Abstract

In this work, a two dimensional problem in magnetic micropolar generalized thermoelastic medium, in the presence of a transverse magnetic field -taking into consideration the effect of Hall current- subjected to ramp-type heating, is investigated. The entire elastic medium is rotating with a uniform angular velocity. Laplace-Fourier transform technique is used to solve the problem. The transformed components of normal strain, normal stress, tangential couple stress, temperature distribution, and the current density components are obtained. The integral transforms have been inverted by using a numerical technique. Hall current effects and effect of rotation have been depicted graphically on the resulting quantities.

Keywords

Hall Current, Micropolar, Thermoelasticity, Ramp-Type Heating

1. Introduction

The linear theory of elasticity is of paramount importance in the stress analysis of steel, which is the commonest engineering structural material. To a lesser extent, linear elasticity describes the mechanical behavior of the other common solid materials, e.g. concrete, wood and coal. However, the theory does not apply to the behavior of many of the new synthetic materials of the elastomer and polymer type, e.g. polymethyl-methacrylate (Perspex), polyethylene and polyvinyl chloride. The linear theory of micropolar elasticity is adequate to represent the behavior of such materials. For ultrasonic waves i.e. for the case of elastic vibrations characterized by high frequencies and small wavelengths, the influence of the body microstructure becomes significant. This influence of microstructure results in the development of new type of waves, not found in the classical theory of elasticity. Metals, polymers, composites, soils, rocks, concrete are typical media with microstructures. More generally, most of the natural and manmade materials including engineering, geological and biological media possess a microstructure. Eringen and Suhubi[1] and Suhubi and Eringen[2] developed the nonlinear theory of micro-elastic solids. Later Eringen[3-5] developed a theory for the special class of micro-elastic materials and called it the “linear theory of micropolar elasticity”. Under this theory, solids can undergo macro-deformations and macro-rotations.

The classical uncoupled theory of thermoelasticity predicts two phenomena not compatible with physical observations. First, the equation of heat conduction of this theory does not contain any elastic terms, second, the heat equation is of a parabolic type, predicting infinite speeds of propagation for heat waves.

Biot[6] introduced the theory of coupled thermoelasticity to overcome the first shortcoming. The governing equations for this theory are coupled, eliminating the first paradox of the classical theory. However, both theories share the second shortcoming since the heat equation for the coupled theory is also parabolic.

Two generalizations to the coupled theory were introduced. The first is due to Lord and Shulman[7], who obtained a wave-type heat equation by postulating a new law of heat conduction to replace the classical Fourier’s law. Since the heat equation of this theory is of the wave-type, it automatically ensures finite speeds of propagation for heat and elastic waves. The remaining governing equations for this theory, namely, the equations of motion and constitutive relations, remain the same as those for the coupled and the uncoupled theories. The second generalization is known as the theory of thermoelasticity with two relaxation times, or the theory of temperature-rate-dependent thermoelasticity, and was proposed by Green and Lindsay[8]. It is based on a form of the entropy inequality proposed by Green and Laws[9]. It does not violate Fourier’s law of heat conduction when the body under consideration has a center of symmetry, and it is valid for both isotropic and anisotropic
bodies. Ezzat and Youssef[10] studied the generalized magneto-thermoelasticity in a perfectly conducting medium.

The foundations of magnetoelasticity were presented by Knopoff[11] and Chadwick[12] and developed by Kaliski and Petykiewicz[13]. An increasing attention is being devoted to the interaction between magnetic field and strain field in a thermoelastic solid due to its many applications in the fields of geophysics, plasma physics and related topics. In all papers quoted above it was assumed that the interactions between the two fields take place by means of the Lorentz forces appearing in the equations of motion and by means of a term entering Ohm’s law and describing the electric field produced by the velocity of a material particle, moving in a magnetic field.

Many authors have considered the propagation of electromagneto-thermoelastic waves in an electrically and thermally conducting solid. Paria[14] discussed the propagation of plane magneto-thermoelastic waves in an isotropic unbounded medium under the influence of a uniform thermal field and with a magnetic field acting transversely to the direction of the propagation. Paria used the classical Fourier law of heat conduction, and neglected the electric displacement. Wilson[15] extended Paria’s results by introducing a component of the magnetic field parallel to the direction of the propagation. A comprehensive review of the earlier contributions to the subject can be found in Paria[16]. Among the authors who considered the generalized magneto-thermoelastic equations are Nayfeh and Nemat-Nasser[17] who studied the propagation of plane waves in a solid under the influence of an electromagnetic field. They obtained the governing equations in the general case and the solution for some particular cases. Choudhuri[18] extended these results to rotating media. Sherief and Ezzat[19] solved a thermal shock half-space problem using asymptotic expansions. Lately, Rajneesh Kumar and ManjheetSingh[20] solved the effect of rotation and imperfection on reflection and transmission of plane waves in anisotropic generalized thermoelastic media. R. Kumar, Praveen Ailawalia[22] studied moving load response in micropolar thermoelastic medium without energy dissipation possessing cubic symmetry, few attempts have been made to solve two-dimensional problems in this field Moncef Aouadi[23] introduced temperature dependence of an elastic modulus in generalized linear micropolar thermoelasticity.

