Pure Stationary States of Open Quantum Systems

Vasily E. Tarasov
Skobeltsyn Institute of Nuclear Physics, Moscow State University, Moscow 119992, Russia

Using Liouville space and superoperator formalism we consider pure stationary states of open and dissipative quantum systems. We discuss stationary states of open quantum systems, which coincide with stationary states of closed quantum systems. Open quantum systems with pure stationary states of linear oscillator are suggested. We consider stationary states for the Lindblad equation. We discuss bifurcations of pure stationary states for open quantum systems which are quantum analogs of classical dynamical bifurcations.

I. INTRODUCTION

The open quantum systems are of strong theoretical interest. As a rule, any microscopic system is always embedded in some (macroscopic) environment and therefore it is never really closed. Frequently, the relevant environment is in principle unobservable or it is unknown. This would render the theory of open quantum systems a fundamental generalization of quantum mechanics. Classical open and dissipative systems can have regular or strange attractors. Regular attractors can be considered as a set of (stationary) states for closed classical systems correspondent to open systems. Quantization of evolution equations in phase space for dissipative and open classical systems was suggested in Refs. .

This quantization procedure allows one to derive quantum analogs of open classical systems with regular attractors such as nonlinear oscillator and . In the papers we were derived quantum analogs of dissipative systems with strange attractors such as Lorenz-like system, Rossler and Newton-Leipnik systems. It is interesting to consider quantum analogs for regular and strange attractors. The regular "quantum" attractors can be considered as stationary states of open quantum systems. The existence of stationary states for open quantum systems is an interesting fact. The condition given by Davies in Ref. defines the stationary state of open quantum system. An example, where the stationary state is unique and approached by all states for long times is considered by Lindblad for Brownian motion of quantum harmonic oscillator. In Refs. , we derive sufficient condition for the existence of a unique stationary state for the open quantum system described by Lindblad equation . The stationary solution of the Wigner function evolution equation for an open quantum system was discussed in Refs. .

In the steady states of the dissipative map are considered in Ref. .

In this paper we consider stationary pure states of some open quantum systems. These open systems look like closed quantum systems in the pure stationary states. We consider the quantum analog of dynamical bifurcations considered by Thompson and Lunn for classical dynamical systems. In order to describe these systems, we consider Liouville-von Neumann equation for density matrix evolution such that this Liouville generator of the equation is a function of some Hamiltonian operator. Open quantum systems with pure stationary states of linear harmonic oscillator are suggested. We consider the example of bifurcation of pure stationary states for open quantum systems.

In Section II, we introduce pure stationary states for closed quantum systems and some mathematical background is considered. In the Section III, we consider Liouville-von Neumann equation for an open quantum system and pure stationary states for this equation. In Section IV, simple examples stationary states for open quantum systems are considered. In Section V, we study some properties of quantum system to have dynamical bifurcations and catastrophes. In the Section VI, we suggest an example of quantum system with fold catastrophe. Finally, a short conclusion is given in Section VII. In Appendix, the mathematical background (Liouville space, superoperators) is considered.

II. PURE STATIONARY STATE

In the general case, the time evolution of the quantum state \( |\rho_t\rangle \) can be described by the Liouville-von Neumann equation

\[
\frac{d}{dt}|\rho_t\rangle = \hat{\Lambda}|\rho_t\rangle,
\]

where \( \hat{\Lambda} \) is a Liouville superoperator on Liouville space, \( |\rho\rangle \) is a density matrix operator as an element of Liouville space. For the concept of Liouville space and superoperators see the Appendix and Refs. . For closed
systems, Liouville superoperator has the form
\[ \dot{\Lambda} = -\frac{i}{\hbar}(\hat{L}_H - \hat{R}_H) \quad \text{or} \quad \dot{\Lambda} = \hat{L}_H, \] (2)
where \( H = H(q, p) \) is a Hamilton operator. If the Liouville superoperator \( \hat{\Lambda} \) cannot be represented in the form \( \hat{\Lambda} = \hat{L}_H \), then quantum system is called open, non-Hamiltonian or dissipative quantum system \( [36, 37, 38] \).

