = \nu(A)$. In the case where $f$ is the identity function $f(r) \equiv r$, $\mathcal{W}_f$ is the usual $L^1$ Wasserstein distance $\mathcal{W}_1$. We also consider corresponding Kantorovich distances on probability measures $\hat{\nu}$, $\hat{\mu}$ on the configuration space $(\mathbb{R}^d)^N$. Here we set

$$
\mathcal{W}_{i(f)}(\hat{\nu}, \hat{\mu}) = \inf_{\xi \in \Pi(\hat{\nu}, \hat{\mu})} \int_{\mathbb{R}^d \times \mathbb{R}^d} \frac{1}{N} \sum_{i=1}^{N} f(\|x^i - y^i\|) \, d\xi(x, y).
$$

For $t \geq 0$ and $\nu, \mu \in \mathcal{P}(\mathbb{R}^d)$, we denote by $\hat{\mu}_t^\nu$ and $\mu_t^{\nu,N}$ the laws of $\hat{X}_t$ and $X_t^{\nu,N}$, for an arbitrary $i$, with initial distributions $\nu$ and $\mu$ ($\mu$ being the common distribution of the i.i.d. random variables $X_0^{\nu,N}$, $i \in \{1, \ldots, N\}$. We now state our main result.

**Theorem 2.** Assume $H1$ and $H2$, and suppose that $H3$ is satisfied or $\eta \in (0, m_V/2)$, where $m_V$ is given by (5). Let $\nu$ and $\mu$ be probability measures on $(\mathbb{R}^d, \mathcal{B}(\mathbb{R}^d))$ which admit a finite fourth moment. Then for all $t \geq 0$ and $N \in \mathbb{N}$, we have

$$
\mathcal{W}_f(\mu_t^{\nu,N}, \hat{\mu}_t^\nu) \leq e^{-2(c-\eta)t} \mathcal{W}_f(\nu, \mu) + (2(c-\eta))^{-1} C \eta N^{-1/2},
$$

and, more generally,

$$
\mathcal{W}_{i(f)}(\mathcal{L}(X_t^{1,N}, \ldots, X_t^{N,N}), (\hat{\mu}_t^\nu)^{\otimes N}) \leq e^{-2(c-\eta)t} \mathcal{W}_f(\nu, \mu) + (2(c-\eta))^{-1} C \eta N^{-1/2}.
$$

Here $f$ and $c$ are defined by (11) and (10), respectively, and $C$ is a constant that depends only on the dimension $d$, the second moment of $\nu$, as well as $V$ and $W$.

By (12) and the definition of $\mathcal{W}_f$, we immediately obtain:

**Corollary 3.** Under the same hypotheses as in Theorem 2, for all $t \geq 0$ and $N \in \mathbb{N}$,

$$
\mathcal{W}_{i(f)}(\mu_t^{\nu,N}, \hat{\mu}_t^\nu) \leq 2 \varphi(R_0)^{-1} e^{-2(c-\eta)t} \mathcal{W}_f(\nu, \mu) + (\varphi(R_0)(c-\eta))^{-1} C \eta N^{-1/2},
$$

where $R_0$ and $\varphi$ are defined by (6) and (8), respectively, and $C$ is a constant only depending on $d$, the second moment of $\nu$, as well as $V$ and $W$.

The dependence of the bounds on $N$ is of the right order and consistent with both the non uniform in time estimates, and the uniform in time bounds under uniform strict convexity for $L^2$ Wasserstein distances obtained for example in [29, 22].

**Remark 4.** For the sake of clarity and comparison with other recent works on uniform propagation of chaos [22, 11], we have restricted ourselves to interaction drifts of the type $b(x, \mu) = -\nabla W * \mu$. Similarly to [14], the present result can be extended to $b(x, \mu) = \int b(x, y) \mu(dy)$ if $b$ satisfies a Lipschitz condition with sufficiently small Lipschitz constant. Similarly, the confinement drift $-\nabla V$ can be replaced by a non-gradient drift satisfying a corresponding assumption as $H1$. 