When the magnetic field is very strong, the conductivity will be a tensor and the effect of Hall current cannot be neglected. The conductivity normal to the magnetic field is reduced due to the free spiraling of electrons and ions about the magnetic lines of force before suffering collisions and a current is induced in a direction normal to both the electric and magnetic fields. This phenomenon is called the Hall effect. In all of the above investigations, the effects of Hall current have not been considered.

In this work, we introduced a new model of the equations of the generalized magneto micropolar thermoelasticity in the presence of transverse magnetic field, taking into consideration the effects of Hall current and rotation, is applied to both generalizations, Lord–Shulman theory and Green–Lindsay theory, as well as to the coupled theory.

2. Basic Equations

In the dynamical of linear theory of magneto micropolar thermoelasticity permeated by an initial strong magnetic field of strength \( \mathbf{H} = (0, 0, H_o) \). We consider The elastic medium is rotating uniformly with an angular velocity \( \Omega \).

The governing equations of motion for homogenous, isotropic and elastic solid, when the Hall current and rotation effect is taken into account consists of

i. The equations of motion taking into account the Lorentz force have the form

\[
\sigma_{ij} \dddot{u}_j + \mu_o \epsilon_{ijk} \dot{H}_k = \rho \left( \dddot{u}_i + \Omega \times (\Omega \times u) + 2 \Omega \times \frac{\partial u}{\partial t} \right)
\]

where \( \sigma_{ij} \) is the force stress tensor, \( u_i \) is the components of the displacement vector, \( \varphi \) is the components of the micro-rotation vector, \( \mu_o \) is the couple stress tensor, \( \rho \) is the density, \( j \) is the microinertia, \( \epsilon_{ijk} \) is the permutation symbol, \( \mu_o \) is the magnetic permeability, and \( J \) is the conduction current density, given by The generalized Ohm’s law including Hall current:

\[
J = \frac{\sigma_0}{1 + m_e^2} \left( E + \mu_o \dot{u} \times H - \frac{1}{en_o} J \times H_o \right)
\]

where \( E \) is the intensity vector of the electric field, \( m (= \omega_e \tau_e) \) is the Hall parameter, \( \tau_e \) is the electron collision time, \(\omega_e (= e B_o/m_e) \) is the electronic frequency, \( e \) is the charge of an electron, \( B_o \) is the magnetic induction, \( m_e \) is the mass of the electron, \( \sigma_e \) \((e^2 n_e T/n_0)\), is the electrical conductivity and \( n_e \) is the number density of electrons.

ii. The constitutive equation

\[
\sigma_{ij} = \lambda u_{r,r} \delta_{ij} + 2 \mu \left( u_{i,j} + u_{j,i} \right)
\]

\[
+ k \left( u_{j,i} - e_{ij} \phi_t \right) - \gamma_1 \left( T + \nu T_s \right) \delta_{ij}
\]

\[
m_{ij} = \alpha \phi_{r,r} \delta_{ij} + \beta \phi_{i,j} + \gamma \phi_{j,i}
\]

where \( \lambda, \mu \) are Lamé’s constants, \( \alpha, \beta, \gamma \), and \( k \) are micropolar constants, \( T \) is the absolute temperature of the medium, \( \nu \) is the constant with dimension of time, called relaxation time, \( \gamma_1 \) is the material constant given by \( \gamma_1 = (3 \lambda + 2\mu + K) \alpha_i, \alpha_i \) being a coefficient of linear thermal expansion.

iii. The generalized equation of heat condition

\[
K T_{ij} = \rho c_p \left( T_i + \tau_o T_j \right) + T_o \gamma_1 \left( u_{i,j} + n_r n_o u_{i,j} \right)
\]

where \( K \) is thermal conductivity, \( c_p \) is the specific heat at constant temperature, \( T_o \) is the uniform temperature, \( \tau_o \) is an other relaxation time and \( n_o \) is a non-dimensional constant.
For L–S theory \( n_0 = 1, \tau_0 > 0, \nu = 0, \) and for G–L theory \( n_0 = 0, \tau_0 > 0, \nu > 0. \)