The stationary state is defined by the following condition:
\[ \hat{\Lambda}(\rho_t) = 0. \] (3)
For closed quantum systems \( [2] \), this condition has the simple form:
\[ \hat{L}_H|\rho_t\rangle = \hat{R}_H|\rho_t\rangle \quad \text{or} \quad \hat{L}_H^+|\rho_t\rangle = 0. \] (4)

In the general case, we can consider the Liouville superoperator as a superoperator function \( [7, 8, 36] \):
\[ \hat{\Lambda} = \Lambda(\hat{L}_X, \hat{R}_X), \]
where \( X \) is a set of linear operators. For example, \( X = \{q, p, \hat{H}\} \) or \( X = \{H_1, ..., H_s\} \). In the paper we use the special form of the superoperator \( \hat{\Lambda} \) such that
\[ \dot{\Lambda} = -\frac{i}{\hbar}(\hat{L}_H - \hat{R}_H) + \sum_{k=1}^{s} \hat{F}_k N_k(\hat{L}_H, \hat{R}_H), \]
where \( N_k(\hat{L}_H, \hat{R}_H) \) are some superoperator functions and \( \hat{F}_k \) is an arbitrary nonzero superoperator.

It is known that a pure state \( |\rho_\Phi\rangle \) is a stationary state of a closed quantum system \( [1, 2] \), if the state \( |\rho_\Phi\rangle \) is an eigenvector of the Liouville space for superoperators \( \hat{L}_H \) and \( \hat{R}_H \):
\[ \hat{L}_H|\rho_\Phi\rangle = |\rho_\Phi\rangle E, \quad \hat{R}_H|\rho_\Phi\rangle = |\rho_\Phi\rangle E. \] (5)
Equivalently, the state \( |\rho_\Phi\rangle \) is an eigenvector of superoperators \( \hat{L}_H^+ \) and \( \hat{L}_H^- \) such that
\[ \hat{L}_H^+|\rho_\Phi\rangle = |\rho_\Phi\rangle E, \quad \hat{L}_H^-|\rho_\Phi\rangle = |\rho_\Phi\rangle E = 0. \]
The energy variable \( E \) can be defined by
\[ E = (I|\hat{L}_H|\rho_\Phi\rangle = (I|\hat{L}_H^+|\rho_\Phi\rangle. \]
The superoperators \( \hat{L}_H \) and \( \hat{R}_H \) for linear harmonic oscillator are
\[ \hat{L}_H = \frac{1}{2m} \hat{L}_p^2 + \frac{m\omega^2}{2} \hat{L}_q^2, \quad \hat{R}_H = \frac{1}{2m} \hat{R}_p^2 + \frac{m\omega^2}{2} \hat{R}_q^2. \] (6)
It is known that pure stationary states \( \rho_\Phi^s = \rho_{\Phi_1}^s \) of linear harmonic oscillator \( [9] \) exists if the variable \( E \) is equal to
\[ E_n = \frac{1}{2} \hbar \omega (2n + 1). \] (7)

### III. Pure Stationary States of Open Systems

Let us consider the Liouville-von Neumann equation \( [1] \) for the open quantum system defined of the form
\[ \frac{d}{dt}|\rho_t\rangle = -\frac{i}{\hbar}(\hat{L}_H - \hat{R}_H)|\rho_t\rangle + \sum_{k=1}^{s} \hat{F}_k N_k(\hat{L}_H, \hat{R}_H)|\rho_t\rangle. \] (8)
Here \( \hat{F}_k \) is some superoperator and \( N_k(\hat{L}_H, \hat{R}_H) \), where \( k = 1, ..., s \), are superoperator functions.