Remark 5. In [7, 22, 11], it has been shown that for a fixed center of mass, exponential contractivity of the nonlinear SDE and uniform propagation of chaos hold if $V + 2W$ is, for example, strictly uniformly convex. This suggests that convexity of the interaction potential $W$ can make up for non-convexity of $V$, a fact that is not visible from our current approach. The problem is that a symmetrization trick is used to get a benefit from the convexity of the interaction potential. This trick does not carry over in the same form to the $\ell_1$ type distances considered here. We will address this challenging issue in a future work.

Remark 6. By combining the result of Theorem 2 and the contraction result for mean-field particle systems in [13, Corollary 3.4], one can derive a contraction result for the non-linear equation (1), recovering essentially [14, Theorem 2.3].

3. Proofs

The proof of the main result is based on three ingredients. As usual, the starting construction is to consider i.i.d. copies of the nonlinear process and to couple them with the system of particles. This will be done by considering a reflection coupling coordinate by coordinate. The second ingredient will then be to consider a specific Kantorovich ($L^1$ Wasserstein) distance based on an $\ell_1$ type metric on the product space that is particularly suited to this coupling. The last ingredient is a law of large numbers type control in $\ell_1$ Wasserstein) distance based on an $\ell_1$ type distances considered here. We will address this challenging issue in a future work.

3.1. Coupling by reflection. For every $\delta > 0$, we consider Lipschitz continuous functions $\phi^\delta, \Phi^\delta : \mathbb{R}^d \to \mathbb{R}$ satisfying

\[
(\phi^\delta)^2(x) + (\phi^\delta)^2(x) = 1 \quad \text{for all } x \in \mathbb{R}^d, \quad \phi^\delta(x) = \begin{cases} 
1 & \text{if } \|x\| \geq \delta, \\
0 & \text{if } \|x\| \leq \delta/2.
\end{cases}
\]

Now fix $\delta > 0$, probability measures $\nu, \mu$ on $\mathbb{R}^d$ with finite fourth moment, and a coupling $\xi \in \Pi(\nu, \mu)$. We consider the coupling between the independent nonlinear processes and the mean-field particle system defined by the following system of stochastic differential equations:

\[
\begin{align*}
\dd X^i_s &= -\nabla V(X^i_s)ds - \nabla W \ast \mu^\nu_s(X^i_s)ds + \sqrt{2} \left\{ \phi^\delta(E^i_s)dB^i_s + \phi^\delta(E^i_s)d\bar{B}^i_s \right\}, \\
\dd X^{i,N}_s &= -\nabla V(X^{i,N}_s)ds - \frac{1}{N} \sum_{j=1}^N \nabla W(X^{i,N}_s - X^{j,N}_s)ds \\
&\quad + \sqrt{2} \left\{ \phi^\delta(E^i_s) (1d - 2e^i_s(e^i_s)^T) dB^i_s + \phi^\delta(E^i_s)d\bar{B}^i_s \right\}.
\end{align*}
\]

Here we assume that $(X^i_0, X^{i,N}_0)$, $i \in \{1, \ldots, N\}$, are independent standard Brownian motions in $\mathbb{R}^d$ that are also independent of the initial conditions, and

\[
E^i_s = X^i_s - X^{i,N}_s, \quad e^i_s = \eta(E^i_s),
\]

where $\eta : \mathbb{R}^d \to \mathbb{R}^d$ is given for all $x \in \mathbb{R}^d \setminus \{0\}$ by $\eta(x) = x/\|x\|$, and $\eta(0) = 0$. 

Under the fourth moment assumption on $\nu$ and $\mu$, the system of SDEs has a unique strong solution. This can be shown similarly to [11, Theorem 2.6]. By (16) and Lévy’s characterization of Brownian motion, the process \( ((\bar{X}_i^1, \ldots, \bar{X}_i^N)_{t \geq 0}, (X_t^{1,N}, \ldots, X_t^{N,N})_{t \geq 0}) \) is indeed a realization of a coupling between the system of independent nonlinear diffusions with initial law $\nu^{\otimes N}$ and the mean-field particle system with initial law $\mu^{\otimes N}$. In particular,

\begin{equation}
\bar{\mu}_t^i = \mathcal{L}(\bar{X}_i^1) \quad \text{and} \quad \mu_t^{i,N} = \mathcal{L}(X_t^{1,N}) \quad \text{for all } t \geq 0 \text{ and } i \in \{1, \ldots, N\}.
\end{equation}