Substituting equations (4), and (5) into equation (5), and (6) we get

\[
\begin{align*}
(\lambda + \mu)u_{j,jj} + (\mu + k)u_{ij,j} + k e_{ijr} \phi_{r,j} - \gamma (T_j + v T_{it}) \\
+ \mu e_{jij}^* J_t H_j = \rho \left( u_{i,jt} + \Omega \times (\Omega \times u) + 2 \left( \Omega \times \frac{\partial u}{\partial t} \right) \right)
\end{align*}
\]

\[
(\alpha + \beta) \phi_{j,jj} + \gamma \phi_{ij,j} + k e_{ijr} u_{r,j} - 2k \phi_t =
\]

\[
a \rho \left( \phi_{i,it} + \left( \Omega \times \frac{\partial \phi}{\partial t} \right) \right)
\]

(7)

(8)

### 3. Formulation and Solution of the Problem

The rectangular Cartesian system \((x, y, z)\) having origin on the surface \(z = 0\) with \(z\)-axis vertical into the medium is introduction. In the following, we restrict our analysis parallel to \(xz\)-plane with \(z \geq 0, u_i = (u, 0, w), \phi_i = (0, \phi_2, 0)\) and \(\Omega = (0, \Omega, 0)\), we also assume that \(E = 0\), the generalized Ohm’s law gives \(J_y = 0\) everywhere in the medium.

The current density components \(J_x\) and \(J_z\) are given by:

\[
\begin{align*}
J_x &= \frac{\sigma_o B_o}{1 + m^2} \left( m \frac{\partial u}{\partial t} - \frac{\partial w}{\partial t} \right) \\
J_z &= \frac{\sigma_o B_o}{1 + m^2} \left( \frac{\partial u}{\partial t} + m \frac{\partial w}{\partial t} \right)
\end{align*}
\]

Let us introduce the following non-dimensional variables:

\[
\begin{align*}
\tilde{x} &= \eta_o \xi, \tilde{z} = \eta_o \zeta, \tilde{u} = u, \phi = \rho \eta_o \phi_0, \xi^* = \eta_o \xi, \eta_o \gamma T_0, \\
\tilde{\phi}_i &= \eta_o \phi_i, \tilde{\phi}_2 = \eta_o \phi_2, \tilde{\tau}_o = \eta_o \tau_o, \phi^* = \eta_o \phi, \Omega^* = \Omega
\end{align*}
\]

where \(\rho = K/\rho, \eta_o = \rho C_e/\kappa, \) and \(M\) is the Hartmann number or magnetic parameter.

The system of equations (6)-(8), using relations (9), and (10), takes the following form – dropping the asterisks for convenience-

\[
\begin{align*}
\frac{\partial^2 u}{\partial t^2} &= \frac{\lambda + \mu}{\rho \sigma_o^2} \frac{\partial e}{\partial x} + \frac{\mu + k}{\rho \sigma_o^2} \nabla^2 u - \frac{k}{\rho \sigma_o^2} \frac{\partial \phi_2}{\partial z} + \Omega^2 u \\
- 2 \frac{\partial w}{\partial t} - 2 \Omega \frac{\partial T}{\partial t} + \frac{M}{1 + m^2} \left( \frac{\partial u}{\partial t} + m \frac{\partial w}{\partial t} \right)
\end{align*}
\]

(11)

Introducing potential functions \(\Phi(x,z,t)\), and \(\Psi(x,z,t)\) defined by

\[
\begin{align*}
u &= \frac{\partial \Phi}{\partial x} = \frac{\partial \Psi}{\partial z} \\
e &= \nabla^2 \Phi, \quad \tilde{w} = \frac{\partial \Phi}{\partial z} = \nabla^2 \Psi
\end{align*}
\]

(21)

Substituting Eq. (21) into Eqs. (11)–(14) we obtain

\[
\begin{align*}
\left( \frac{\lambda + \mu}{\rho \sigma_o^2} \frac{\partial e}{\partial x} + \frac{\mu + k}{\rho \sigma_o^2} \nabla^2 u - \frac{k}{\rho \sigma_o^2} \frac{\partial \phi_2}{\partial z} + \Omega^2 u \\
- 2 \Omega \frac{\partial T}{\partial t} + \frac{M}{1 + m^2} \left( \frac{\partial u}{\partial t} + m \frac{\partial w}{\partial t} \right) \right)
\end{align*}
\]

\[
\begin{align*}
\frac{\sigma_o B_o}{\rho \sigma_o^2} \frac{\partial u}{\partial t} + \frac{\partial w}{\partial t} - \gamma \left( 1 + \nu \frac{\partial}{\partial x} \right) T = 0
\end{align*}
\]

\[
\begin{align*}
\frac{\partial \phi_2}{\partial z} = - \frac{\partial}{\partial z} \left( \frac{\partial \phi_2}{\partial z} \right)
\end{align*}
\]