Let \( |\rho_\Phi\rangle \) is a pure stationary state of the closed quantum system defined by Hamilton operator \( H \). If Eqs. \( [5] \) are satisfied, then the state \( |\rho_\Phi\rangle \) is a stationary state of the closed system associated with the open system \( [\theta] \) and is defined by
\[ \frac{d}{dt}|\rho_t\rangle = -\frac{i}{\hbar}(\hat{L}_H - \hat{R}_H)|\rho_t\rangle. \] (9)

If the vector \( |\rho_\Phi\rangle \) is an eigenvector of operators \( \hat{L}_H \) and \( \hat{R}_H \), then the Liouville-von Neumann equation \( [\theta] \) for the pure state \( |\rho_\Phi\rangle \) has the form
\[ \frac{d}{dt}|\rho_\Phi\rangle = \sum_{k=1}^{s} \hat{F}_k |\rho_\Phi\rangle N_k(E, E), \]
where the function \( N_k(E, E) \) are defined by
\[ N_k(E, E) = (I|\hat{L}_H, \hat{R}_H|\rho_\Phi\rangle. \]
If all functions \( N_k(E, E) \) are equal to zero
\[ N_k(E, E) = 0, \] (10)
then the stationary state \( |\rho_\Phi\rangle \) of the closed quantum system \( [\theta] \) is the stationary state of the open quantum system \( [\theta] \).

Note that functions \( N_k(E, E) \) are eigenvalues and \( |\rho_\Phi\rangle \) is the eigenvector of superoperators \( N_k(\hat{L}_H, \hat{R}_H) \), since
\[ N_k(\hat{L}_H, \hat{R}_H)|\rho_\Phi\rangle = |\rho_\Phi\rangle N_k(E, E). \]
Therefore stationary states of the open quantum system \( [\theta] \) are defined by zero eigenvalues of superoperators \( N_k(\hat{L}_H, \hat{R}_H) \).

### IV. Open Systems with Oscillator Stationary States

In this section simple examples of open quantum systems \( [\theta] \) are considered.

1) Let us consider the nonlinear oscillator with friction defined by the equation
\[ \frac{d}{dt}|\rho_t\rangle = -\frac{i}{\hbar}(\hat{H}, |\rho_t\rangle) - \frac{i}{2\hbar} \beta [q^2|\rho_t|^2 + p^2|\rho_t|^2], \] (11)
where the operator $\hat{H}$ is the Hamilton operator of the nonlinear oscillator:

$$\hat{H} = \frac{p^2}{2m} + \frac{m\Omega^2 q^2}{2} + \frac{\gamma q^4}{2}.$$  

Equation (11) can be rewritten in the form

$$\frac{d}{dt} \rho_t = \hat{L}_H \rho_t +$$

$$+ 2m\beta \hat{L}_q^2 \left( \frac{1}{2m} (\hat{L}_q^2)^2 + \frac{\gamma}{2m\beta} (\hat{L}_q^2)^2 - \frac{\Delta}{4\beta} \hat{L}_I \right) \rho_t,$$

(12)

where $\Delta = \Omega^2 - \omega^2$ and the superoperator $\hat{L}_H$ is defined for the Hamilton operator $H$ of the linear harmonic oscillator by Eqs. (2) and (6). Equation (12) has the form 8, with

$$N(\hat{L}_H, \hat{R}_H) = \frac{1}{2} (\hat{L}_H + \hat{R}_H) - \frac{\Delta}{2\beta} \hat{L}_I,$$

where $\Delta = \Omega^2 - \omega^2$ and the superoperator $\hat{L}_H$ is defined by formulas 7 and 6. Equation (12) has the form 8, if the superoperators $\hat{F}$ and $N(\hat{L}_H, \hat{R}_H)$ are defined by

$$\hat{F} = -\frac{i}{\hbar} (\hat{L}_q - \hat{R}_q),$$

$$N(\hat{L}_H, \hat{R}_H) = \cos \left( \frac{\pi}{\varepsilon_0} (\hat{L}_H + \hat{R}_H) \right) =$$

$$= \sum_{m=0}^{\infty} \frac{1}{(2m)!} \left( \frac{i\pi}{\varepsilon_0} \right)^{2m} (\hat{L}_H + \hat{R}_H)^{2m}.\quad (14)$$

