Abstract

We present fits to determine Parton Distribution Functions using a diverse set of measurements from the ATLAS experiment at the LHC, including inclusive \(W\) and \(Z\) boson production, \(t\bar{t}\) production, \(W\)-jets and \(Z\)-jets production, inclusive jet production and direct photon production. These ATLAS measurements are used in combination with deep-inelastic scattering data from the electron-proton collider HERA. Particular attention is paid to the correlation of systematic uncertainties within and between the various ATLAS data sets and to the impact of model, theoretical and parameterisation uncertainties.

1 Introduction and input data sets

Parton Distribution Functions (PDFs) represent one of the main sources of theoretical systematic uncertainties in hadronic collisions. A precise knowledge of PDFs is a necessary ingredient for accurate predictions of Standard Model (SM). Furthermore, they influence the potential of experimental searches for discovering or setting exclusion bounds in many Beyond the Standard Model (BSM) scenarios.

In this proceeding, a review of the most recent determination of PDFs by the ATLAS Collaboration [1] is presented. This fit represents the first comprehensive and comparative quantum chromodynamics (QCD) analysis of a number of ATLAS data sets with potential sensitivity to PDFs. The data sets in use are described in the following: the high precision measurements of the inclusive differential \(W^\pm\) and \(Z/\gamma^*\) boson cross sections at 7 TeV [2], differential \(t\bar{t}\) distributions in the lepton + jets and dilepton channels at 8 TeV [3], data on the production of \(W\) and \(Z\) bosons in association with jets \((V + \text{jets})\) [4, 5], the data on \(W\) [6] production and \(Z/\gamma^*\) [7] production with 20.2 fb\(^{-1}\) at 7 TeV, the direct photon production differential cross sections with 20.2 fb\(^{-1}\) at 8 TeV and 3.2 fb\(^{-1}\) at 13 TeV are added in the form of their ratios [8], the \(t\bar{t}\) differential cross sections in the lepton + jets channel from 3.2 fb\(^{-1}\) at 13 TeV [9] and inclusive jet production cross sections with 4.5 fb\(^{-1}\) at 7 TeV [10], 20.2 fb\(^{-1}\) at 8 TeV [11] and 3.2 fb\(^{-1}\) at 13 TeV [12]. All these analyses use \(pp\) collisions data collected with the ATLAS detector [13] at the Large Hadron Collider (LHC). The ATLAS data sets are added on top of the combined \(e^\pm p\) cross-section measurements of H1 and ZEUS [14]. These HERA data are the backbone of modern QCD analyses because they cover a kinematic range of \(Q^2\) from 4.5 \cdot 10^{-2}\ GeV\(^2\) to 5 \cdot 10^4\ GeV\(^2\) and for Bjorken-x from 6 \cdot 10^{-7} to 0.65 (Neutral Current - NC) and Q2 \sim 300\ GeV\(^2\) to beyond 10^4\ GeV\(^2\) and of x from \sim 0.65 down to \sim 10^{-2} (Charged Current - CC).

2 Theoretical framework and fit methodology

The \texttt{xFitter} framework [15, 16, 17] has been interfaced to theoretical calculations directly or uses fast interpolation grids to make theoretical predictions for the considered processes. The predictions for all the processes are calculated to next-to-next-to-leading order (NNLO) in QCD and next-to-leading order (NLO) in electroweak (EW) theory. PDFs are parametrised as a function of \(x\) at a starting scale \(Q_0^2 = 1.9\ GeV^2\). The values of the heavy-quark masses are \(m_c = 1.41\ GeV\) and \(m_b = 4.2\ GeV\) respectively, as suggested in a recent re-analysis of the HERA heavy-quark data [19].

3 Inclusion of correlations between data sets

In Ref. [1], the correlation of systematic uncertainties within each data set and between data sets has been carefully investigated. The differences between the extracted PDFs with and without inter-data-set correlations are mostly in the $d$-type sector and can reach $\sim 20\%$ for $xd$ at large $x$, as illustrated in Figure 1 at scale relevant for precision LHC physics, namely $Q^2 = 10^4$ GeV$^2$. Although these differences are not large compared to current experimental precision, they can nevertheless be important if the desired accuracy of the PDFs is $O(1\%)$, as stated in a recent NNPDF study [20].