(22)

(23)

(24)

(25)

Taking Laplace transform defined by the relation:

\[
\begin{align*}
\tilde{f}(s) &= \int_0^\infty e^{-st} f(t) dt
\end{align*}
\]
of both sides of (15)–(20) and (22)–(25) using the homogenous initial conditions, we obtain:

\[
\left(\frac{\lambda + 2\mu + k}{\rho c_o^2} \nabla^2 - \left(s^2 r_o - \frac{sM}{1 + m^2} \Omega^2\right)\right) \Phi = \phi \quad (26)
\]

\[
(1 + \nu s) \nabla^2 T + \left(\frac{Mm}{1 + m^2} - 2\Omega\right) \Psi = 0 \quad (27)
\]

\[
\left(\nabla^2 - \left(\frac{\rho}{\rho c_o^2} s^2 - 2k\right)\right) \Phi_2 = -k \nabla^2 \Psi \quad (28)
\]

\[
\left(\nabla^2 - (1 + r_o s)\right) T = \frac{\gamma^2 T_o}{k\Theta_0} (1 + n_0 r_o s) \nabla^2 \Phi \quad (29)
\]

\[
\sigma_{xx} = \left(\frac{\lambda + 2\mu + k}{\rho c_o^2} \right) \left(\frac{\partial \Pi}{\partial x} + \frac{\partial \Pi}{\partial z}\right) - \gamma (1 + \nu s) \nabla^2 \quad (30)
\]

\[
\sigma_{zz} = \left(\frac{\lambda + 2\mu + k}{\rho c_o^2} \right) \left(\frac{\partial \Pi}{\partial z} + \frac{\partial \Pi}{\partial x}\right) - \gamma (1 + \nu s) \nabla^2 \quad (31)
\]

\[
\sigma_{yy} = \lambda \left(\frac{\partial \Pi}{\partial x} + \frac{\partial \Pi}{\partial z}\right) - \gamma (1 + \nu s) \nabla^2 \quad (32)
\]

\[
\sigma_{xy} = \mu \left(\frac{\partial \Pi}{\partial x} + \frac{\partial \Pi}{\partial z}\right) \quad (33)
\]

\[
\bar{m}_{xy} = \beta \partial \bar{q}_2 \quad (33a)
\]

We now use the Fourier transform with respect to the space variable \(z\), defined by

\[
\tilde{T}^*(q) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{iqz} f(z) dz
\]

Taking the Fourier transform of both sides of (26)–(33)

\[
(\lambda^2 - \delta_i) \tilde{\Phi}^* = \delta_2 \tilde{T}^* - \delta_3 \tilde{\Phi}^* \quad (34)
\]

\[
(\lambda^2 - \delta_4) \tilde{\Psi}^* = \delta_5 \tilde{T}^* + \delta_6 \tilde{\Phi}^* \quad (35)
\]

\[
(\lambda^2 - \delta_7) \tilde{\Phi_2}^* = \delta_8 \left(D^2 - q^2\right) \tilde{\Phi}^* \quad (36)
\]

\[
(\lambda^2 - \delta_8) \tilde{T}^* = \delta_9 \left(D^2 - q^2\right) \tilde{\Phi}^* \quad (37)
\]

\[
\tilde{\Phi}_{xx}^* = \left(\lambda + 2\mu + k\right) \tilde{D} \tilde{w}^* + iq\lambda \tilde{w}^* - \gamma (1 + \nu s) \tilde{T}^* \quad (38)
\]

\[
\tilde{\Phi}_{zz}^* = iq \left(\lambda + 2\mu + k\right) \tilde{w}^* + \lambda \tilde{D} \tilde{w}^* - \gamma (1 + \nu s) \tilde{T}^* \quad (39)
\]

\[
\tilde{\Phi}_{yy}^* = \lambda \left(\tilde{D} \tilde{w}^* + iq\tilde{w}^*\right) - \gamma (1 + \nu s) \tilde{T}^* \quad (40)
\]

\[
\tilde{\Phi}_{xz}^* = \mu \tilde{D} \tilde{w}^* + i\mu \tilde{w}^* \quad (41)
\]

\[
\tilde{w}_{xy}^* = \beta D \tilde{q}_2^* \quad (42)
\]

\[
\tilde{w}_{zy}^* = i\gamma q \tilde{\Phi}_2^* \quad (43)
\]