The function $N(E, E)$ has the form

$$N(E, E) = \cos \left( \frac{\pi E}{\varepsilon_0} \right) = \sum_{m=0}^{\infty} \frac{1}{(2m)!} \left( \frac{i\pi E}{\varepsilon_0} \right)^{2m}.$$

The stationary state condition (10) has the solution

$$E = \frac{\varepsilon_0}{2} (2n + 1),$$

where $n$ is an integer number. If parameter $\varepsilon_0$ is equal to $\hbar\omega$, then quantum system 13 and 14 has pure stationary states of the linear harmonic oscillator with the energy 7. As the result, stationary states of the open quantum system 13 coincide with pure stationary states of linear harmonic oscillator. If the parameter $\varepsilon_0$ is equal to $\hbar\omega(2m + 1)$, then quantum system 13 and 14 have stationary states of the linear harmonic oscillator with $n(k, m) = 2km + k + m$ and

$$E_{n(k, m)} = \frac{\hbar\omega}{2} (2k + 1)(2m + 1).$$

3) Let us consider the superoperator function $N_k(\hat{L}_H, \hat{R}_H)$ in the form

$$N_k(\hat{L}_H, \hat{R}_H) = \frac{1}{2\hbar} \sum_{n, m} v_{kn} v_{km}^\ast \left( 2\hat{L}_H \hat{R}_H - \hat{L}_H \hat{R}_H \right),$$

and all superoperators $\hat{F}_k$ are equal to $\hat{L}_I$. In this case, the Liouville-von Neumann equation 5 can be represented by the Lindblad equation 33 34 35:

$$\frac{d}{dt} \rho_t = -i \hbar (\hat{L}_H - \hat{R}_H) \rho_t +$$

$$+ \frac{1}{2\hbar} \sum_j \left( 2\hat{L}_{V_j} \hat{R}_{V_j}^\ast - \hat{L}_{V_j} \hat{R}_{V_j}^\ast \right) \rho_t,$$

(15)

with linear operators $V_k$ defined by

$$V_k = \sum_n v_{kn} H^n, \quad V_k^\dagger = \sum_m v_{km}^\ast H^m.\quad (16)$$

If $\rho_k$ is a pure stationary state 5, then all functions $N_k(E, E)$ are equal to zero and this state $\rho_k$ is a stationary state of the open quantum system 13.

If the Hamilton operator $H$ is defined by

$$H = \frac{1}{2m} p^2 + \frac{m\omega^2}{2} q^2 + \frac{\lambda}{2} (qp + pq),$$

then we have some generalization of the quantum model for the Brownian motion of a harmonic oscillator considered in 11. Note that in the model 11 operators $V_k$ are linear $V_k = a_k p + b_k q$, but in our generalization 13 and 16 these operators are nonlinear. For example, we can use

$$V_k = a_k p + b_k q + c_k p^2 + d_k q^2 + e_k (qp + pq).$$

The case $c_k = d_k = e_k = 0$ is considered in Ref. 11. Let real parameters $\alpha$ and $\beta$ exist and

$$b_k = \alpha a_k, \quad c_k = \beta a_k, \quad d_k = m^2 \omega^2 \beta a_k, \quad e_k = m \lambda a_k.$$  

In this case, the pure stationary states of the linear oscillator 17 exist if $\omega > \lambda$ and the variable $E$ is equal to

$$E_n = \frac{1}{2} \hbar\omega(2n + 1) \sqrt{1 - \lambda^2/\omega^2}.$$
V. DYNAMICAL BIFURCATIONS AND CATASTROPHES