4 Inclusion of scale uncertainties

Only for the data sets where the precision of the measurements is comparable to the size of the NNLO scale uncertainties, we considered the inclusion of these uncertainties as additional theoretical uncertainties. These data sets are the ATLAS $W$ and $Z/\gamma^*$ inclusive ones at both 7 and 8 TeV. Due to the similarity of the $W$ and $Z$ processes, both the factorisation ($\mu_F$) and renormalisation ($\mu_R$) scales are treated as correlated between these two data set. Furthermore, alternative scenarios where scale uncertainties are included but not correlated between 7 and 8 TeV data sets or where they are not applied at all are considered as well. Figure 2 shows the results of the two above-mentioned cases, compared with the central fit, at a scale $Q^2 = 10^4$ GeV$^2$. The differences between the shapes of the PDFs are not large, but they can be important for precise PDF determination. The size of the PDF uncertainties is very similar, whether or not the scale uncertainties are included. For the other processes the experimental uncertainties are larger than the scale uncertainties and in this case these uncertainties are treated by repeating the fit with varied scales.

5 Impact of the various data sets on PDFs

Figure 3 shows the $R_s = x(s + \bar{s})/x(\bar{u} + \bar{d})$ for the ATLASpdf21 fit compared with a fit without the inclusion of $W$, $Z$ data at 7 and 8 TeV. This ratio cannot be determined reliably without $W$, $Z$ inclusive data. Adding the $V + jets$ data at 8 TeV changes the $xd$ and $x\bar{s}$ PDF shapes at high $x$ and resolves a double minimum in parameter space such that a harder $xd$ and a softer $x\bar{s}$ are now preferred at high $x$ (a similar result has been already discussed in the ATLASepWZVjets20 PDF fit [21]). $t\bar{t}$ data soften the $xg$ PDF at high $x$ and reduce the uncertainties for $x > 0.1$ by $\sim 20\%$, as shown in Figure 3. The principal impact of the inclusive jet data is on the gluon PDF. They prefer a mildly harder gluon at high $x$, as shown in Figure 3 and the addition of this specific data set decreases the PDF uncertainties for $x > 0.2$ considerably.
Figure 2: ATLASpdf21, showing the ratios of a fit not including theoretical scale uncertainties in the inclusive $W$, $Z$ data to the central fit which does include these uncertainties, at the scale $Q^2 = 10^{4}$ GeV$^2$. Experimental uncertainties are shown, evaluated with tolerance $T = 1$. Left: $x \bar{d}V$. Right: $x d$. These plots are taken from Ref. [1].

6 Enhanced tolerance and comparison with modern PDF fits

To take into account possible inconsistencies between the independent fitted data sets and unknown experimental and theoretical uncertainties, following the dynamic tolerance procedure introduced in the MSTW paper [22], a tolerance of $T = 3$ is found to be a reasonable choice and is applied for the final estimation of PDF uncertainty. The ATLASpdf21 PDFs evaluated with full uncertainties are compared to HERAPDF2.0 [14], CT18 [23] and CT18A [23] in Figure 4. Looking at the $x \bar{d}V$ and $x d$ distributions, it is clear that the ATLASpdf21 PDFs get closer to global fits, as soon as more LHC data sets are included. It is very nice to notice that the $x \bar{s}$ distribution is in good agreement with CT18A (the only fit which includes the ATLAS $W$ and $Z/\gamma^*$ data at 7 TeV). Finally, the gluon distribution agrees best with HERAPDF2.0, but is in a reasonable agreement with the other global PDFs. The ATLASpdf21 fit exhibits a $\chi^2$/NDF of 2010/1620, while, for the considered global fits, the $\chi^2$ values for the data sets included in the ATLASpdf21 fit are HERAPDF2.0: 2262, CT18: 2135 and CT18A: 2133. Interestingly, the $\chi^2$ value of the ATLASpdf21 fit is better for the considered data sets, although the global PDFs from CT have more flexible parametrisation.

7 Conclusion

In this proceeding, we presented the ATLASpdf21 fit, the first one by an experimental collaboration at the LHC which uses an enhanced tolerance for the computation of experimental PDF uncertainties. Furthermore, the role of scale uncertainties has been considered and these additional theoretical uncertainties have been implemented where they are most impactful. Moreover, correlation of systematic uncertainties within and between ATLAS data sets are considered. The effects of these correlations, as well as the inclusion of scale uncertainties, are relatively small a scale relevant for precision physics at the LHC, but large enough to be considered in future measurements of SM parameters and searches for BSM physics.