where

\[
\delta_1 = \frac{\rho c_o^2}{\lambda + 2\mu + k} \left(s^2 r_o - \frac{sM}{1 + m^2} \Omega^2\right) + q^2, \quad \delta_2 = \frac{s\rho c_o^2 (1 + \nu s)}{\lambda + 2\mu + k}
\]

\[
\delta_3 = \frac{s\rho c_o^2}{(\lambda + 2\mu + k)} \left(Mm + 2\Omega\right)
\]

\[
\delta_4 = \frac{\rho c_o^2}{\mu + k} \left(s^2 r_o - \frac{sM}{1 + m^2} \Omega^2\right) + q^2
\]

\[
\delta_5 = \frac{s k}{\mu + k}, \quad \delta_6 = s\rho c_o^2 Mm \left(\frac{Mm}{1 + m^2} - 2\Omega\right)
\]

\[
\delta_7 = \left(\frac{\rho}{\gamma} s^2 - 2k\right) q^2
\]

\[
\delta_8 = (1 + r_o s) q^2, \quad \delta_9 = \frac{\gamma^2 T_o}{K\Theta_0 d}(1 + n_0 r_o s)
\]

and the operator D means the derivative with respect to \(x\). On Eqs. (34)–(37) and after some simplification, we arrive at the following eighth order differential equation satisfied by \(\tilde{\Phi}^*, \tilde{T}^*, \tilde{\Phi}^*\) and \(\tilde{\Phi}_2^*\):

\[
\left[D^8 - AD^6 + BD^4 - CD^2 + F\right] \left(\tilde{\Phi}^*, \tilde{T}^*, \tilde{\Phi}^*, \tilde{\Phi}_2^*\right) = 0 \quad (44)
\]

where

\[
A = \delta_1 + \delta_2 \delta_3 + \delta_4 + k\delta_5 + \delta_7 + \delta_8,
\]

\[
B = \delta_1 \delta_8 + \delta_2 \delta_9 q^2 + \delta_4 \delta_7 - \delta_5 q^2
\]

\[
C = (\delta_4 \delta_7 - \delta_5 q^2)(\delta_1 + \delta_8 + \delta_9)
\]

\[
+ (\delta_8 \delta_9 q^2)^2 (\delta_4 + \delta_7 - k\delta_5)
\]

\[
F = (\delta_8 \delta_9 + \delta_2 \delta_9 q^2)(\delta_4 \delta_7 - \delta_5 q^2)
\]

The solution of the Eq. (44) satisfying the radiation conditions that \(\tilde{\Phi}^*, \tilde{T}^*, \tilde{\Phi}_2^*\) and \(\tilde{\Phi}^*\) tend to zero as \(x\) tends to infinity can be written as

\[
\tilde{\Phi}^*(x, q, s) = \sum_{i=1}^{4} \left(1, \ell_i, \ell_2, \ell_3, \ell_4\right) A_i e^{-k_i x} (45)
\]

where

\[
\ell_i = \frac{\delta_2 \delta_9 (k_i - q^2) - (\delta_4 \delta_7 - \delta_5) (k_i^2 - \delta_i)}{\delta_3 (k_i^2 - \delta_8)}, \quad i=1,2,3,4
\]

\[
\ell_2 = \frac{(k_i^2 - \delta_8) \delta_3 \delta_9 (k_i^2 - q^2) - (k_i^2 - \delta_8) (k_i^2 - \delta_7)}{\delta_9 \delta_3 (k_i^2 - \delta_8)}
\]

\[
\ell_3 = \frac{\delta_6 \delta_9 (k_i^2 - q^2)}{(k_i^2 - \delta_8)}
\]

and \(k_i (i=1,2,3,4)\) are the characteristic roots of the characteristic equation (36) which is

\[
k^8 - Ak^6 + Bk^4 - Ck^2 + F = 0,
\]

Eq. (21) together with Eq. (45), immediately give
heating, which depends on the coordinate z.

\[ T(0, z, t) = G(t) F(z) \]  
(48)

where \( F(z) \) is an arbitrary function of \( z \) and \( G(t) \) is a function defined as Misra et al.,[25]:

\[
G(t) = \begin{cases} 
T_0 & t \leq 0 \\
\frac{t}{t_o} & 0 < t \leq t_o \\
T_1 & t > t_o 
\end{cases}
\]  
(49)

where \( t_o \) indicates the length of time to rise the heat and \( T_1 \) is constant, this means that the boundary of the half-space, which is initially at rest and has a fixed temperature \( T_0 \), is suddenly raised to a temperature equal to the function \( G(t)F(z) \) and maintained at this temperature from then on.