Let us consider a special case of open quantum systems $S$ such that the vector function

$$N_k(E, E) = (I|N_k(\hat{L}_H, \hat{R}_H)|\rho),$$

be a potential function and the Hamilton operator $H$ can be represented in the form

$$H = \sum_{k=1}^{s} H_k.$$  

In this case we have a function $V(E)$ called potential, such that the following conditions are satisfied:

$$\frac{\partial V(E)}{\partial E_k} = N_k(E, E),$$

where $E_k = (I|\hat{L}_H|\rho) = (I|\hat{R}_H|\rho)$. If potential $V(E)$ exists, then the stationary state condition (10) for the open quantum system $[S]$ is defined by critical points of the potential $V(E)$. If the system has one variable $E$, then the potential $V(E, E)$ is a potential function. In general, the vector function $N_k(E, E)$ is potential, if

$$\frac{\partial N_k(E, E)}{\partial E_k} = \frac{\partial N_k(E, E)}{\partial E_k}.$$  

Stationary states of the open quantum system $S$ with potential vector function $N_k(E, E)$ depend on a critical points of the potential $V(E)$. It allows one to use the theory of bifurcations and catastrophes for the parametric set of functions $V(E)$. Note that a bifurcation in a vector space of variables $E = \{E_k|k = 1, ..., s\}$ is a bifurcation in the vector space of eigenvalues of the Hamilton operator $H_k$.

For the polynomial superoperator function $N_k(\hat{L}_H, \hat{R}_H)$ we have

$$N_k(\hat{L}_H, \hat{R}_H) = \sum_{n=0}^{N} \sum_{m=0}^{n} a_n^{(k)} m! \hat{R}^{n-m}.$$  

In general case, $m$ and $n$ are multi-indices. The function $N_k(E, E)$ is a polynomial

$$N_k(E, E) = \sum_{n=0}^{N} \alpha_n^{(k)} E^n,$$

where the coefficients $\alpha_n^{(k)}$ are defined by

$$\alpha_n^{(k)} = \sum_{m=0}^{n} a_n^{(k)} m!.$$  

We can define the variables $x_l = E_l - a_l$ $(l = 1, ..., s)$, such that functions $N_k(E, E) = N_k(x + a, x + a)$ have no the terms $x_l^{n-1}$.

$$N_k(x + a, x + a) = \sum_{n=0}^{N} \alpha_n^{(k)} (x + a)^n = \sum_{n=0}^{N} \frac{n!}{m!(n-m)!} x^{n-m} \alpha_n^{(k)} (k)^{n-m}.$$  

If the coefficient of the term $x_l^{n-1}$ is equal to zero

$$a_{n_l}^{(k)} \frac{n_l!}{(n_l - 1)!} \alpha_{n_l}^{(k)} + \alpha_{n_l - 1}^{(k)} = \alpha_{n_l}^{(k)} \frac{n_l!}{n_l (n_l - 1)!} \alpha_{n_l}^{(k)} + \alpha_{n_l - 1}^{(k)} = 0,$$

then we have the following coefficients

$$\alpha_0^{(k)} = -\frac{\alpha_{n_l - 1}^{(k)}}{n_l \alpha_{n_l}^{(k)}}.$$  

If we change parameters $\alpha_n^{(k)}$, then an open quantum system can have pure stationary states of the system. For example, the bifurcation with the birth of linear oscillator pure stationary state is a quantum analog of dynamical Hopf bifurcation [10, 11] for classical dynamical system.

Let a vector space of energy variables $E$ be a one-dimensional space. If the function $N(E, E)$ is equal to

$$N(E, E) = \pm \alpha_n E^n + \sum_{j=1}^{n-1} \alpha_j E^j n \geq 2,$$

then the potential $V(x)$ is defined by the following equation:

$$V(x) = \pm x^{n+1} + \sum_{j=1}^{n-1} \alpha_j x^j n \geq 2,$$

and we have catastrophe of type $A_{\pm n}$.