**Lemma 7.** Assume $H1$ and $H2$. Then almost surely, for all $t \geq 0$ and $i \in \{1, \ldots, N\}$,

\[ d\left\| E_t^i \right\|^2 = -2 \left( \nabla V(\bar{X}_i^t) - \nabla V(X_t^{1,N}), E_t^i \right) dt - \frac{1}{N} \sum_{j=1}^N \nabla W(X_t^{i,N} - X_t^{j,N}), E_t^i \right) dt + 4\sqrt{2} \phi_t^\epsilon(E_t^i) (e_i^1, e_i^2)^T dB_t^i,
\]

where \((A_t^i)_{t \geq 0}\) is an adapted stochastic process such that

\begin{equation}
A_t^i \leq \left\| \nabla W * \hat{\mu}_t^i(\bar{X}_i^t) - \frac{1}{N} \sum_{j=1}^N \nabla W(X_t^{i,N} - X_t^{j,N}) \right\|.
\end{equation}

**Proof.** For all $i \in \{1, \ldots, N\}$, using Itô’s formula, we have

\[ d\left\| E_t^i \right\|^2 = -2 \left( \nabla V(\bar{X}_i^t) - \nabla V(X_t^{1,N}), E_t^i \right) dt - 2 \left( \nabla W * \hat{\mu}_t^i(\bar{X}_i^t) - N^{-1} \sum_{j=1}^N \nabla W(X_t^{i,N} - X_t^{j,N}), E_t^i \right) dt + 4\sqrt{2} \phi_t^\epsilon(E_t^i) (e_i^1, e_i^2)^T dB_t^i.
\]

Now let $a > 0$, and consider the function $\psi_a(r) = (r + a)^{1/2}$ for $r \geq 0$. Note that $\psi_a$ is infinitely continuously differentiable on $(0, \infty)$, and for all $t \geq 0$, $\lim_{a \to 0} \psi_a(t) = t^{1/2}$.

Therefore, using again Itô’s formula, we get

\[ d\psi_a \left( \left\| E_t^i \right\|^2 \right) = -2\psi_a' \left( \left\| E_t^i \right\|^2 \right) \left( \nabla V(\bar{X}_t^i) - \nabla V(X_t^{1,N}), E_t^i \right) dt - 2\psi_a' \left( \left\| E_t^i \right\|^2 \right) \left( \nabla W * \hat{\mu}_t^i(\bar{X}_t^i) - N^{-1} \sum_{j=1}^N \nabla W(X_t^{i,N} - X_t^{j,N}), E_t^i \right) dt + \phi_t^\epsilon(E_t^i) (e_i^1, e_i^2)^T dB_t^i.
\]

Note that $2r\psi_a'(r^2) = r/\sqrt{r^2 + a} \leq 1/2$ for all $a, r > 0$. In particular,

\[ \left| 2\psi_a' \left( \left\| E_t^i \right\|^2 \right) \left( \nabla V(\bar{X}_t^i) - \nabla V(X_t^{1,N}), E_t^i \right) \right| \leq \left\| \nabla V(\bar{X}_t^i) - \nabla V(X_t^{1,N}) \right\|.
\]

Therefore, by dominated convergence, we see that that almost surely for all $T \geq 0$,

\[ \lim_{a \to 0} \int_0^T 2\psi_a' \left( \left\| E_t^i \right\|^2 \right) \left( \nabla V(\bar{X}_t^i) - \nabla V(X_t^{1,N}), E_t^i \right) dt = \int_0^T \left( \nabla V(\bar{X}_t^i) - \nabla V(X_t^{1,N}), E_t^i \right) dt.
\]