Applying the Laplace and Fourier transforms to both sides of Eq. (42), we obtain

\[ T^*(0, q, s) = \bar{G}(s) F^*(q) \]  
(50)

where \( \bar{G}(s) = \frac{T_1}{t_o s^2} \)

We assume that, on the boundary \( x = 0 \) the displacement \( u \) of the body does not depend on \( x \), hence we have \( Du(0, z, t) = 0 \) and the medium is subjected to a rough and rigid foundation enough to prevent the displacement \( w \) at any time and any point of \( z \), so also we have \( w(0, x, t) = 0, m_{2y} = 0. \)

Applying the Laplace and Fourier transforms, we get

\[ DU^* = Dw^* = m_{2y}^* = 0 \]  
(51)

Using the values in expressions (50), and (51), the above general expressions reduce in our case to the following form

\[ u^*(x, q, s) = \sum_{j=1}^{4} (iq \ell_1 j - k_j) A_j e^{-k_j x} \]  
(52)

\[ v^*(x, q, s) = \sum_{j=1}^{4} (iq + k_j \ell_1 j) A_j e^{-k_j x} \]  
(53)

\[ T^*(x, q, s) = \sum_{j=1}^{4} \ell_3 j A_j e^{-k_j x} \]  
(54)

\[ \phi_{2y}^*(x, q, s) = \sum_{j=1}^{4} \ell_2 j A_j e^{-k_j x} \]  
(55)

4. Application

The boundary of the half-space is affected by ramp-type heating, which depends on the coordinate \( z \) and the time \( t \) of the form

\[ T(0, z, t) = G(t) F(z) \]

where \( F(z) \) is an arbitrary function of \( z \) and \( G(t) \) is a function defined as Misra et al.,[25]:

\[
G(t) = \begin{cases} 
T_0 & t \leq 0 \\
\frac{t}{t_o} & 0 < t \leq t_o \\
T_1 & t > t_o 
\end{cases}
\]

where \( t_o \) indicates the length of time to rise the heat and \( T_1 \) is constant, this means that the boundary of the half-space, which is initially at rest and has a fixed temperature \( T_0 \), is suddenly raised to a temperature equal to the function \( G(t)F(z) \) and maintained at this temperature from then on.

Applying the Laplace and Fourier transforms to both sides of Eq. (42), we obtain

\[ T^*(0, q, s) = \bar{G}(s) F^*(q) \]  
(50)

where \( \bar{G}(s) = \frac{T_1}{t_o s^2} \)

We assume that, on the boundary \( x = 0 \) the displacement \( u \) of the body does not depend on \( x \), hence we have \( Du(0, z, t) = 0 \) and the medium is subjected to a rough and rigid foundation enough to prevent the displacement \( w \) at any time and any point of \( z \), so also we have \( w(0, x, t) = 0, m_{2y} = 0. \)

Applying the Laplace and Fourier transforms, we get

\[ DU^* = Dw^* = m_{2y}^* = 0 \]  
(51)

Using the values in expressions (50), and (51), the above general expressions reduce in our case to the following form

\[ u^*(x, q, s) = \sum_{j=1}^{4} (iq \ell_1 j - k_j) A_j e^{-k_j x} \]  
(52)

\[ v^*(x, q, s) = \sum_{j=1}^{4} (iq + k_j \ell_1 j) A_j e^{-k_j x} \]  
(53)

\[ T^*(x, q, s) = \sum_{j=1}^{4} \ell_3 j A_j e^{-k_j x} \]  
(54)

\[ \phi_{2y}^*(x, q, s) = \sum_{j=1}^{4} \ell_2 j A_j e^{-k_j x} \]  
(55)

5. Particular Cases

i- If \( m = 0 \), in Eqs. (52)–(61), we obtain the components of displacements and stresses in magneto-micropolar generalized thermoelastic with rotating medium without Hall current effect.

ii- Taking Hartmann number \( M = 0 \), in Eqs. (52)–(61), we obtain the components of displacements and stresses in micropolar generalized thermoelastic with rotating medium.

iii. If the effect of rotation is absent (\( \Omega = 0 \)), in Eqs. (52)–(61), we obtain the components of displacements and stresses in micropolar generalized thermoelastic medium with the following changed values of \( \delta_1, \delta_3, \delta_4, \) and \( \delta_6 \) as
\[
\delta_1 = \frac{s \rho c^2}{\lambda + 2\mu + k} \left( s \tau_o + \frac{M}{1 + m^2} \right) + q^2.
\]
\[
\delta_3 = \frac{s \rho c^2}{(\lambda + 2\mu + k)(1 + m^2)}.
\]
\[
\delta_4 = \frac{s \rho c^2}{\mu + k} \left( s \tau_o + \frac{M}{1 + m^2} \right) + q^2.
\]
\[
\delta_6 = \frac{s \rho c^2}{\mu + k} \left( s \tau_o + \frac{M}{1 + m^2} \right) + q^2.
\]
iv. Taking \(n_0 = 1, \tau_o > 0, \nu = 0\) in Eqs. (52)–(61), we obtain the corresponding expressions for magneto-micropolar thermoelastic with rotating for L–S theory.