If we have $s$ variables $E_l$, where $l = 1, 2, ..., s$, then quantum analogs of elementary catastrophes $A_{\pm n}$, $D_{\pm n}$, $E_{\pm 6}$, $E_7$ and $E_8$ can be realized for open quantum systems. Let us write the full list of potentials $V(x)$, which leads to elementary catastrophes (zero modal) defined by $V(x) = V_0(x) + Q(x)$, where

$$A_{\pm n} : V_0(x) = \pm x_1^{n+1} + \sum_{j=1}^{n-1} x_1^j x_1^j n \geq 2,$$

$$D_{\pm n} : V_0(x) = x_1^2 x_2 \pm x_2^{n-1} + \sum_{j=1}^{n-3} x_1^j x_1^{n-3},$$

$$E_{\pm 6} : V_0(x) = (x_1^3 \pm x_2^3) + \sum_{j=1}^{2} a_j x_2^j + \sum_{j=3}^{5} a_j x_1 x_2^j,$$

$$E_7 : V_0(x) = x_1^3 + x_1 x_2^3 + \sum_{j=1}^{4} a_j x_2^j + \sum_{j=5}^{6} a_j x_1 x_2^{j-5},$$

$$E_8 : V_0(x) = x_1^3 + x_1^5 + \sum_{j=1}^{3} a_j x_2^j + \sum_{j=4}^{7} a_j x_1 x_2^{j-4}.$$  

Here $Q(x)$ is the nondegenerate quadratic form with variables $x_2, x_3, ..., x_s$ for $A_{\pm n}$ and parameters $x_3, ..., x_s$ for other cases.
VI. FOLD CATASTROPHE

In this section, we suggest an example of the open quantum system with catastrophe $A_2$ called fold.

Let us consider the Liouville-von Neumann equation \( \hat{F} \) for a nonlinear quantum oscillator with friction, where multiplication superoperators $\hat{L}_H$ and $\hat{R}_H$ are defined by Eq. (8) and superoperators $\hat{N}$ and $\hat{R}(\hat{L}_H, \hat{R}_H)$ are given by the following equations:

$$
\hat{F} = -2\hat{L}_q \hat{L}_p^+, 
$$
(18)

$$
\hat{N}(\hat{L}_H, \hat{R}_H) = \alpha_0 \hat{L}_q^+ + \alpha_1 \hat{L}_q^+ \hat{L}_q^+ + \alpha_2 (\hat{L}_q^+)^2,
$$
(19)

In this case, the function $N(E, E)$ is equal to

$$
N(E, E) = \alpha_0 + \alpha_1 E + \alpha_2 E^2.
$$

A pure stationary state $|\rho_0\rangle$ of the linear harmonic oscillator is a stationary state of the open quantum system \([13]\), if $N(E, E) = 0$. Let us define the new real variable $x$ and parameter $\lambda$ by the following equation

$$
x = E + \frac{\alpha_1}{2\alpha_2}, \quad \lambda = \frac{4\alpha_0\alpha_2 - \alpha_1^2}{4\alpha_2^2}.
$$

Then we have the stationary condition $N(E, E) = 0$ in the form $x^2 - \lambda = 0$. If $\lambda \leq 0$, then the open quantum system has no stationary states. If $\lambda > 0$, then we have pure stationary states for a discrete set of parameter values $\lambda$. If the parameters $\alpha_1, \alpha_2$ and $\lambda$ satisfy the following conditions

$$
-\frac{\alpha_1}{2\alpha_2} = \hbar\omega(n + \frac{1}{2} + \frac{m}{2}), \quad \lambda = \hbar^2 \omega^2 \frac{m^2}{4},
$$
where $n$ and $m$ are non-negative integer numbers, then the open quantum system \([13]\) and \([16]\) has two pure stationary state of the linear harmonic oscillator. The energies of these states are equal to

$$
E_n = \hbar\omega(n + \frac{1}{2}), \quad E_{n+m} = \hbar\omega(n + m + \frac{1}{2}).
$$