Furthermore, for any $a > 0$, the term in (20) is bounded from above by the expression on the right hand side of (19). Moreover, noting that $\phi_t^\epsilon(z) = 0$ for $z \in \mathbb{R}^d$ with $\|z\| \leq \delta/2$, and $8\psi_a'(r^2) + 16\psi_a''(r^2) = 4a/(r^2 + a)^{3/2} \leq 4a/r^3$ for $a, r > 0$, we see that for $T \geq 0$,

\[ \lim_{a \to 0} \int_0^T (\phi_t^\epsilon(E_t^i))^2 \left( 8\psi_a \left( \left\| E_t^i \right\|^2 \right) + 16 \left\| E_t^i \right\|^2 \psi_a'' \left( \left\| E_t^i \right\|^2 \right) \right) dt = 0.
\]
Finally, by [28, Theorem 2.12], we have almost surely
\[
\lim_{a \to 0} \int_0^T 4\sqrt{2} \psi_a \left( \left\| E_t^i \right\|^2 \right) \phi_t^i(E_t^i) \langle e_t^i, E_t^i \rangle (e_t^i)^T dB_t^i = \int_0^T 2\sqrt{2} \phi_t^i(E_t^i)(e_t^i)^T dB_t^i, 
\]
for any \( T \geq 0 \). This completes the proof of the lemma. \( \square \)

3.2. \textbf{A moment control.} The following uniform moment bound will be important for the proof of our main result.

\textbf{Lemma 8.} Assume \( H1 \) and \( H2 \), and suppose that \( \eta \in (0, m_V/2) \) or Assumption \( H3 \) is satisfied. Let \((\tilde{X}_t)_{t \geq 0}\) be a solution of (2) with \( \mathbb{E} \left[ \left\| X_0 \right\|^2 \right] < \infty \). Then there exists \( C \in (0, \infty) \) depending only on \( d, V, W \) and the second moment of \( X_0 \) such that
\[
\sup_{t \geq 0} \mathbb{E} \left[ \left\| \tilde{X}_t \right\|^2 \right] \leq C. 
\]

\textit{Proof.} The proof is quite standard but we include it here for completeness. First, by Itô’s formula, we have
\[
(1/2)d\left\| \tilde{X}_t \right\|^2 = -\langle \tilde{X}_t, \nabla V(\tilde{X}_t) \rangle dt - \langle \tilde{X}_t, \nabla W * \hat{\mu}_t(\tilde{X}_t) \rangle dt + d dt + \sqrt{2} \tilde{X}_t^T dB_t, 
\]
where \( \nu \) denotes the law of \( X_0 \). Let \((\tilde{X}_t)_{t \geq 0}\) be an independent copy of \((\tilde{X}_t)_{t \geq 0}\). Then by symmetrization and (15), we get taking the expectation that
\[
\frac{d}{dt} \mathbb{E} \left[ \left\| \tilde{X}_t \right\|^2 \right] = -2 \mathbb{E} \left[ \langle \tilde{X}_t, \nabla V(\tilde{X}_t) \rangle \right] - \mathbb{E} \left[ \langle \tilde{X}_t - \tilde{X}_t, \nabla W(\tilde{X}_t - \tilde{X}_t) \rangle \right] + 2d. 
\]
Now suppose first that \( H1 \), \( H2 \) and \( H3 \) are satisfied. Then by (5) and since \( \nabla W(0) = 0 \),
\[
\frac{d}{dt} \mathbb{E} \left[ \left\| \tilde{X}_t \right\|^2 \right] \leq 2M_V + M_W + 2d - 2m_V \mathbb{E} \left[ \left\| \tilde{X}_t \right\|^2 \right] + 2 \left\| \nabla V(0) \right\| \mathbb{E} \left[ \left\| \tilde{X}_t \right\|^2 \right]^{1/2}. 
\]
Hence Gronwall’s lemma concludes the proof.