v. Taking \(n_0 = 0, \tau_o > 0, \nu > 0\) in Eqs. (52)–(61), we obtain the corresponding expressions for magneto-micropolar thermoelastic with rotating for G–L theory.

vi. Taking, \(n_0 = 0, \tau_o = 0, \nu = 0\) we obtain the corresponding expressions for magneto-micropolar coupled thermoelastic with rotating medium for (C–T theory.

### 6. Inversion of the Transforms

To obtain the solution of the problem in the physical domain \((x,y,t)\), we have to invert the iterated transforms in Eqs. (52)–(61). These expressions can be formally expressed as functions of \(x\) and the parameter of the Fourier and Laplace transforms \(q\) and \(s\) of the form \(\mathcal{F}^q(x,q,s)\).

First, we invert the Fourier transform using the inversion formula given previously. This gives the Laplace transform expression \(\mathcal{F}^q(x,q,s)\) of the function \(h(x,y,t)\) as

\[
\mathcal{F}^q(x,q,s) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-iqy} h(x,y,s) dq
\]

\[
= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \left( \cos(qy)f_e + i\sin(qy)f_o \right) dq
\]

where \(f_e\) and \(f_o\) denote the even and the odd parts of the function \(h(x,q,s)\) respectively.

We shall now outline the numerical inversion method used to find the solution in the physical domain. For fixed values of \(x\), \(y\), and \(q\) the function inside braces in the last integral can be considered as a Laplace transform \(\mathcal{G}(s)\) of some function \(g(t)\).

The inversion formula for the Laplace transform can be written as

\[
g(t) = \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} \mathcal{G}(s) ds
\]

where \(c\) is an arbitrary real number greater than all the parts of the singularities \(\mathcal{G}(s)\). Taking \(s = c + iy\), the above integral takes the form

\[
g(t) = \frac{e^{ct}}{2\pi} \int_{-\infty}^{\infty} e^{iyt} \mathcal{G}(c+iy) dy
\]

Expanding the function \(h(t) = \exp(-ct)g(t)\) in a Fourier series in the interval \([0, 2L]\), we obtain the approximate formula.

\[
g(t) = g_\infty(t) + ED
\]

where

\[
g_\infty(t) = \frac{1}{2} c_0 + \sum_{k=1}^{\infty} c_k \text{ for } 0 \leq t \leq 2L
\]

and

\[
c_k = \frac{e^{ct}}{L} \Re \left[ \frac{e^{ik\pi t/L}}{G(c + ik\pi t/L)} \right]
\]

Using the above formula to evaluate \(g(t)\), we introduce a truncation error \(E_T\) which must be added to the discretization error to produce the total approximation error.

Two methods are used to reduce the total error. First the “Korrektur” method is used to reduce the discretization error. Next, the \(e\)-algorithm is used to reduce the truncation error and hence to accelerate convergence.

The Korrecktur method uses the following formula to evaluate the function \(g(t)\):

\[
g(t) = g_\infty(t) - e^{2\pi L} g_\infty(2L + t) + ED
\]

where the discretization error \(|E_D| < |E_T|\). Thus, the approximate value of \(g(t)\) becomes

\[
g_N(t) = \frac{1}{2} c_0 + \sum_{k=1}^{N} c_k \text{ for } 0 \leq t \leq 2L
\]

Using the above formula to evaluate \(g(t)\), we introduce a truncation error \(E_T\) which must be added to the discretization error to produce the total approximation error.

Two methods are used to reduce the total error. First the “Korrektur” method is used to reduce the discretization error. Next, the \(e\)-algorithm is used to reduce the truncation error and hence to accelerate convergence.

The Korrecktur method uses the following formula to evaluate the function \(g(t)\):

\[
g(t) = g_\infty(t) - e^{2\pi L} g_\infty(2L + t) + ED
\]

where the discretization error \(|E_D| < |E_T|\). Thus, the approximate value of \(g(t)\) becomes

\[
g_N(t) = \frac{1}{2} c_0 + \sum_{k=1}^{N} c_k \quad \text{for} \quad 0 \leq t \leq 2L
\]

N’ is an integer such that \(N’ < N\). We shall now describe the \(e\)-algorithm that is used to accelerate the convergence of the series in Eq. (64).