VII. CONCLUSION

Open quantum systems with two stationary states can be considered as qubit. It allows one to consider open n-qubit quantum system described by Eq. (8) as a quantum computer with pure states. In general, we can consider open n-qubit quantum systems as quantum computer with mixed states \([14, 16]\). A mixed state (operator of density matrix) of n two-level quantum systems (open or closed n-qubit system) is an element of $4^n$-dimensional operator Hilbert space (Liouville space). It allows one to use quantum computer model with four-valued logic \([14, 16]\). The quantum gates of this model are real, completely positive, trace-preserving superoperators that act on mixed state. Bifurcations of pure quantum states can used for quantum gate control.

This work was partially supported by the RFBR Grant No. 02-02-16444.

Appendix

For the concept of Liouville space and superoperators see Refs. \([20-37]\).

Liouville space

The space of linear operators acting on a Hilbert space $\mathcal{H}$ is a complex linear space $\mathcal{H}$. We denote an element $A$ of $\mathcal{H}$ by a ket-vector $|A\rangle$. The inner product of two elements $|A\rangle$ and $|B\rangle$ of $\mathcal{H}$ is defined as $\langle A|B \rangle = Tr(A^\dagger B)$. The norm $||A|| = \sqrt{\langle A|A \rangle}$ is the Hilbert-Schmidt norm of operator $A$. A new Hilbert space $\mathcal{H} \oplus \mathcal{H}$ with the inner product is called Liouville space attached to $\mathcal{H}$ or the associated Hilbert space, or Hilbert-Schmidt space $\mathcal{H}$.

Let $\{ |x \rangle \}$ be an orthonormal basis of $\mathcal{H}$:

$$
<x|x'> = \delta(x-x') , \quad \int dx|x><x| = I.
$$

Then $|x,x'\rangle = |x><x'|$ is an orthonormal basis of the Liouville space $\mathcal{H}$:

$$
(x,x'|y,y') = \delta(x-x')\delta(y-y'),
$$
$$
\int dx\int dx'|x,x')(x,x'| = I. \quad (20)
$$

For an arbitrary element $|A\rangle$ of $\mathcal{H}$, we have

$$
|A\rangle = \int dx\int dx'|x,x')(x,x'|A) \quad (21)
$$

where

$$
(x,x'|A) = Tr(|x><x'|A).$$

Open quantum systems with two stationary states can be considered as qubit. It allows one to consider open n-qubit quantum system described by Eq. (8) as a quantum computer with pure states. In general, we can consider open n-qubit quantum systems as quantum computer with mixed states \([14, 16]\). A mixed state (operator of density matrix) of n two-level quantum systems (open or closed n-qubit system) is an element of $4^n$-dimensional operator Hilbert space (Liouville space). It allows one to use quantum computer model with four-valued logic \([14, 16]\). The quantum gates of this model are real, completely positive, trace-preserving superoperators that act on mixed state. Bifurcations of pure quantum states can used for quantum gate control.
is a kernel of the operator $A$. An operator $\rho$ of density matrix ($Tr\rho = 1$, $\rho^\dagger = \rho$, $\rho \geq 0$) can be considered as an element $|\rho\rangle$ of the Liouville space $\mathcal{H}$. Using (21), we get

$$|\rho\rangle = \int dx \int dx'|x, x')(x, x'|\rho), \quad (22)$$

where the trace is represented by

$$(I|\rho) = Tr\rho = \int dx \langle x|x|\rho\rangle = 1.$$

### Superoperators

Operators that act on $\mathcal{H}$ are called superoperators and we denote them, in general, by the hat.