Alternatively, assume only that \( H1 \) and \( H2 \) are satisfied. Since \( f(r) \leq r \), we obtain
\[
\frac{d}{dt} \mathbb{E} \left[ \left\| \tilde{X}_t \right\|^2 \right] \leq 2M_V + 2d + (\eta - m_V) \mathbb{E} \left[ \left\| \tilde{X}_t \right\|^2 \right] + 2 \left\| \nabla V(0) \right\| \mathbb{E} \left[ \left\| \tilde{X}_t \right\|^2 \right]^{1/2}. 
\]
Hence for \( \eta < m_V/2 \), we can still apply Gronwall’s lemma to conclude the proof. \( \square \)

3.3. \textbf{Proof of main results.} We can now prove our main result.

\textit{Proof of Theorem 2.} We fix \( \delta > 0 \) and a coupling \( \xi \in \Pi(\nu, \mu) \), and we consider the reflection coupling with initial law \( \xi^\otimes N \) between the system of nonlinear processes and the mean-field particle system as introduced in Subsection 3.1. Since \( f \) is continuously differentiable and \( f' \) is absolutely continuous, by Lemma 7 and the Itô-Tanaka formula, we obtain
\[
df(\|E_t^i\|) = (C_t^i + A_t^i) f'(\|E_t^i\|) dt + 4f''(\|E_t^i\|) (\phi_t^i(E_t^i))^2 dt + \sqrt{2} \phi_t^i(E_t^i)(e_t^i)^T dB_t^i,
\]
where \( C_t^i = -\langle \nabla V(\tilde{X}_t^i) - \nabla V(X_t^{i,N}), e_t^i \rangle \). Define \( \omega : \mathbb{R}_+ \to \mathbb{R}_+ \) by
\[
\omega(r) = \sup_{s \in [0, r]} s \kappa(s)^{-}. 
\]

(23)
By definition of $\kappa$ given by (4), and by (13),

\begin{align}
C_i f'(E_i^t) + 4f''(E_i^t) (\phi^i_t(E_i^t))^2 \\
&\geq - \kappa(E_i^t) f'(E_i^t) + 4f''(E_i^t) (\phi^i_t(E_i^t))^2 \\
&\leq -2c f(E_i^t) (\phi^i_t(E_i^t))^2 + \omega(\delta) \\
&\leq -2c f(E_i^t) + \omega(\delta).
\end{align}

Moreover, by (19), we can estimate $A_i^t \leq N^{-1} \sum_{j=1}^N \Xi_{i,j}^t + \Upsilon_i^t$, where

\begin{align}
\Xi_{i,j}^t &= \left\| \nabla W(\bar{X}^{i,N}_t - \bar{X}^{j,N}_t) - \nabla W(X^{i,N}_t - X^{j,N}_t) \right\|, \\
\Upsilon_i^t &= \left\| \nabla W(\bar{X}^{i}_t) - N^{-1} \sum_{j=1}^N \nabla W(\bar{X}^{i}_t - \bar{X}^{j}_t) \right\|.
\end{align}

Therefore, and since $\int_0^t \phi^i_s(e_i^s)^T dB_s^i$ is a martingale and $f' \leq 1$, we obtain

\begin{equation}
\frac{1}{N} \sum_{i=1}^N \frac{d}{dt} \mathbb{E} \left[ f(E_i^t) \right] \leq -\frac{2c}{N} \sum_{i=1}^N \mathbb{E} \left[ f(E_i^t) \right] + \frac{1}{N} \sum_{i=1}^N \mathbb{E} \left[ \frac{1}{N} \sum_{j=1}^N \Xi_{i,j}^t + \Upsilon_i^t \right] + \omega(\delta) + 2c f(\delta)
\end{equation}

for a.e. $t \geq 0$. By Assumption H2, for all $i, j \in \{1, \ldots, N\}$ and $t \geq 0$,

\begin{equation}
\Xi_{i,j}^t \leq \eta f(E_i^t + E_j^t) \leq \eta \left( f(E_i^t) + f(E_j^t) \right).
\end{equation}

Moreover, in order to control $\Upsilon_i^t$, we remark that given $\bar{X}^{i}_t$, the random variables $\bar{X}^{j}_t$, $j \neq i$, are i.i.d. with law $\bar{\mu}^{i}_t$. In particular,

$$
\mathbb{E} \left[ \nabla W(\bar{X}^{i}_t - \bar{X}^{j}_t) | \bar{X}^{i}_t \right] = \nabla W \ast \bar{\mu}^{i}_t(\bar{X}^{i}_t).
$$