Let \(N = 2q + 1\) where \(q\) is a natural number, and let

\[
s_m = \sum_{k=1}^{m} c_k
\]

be the sequence of partial sums of Eq. (64). We define the \(e\)-sequence by

\[
e_{o,m} = 0, \quad e_{1,m} = 0
\]

and

\[
e_{p+1,m} = \frac{e_{p,m+1} + 1}{e_{p+1,m} - e_{p,m}}, \quad p = 1, 2, 3, ...
\]

it can be shown that the sequence \(e_{1,1}, e_{1,2}, e_{3,1}, \ldots, e_{N,1}\), converges to \(f(x,y,t) + ED - c/2\) faster than the sequence of partial sums \(s_m\) \((m = 1, 2, 3, \ldots)\).

The actual procedure used to invert the Laplace transform consists of using Eq. (65) together with the \(e\)-algorithm. The values of \(c\) and \(L\) are chosen according to the criteria outlined Honig and Hirdes[24].
7. Numerical Results and Discussion

The analysis is conducted for a magnesium crystal-like material. Following reference [25], the values of physical constants are:

\[ \lambda = 9.4 \times 10^{10} \text{ Nm}^{-2}, \mu = 4.0 \times 10^{10} \text{ Nm}^{-2}, \rho = 1.74 \times 10^{3} \text{ gm/cm}^{3}, \gamma = 0.779 \times 10^{4} \text{ N}, j = 0.2 \times 10^{-15} \text{ cm}^{2}, \]
\[ c_{E} = 1.04 \times 10^{3} \text{ kgm}^{-3}, K^{*} = 1.7 \times 10^{2} \text{ Jm}^{-1}\text{deg}^{-1}, T_{o} = 298 \text{ K}, \]
\[ \nu = 3.68 \times 10^{6} \text{ Nm}^{-2}\text{deg}^{-1}, \tau_{o} = 0.02, n_{o} = 0.05. \]

We consider the following electric constants for our problem:

\[ \sigma_{o} = 9.36 \times 10^{5} \text{ Col}^{2}/\text{Cal.cm.sec}, H_{o} = 10^{5} \text{ Col/cm.sec} \]

The computations are carried out for the non-dimensional time \( t = 0.1 \), strip width \( a = 0.9 \times 10^{-3} \), and on the surface plane \( z = 0 \). The distribution of non-dimensional transverse displacement \( u \), normal displacement \( w \), normal force stress \( \sigma_{zz} \), tangential couple stress \( m_{zy} \), temperature distribution \( T \), normal current density \( j_{x} \) and \( j_{z} \) have been shown in Figs. 1–7.

The solid line represents magneto-micropolar generalized thermoelastic with Hall current effect and rotating medium MMGT(HR) and large dashes line represents magneto-micropolar generalized thermoelastic with Hall current effect MMGT(H), while small dashes line represents magneto-micropolar generalized thermoelastic in rotating medium without Hall current effect MMGT(R). The dot line represents magneto-micropolar generalized thermoelastic without Hall current effect and rotating medium MMGT.

Fig. 1 Studying the effect of Hall parameter \( m \) on the temperature distribution against \( y \) for, from this figure we see that all the curves start from the same value 1 at \( x = 0.0 \) then decreases till it tends to zero at \( x = 2 \), we observe that from this figure the temperature \( T \) decrease in the case MMGT(HR) in comparison to curve MMGT(R), while increases in comparison to curves MMGT and MMGT(H). The effect of parameter \( m \) on the transverse displacement \( u \) is presented in Fig. 2. It is noticed that from the graphic representation of the transverse displacement that the values are oscillatory for all the cases in the whole range and the values of \( u \) remain higher near the boundary condition in magnitude for case MMGT(HR) as compared with the values for all cases and then increases. Fig. 3 describes the variations of the normal displacement \( w \) under the effect of all parameters, it is noticed that the normal displacement \( w \) records values lower in case MMGT(HR) as compared with the values for all cases. It is shown in Fig. 4 that the values of normal force stress for MMGT(H) and MMGT lie in a very short range. The variation for all cases being oscillatory in nature are comparable in magnitude and the magnitude of these oscillations decrease with increase in horizontal distance \( x \). Fig. 5 shows that the Variation of couple stress \( m_{zy} \) decreases as \( m \) increases MMGT(HR). The figure indicates that \( m_{zy} \) records values higher in case MMGT(H) as compared with the values of case MMGT(R) and all cases oscillations about \( y \)-axes.
Figs. 6, 7 describe the variations of two components of density component $J_x$ and $J_z$ respectively, it is evident that the values of both fields are decreased in the MMGT(HR) as compared with the values for cases MMGT and MMGT(H).