For an arbitrary superoperator $\hat{\Lambda}$ on $\mathcal{H}$, which is defined by

$$\hat{\Lambda}|A\rangle = |\hat{\Lambda}(A)\rangle,$$

we have

$$(x, x'|\hat{\Lambda}|A\rangle) = \int dy \int dy' \langle x, y'|\hat{\Lambda}|y, y'\rangle\langle y, y'|A\rangle =$$

$$= \int dy \int dy' \Lambda(x, x', y, y')A(y, y'),$$

where $\Lambda(x, x', y, y')$ is a kernel of the superoperator $\hat{\Lambda}$.

Let $A$ be a linear operator in the Hilbert space $\mathcal{H}$. We can define the multiplication superoperators $\hat{L}_A$ and $\hat{R}_A$ by the following equations

$$\hat{L}_A|B\rangle = |AB\rangle, \quad \hat{R}_A|B\rangle = |BA\rangle.$$

The superoperator kernels can be easy derived. For example, in the basis $|x, x'\rangle$ we have

$$(x, x'|\hat{L}_A|B\rangle) = \int dy \int dy' \langle x, x'|\hat{L}_A|y, y'\rangle\langle y, y'|B\rangle =$$

$$= \int dy \int dy' L_A(x, x', y, y')B(y, y').$$

Using

$$(x, x'|AB\rangle) = \langle x|AB|x'\rangle =$$

$$= \int dy \int dy' < x|A|y > < y|B|y' > < y'|x' >,$$

we get kernel of the left multiplication superoperator

$$(\hat{L}_A)(x, x', y, y') = < x|A|y > < x'|y' > = A(x, y)\delta(x' - y').$$

Left superoperators $\hat{L}_A^\pm$ are defined as Lie and Jordan multiplication by

$$\hat{L}_A^-B = \frac{1}{i\hbar}(AB - BA), \quad \hat{L}_A^+B = \frac{1}{2}(AB + BA).$$

The left superoperators $\hat{L}_A^\pm$ and right superoperators $\hat{R}_A^\pm$ are connected by

$$\hat{L}_A^- = -\hat{R}_A^-, \quad \hat{L}_A^+ = \hat{R}_A^+.$$

An algebra of the superoperators $\hat{L}_A^\pm$ is defined by the following relations

1) Lie relations

$$\hat{L}_A^-B = \hat{L}_A^-\hat{L}_B - \hat{L}_B\hat{L}_A^-.$$

2) Jordan relations

$$\hat{L}_A^+(AB)c + \hat{L}_B^c\hat{L}_A^+ + \hat{L}_A^+\hat{L}_C\hat{L}_B^+ =$$

$$= \hat{L}_A^+B\hat{L}_C + \hat{L}_B\hat{L}_A^+ + \hat{L}_A\hat{L}_C\hat{L}_B^+,$$

$$\hat{L}_{(AB)c}^+L_A^+ = \hat{L}_{L_B}^c\hat{L}_A^+ + \hat{L}_A\hat{L}_C\hat{L}_B^+ =$$

$$= \hat{L}_C^+\hat{L}_A^+\hat{L}_B^+ + \hat{L}_B\hat{L}_A^+\hat{L}_C + \hat{L}_A^+\hat{L}_B^+\hat{L}_C.$$

3) Mixed relations

$$\hat{L}_A^+L_B^+ = \hat{L}_A^+L_B^+ - \hat{L}_B^+L_A^-,$$

$$\hat{L}_A^+ = \hat{L}_A^+L_B^+ + \hat{L}_B\hat{L}_A^-, \quad \hat{L}_A^+ = \hat{L}_A^+L_B^+ - \frac{\hbar^2}{4}\hat{L}_B\hat{L}_A^-,$$

$$\hat{L}_B\hat{L}_A^+ - \hat{L}_A^+\hat{L}_B^+ = -\frac{\hbar^2}{4}\hat{L}_A^-\hat{L}_B^+,$$

where

$$A \cdot B = \frac{1}{i\hbar}(AB - BA), \quad A \circ B = \frac{1}{2}(AB + BA).$$