Since by H2, $\nabla W(0) = 0$ and $\nabla W$ is Lipschitz with constant $\eta$, we obtain

$$
\mathbb{E} \left[ \left\| \nabla W \ast \bar{\mu}^{i}_t(\bar{X}^{i}_t) - \frac{1}{N-1} \sum_{j=1}^N \nabla W(\bar{X}^{i}_t - \bar{X}^{j}_t) \right\|^2 \right]^{1/2} \leq \left( \frac{\eta^2}{N-1} \right) \left( \int \|x\|^2 \bar{\mu}^{i}_t(dx) \right)^{1/2}.
$$

Hence, by the Cauchy-Schwarz inequality and (14),

$$
\mathbb{E} \left[ \Upsilon_i^t \right] \leq \mathbb{E} \left[ \left\| \nabla W \ast \bar{\mu}^{i}_t(\bar{X}^{i}_t) - \frac{1}{N-1} \sum_{j=1}^N \nabla W(\bar{X}^{i}_t - \bar{X}^{j}_t) \right\|^2 \right]^{1/2} \leq \eta \left( \frac{1}{N-1} + \frac{\sqrt{2}}{N} \right) \left( \int \|x\|^2 \bar{\mu}^{i}_t(dx) \right)^{1/2}.
$$

By Lemma 8, we conclude that there is an explicit finite constant $C$ such that for $N \geq 2$,

\begin{equation}
\sup_{t \geq 0} \mathbb{E} \left[ \Upsilon_i^t \right] \leq C \eta N^{-1/2}, \quad i = 1, \ldots, N.
\end{equation}
Now, combining (26), (27) and (28), we finally obtain
\[
\frac{d}{dt} \frac{1}{N} \sum_{i=1}^{N} \mathbb{E} \left[ f \left( \| E^i_t \| \right) \right] \leq -2 \frac{c-\eta}{N} \sum_{i=1}^{N} \mathbb{E} \left[ f \left( \| E^i_0 \| \right) \right] + \omega(\delta) + 2cf(\delta) + \frac{C\eta}{\sqrt{N}}
\]
f for a.e. \( t \geq 0 \). Assuming \( \eta < c \), we can conclude that
\[
\frac{1}{N} \sum_{i=1}^{N} \mathbb{E} \left[ f \left( \| E^i_0 \| \right) \right] \leq e^{-2(c-\eta) t} \frac{1}{N} \sum_{i=1}^{N} \mathbb{E} \left[ f \left( \| E^i_0 \| \right) \right] + (2(c-\eta))^{-1} \left( \omega(\delta) + 2cf(\delta) + C\eta N^{-1/2} \right).
\]
Noting that \( \mathbb{E} \left[ f \left( \| E^i_0 \| \right) \right] \leq \int \| x - y \| \, d\xi(x,y) \) for all \( i \in \{1, \ldots, d\} \), we obtain
\[
\mathcal{W}_{\ell^1}(f) \left( \mathcal{L}(X^1_t, \ldots, X^N_t), \bar{\mu}^\nu_t \right) \leq e^{-2(c-\eta) t} \int \| x - y \| \, d\xi(x,y) + (2(c-\eta))^{-1} \left( \omega(\delta) + 2cf(\delta) + C\eta N^{-1/2} \right).
\]
By (23) and H1, \( \lim_{\delta \to 0^+} \omega(\delta) = 0 \). Hence taking the limit as \( \delta \) goes to 0, and the infimum over all couplings \( \xi \in \Pi(\nu, \mu) \) concludes the proof of the second inequality in Theorem 2. The first inequality follows similarly, noting that by (18), for all \( i \in \{1, \ldots, d\} \) and \( t \geq 0 \),
\[
\mathcal{W}_f(\bar{\mu}^\nu_t, \mu^\mu_t) \leq \mathbb{E} \left[ f \left( \| X^i_t - X^i_t \| \right) \right] = \mathbb{E} \left[ f \left( \| E^i_t \| \right) \right].
\]
