INTRODUCTION

The cellular phone user in India by 2009-10 reached to 584.32 million for communication. These cellular phones are hand-held and constant handling by different users exposes it to a wide array of microbes as well as a potential carrier for their transmission [1]. Staphylococci are recognized nosocomial pathogens of cellular phone causing skin, intra-abdominal and pelvic site wound infections [2, 3]. Moreover, biofilm formation by Staphylococci species has been depicted as a predominant virulence factor. The cellular phones of 70 different users including staff and students of the department of microbiology, OUAT, Bhubaneswar, Odisha were selected for this study. The isolation of bacteria was carried out by standard swab culture method using nutrient agar (NA). Individual bacterial isolates were sub-cultured on NA medium to obtain pure culture and preserved at 4 °C for further characterization. Based on Gram variability, the Gram-positive cocci were selected for different characterizations such as blood haemolysis, indole, catalase, oxidase, coagulase, mannitol and antibiotic sensitivity. Further, the isolates were identified up to generic level from morpho-physiological characterization using Bergey’s manual of determinative bacteriology [4].

METHODS

Sample collection and bacteriological analysis

The cellular phones of 70 different users including staff and students of the department of microbiology, OUAT, Bhubaneswar, Odisha were selected for this study. The isolation of bacteria was carried out by standard swab culture method using nutrient agar (NA). Individual bacterial isolates were sub-cultured on NA medium to obtain pure culture and preserved at 4 °C for further characterization. Based on Gram variability, the Gram-positive cocci species has been depicted as a predominant virulence factor. The cellular phone user in India by 2009-10 reached to 584.32 million for communication. These cellular phones are hand-held and constant handling by different users exposes it to a wide array of microbes as well as a potential carrier for their transmission [1]. Staphylococci are recognized nosocomial pathogens of cellular phone causing skin, intra-abdominal and pelvic site wound infections [2, 3]. Moreover, biofilm formation by Staphylococci species has been depicted as a predominant virulence factor. The cellular phones of 70 different users including staff and students of the department of microbiology, OUAT, Bhubaneswar, Odisha were selected for this study. The isolation of bacteria was carried out by standard swab culture method using nutrient agar (NA). Individual bacterial isolates were sub-cultured on NA medium to obtain pure culture and preserved at 4 °C for further characterization. Based on Gram variability, the Gram-positive cocci were selected for different characterizations such as blood haemolysis, indole, catalase, oxidase, coagulase, mannitol and antibiotic sensitivity. Further, the isolates were identified up to generic level from morpho-physiological characterization using Bergey’s manual of determinative bacteriology [4].

Chemicals and reagents

Most of the culture media used for the isolation and characterization of bacteria were prepared as per the manufacturer’s instruction by using double distilled water. All the culture media and chemicals were procured from Hi-media laboratories private limited, Mumbai.

Antibiogram profile of Staphylococcus species

The Staphylococcus species were subjected to antibiotic sensitivity assay against methicillin (10 mcg), vancomycin (5 mcg), linozolid (30 mcg), erythromycin (15 mcg), tetracycline (30 mcg), penicillin (10 mcg), ceftriaxone-tazobactum (30-10 mcg), amoxiclav (30 mcg), cefixime (5 mcg), imipenem (10 mcg), co-trimazole (25 mcg), clindamycin (2 mcg) and rifampicin (30 mcg) by disc diffusion method [9].

Molecular characterization of Staphylococcus species

An attempt was made to characterize the methicillin and vancomycin-resistant Staphylococcus species through 16s rDNA analysis [10]. Briefly, the extracted DNA was quantified by using nano-drop and stored at −20 °C in TE buffer till further use. The 16s rDNA sequencing was done through Eurofins Labs Ltd., Ahmedabad, India, using forward and reverse 27F (AGA GTG TTA CCG CGG CTG AGG) and 1492R (TAC GGT TAT CTT GGT AGC ACT T) primers BDT v3.1 cycle sequencing kit on ABI 3730xl genetic analyzer. The consensus sequence of 16s rDNA was analyzed by Bio-Edit software.
v7.0.5.3 and submitted to NCBI (http://blast.ncbi.nlm.nih.gov/blast.cgi) for generation of accession number. The 16S rDNA consensus sequence of the isolate was subjected to multiple sequence analysis using ClustalW v1.6. The phylogenetic tree was constructed using a neighbour-joining method by MEGA v6.0 (molecular evolutionary genetics analysis) software [11]. The resultant phylogenetic tree topologies were evaluated by bootstrap analysis of neighbour-joining data sets based on 1000 re-samplings.

**Biofilm production by Staphylococcus species**

The qualitative assay of biofilm formation by *Staphylococcus* species was conducted using tube congo red plate method [12] and followed by scanning electron microscopic (SEM) analysis [13]. Briefly, the fresh culture of *Staphylococcus* species was inoculated to brain heart infusion (BHI) broth containing 0.5% sucrose and incubated at 37 °C for 24-48 h. The specimens were immersed in Karnovsky’s solution for 30 min. The fixed specimens were rehydrated using different grade ethanol and transferred to butyl alcohol, freeze-dried and coated with gold for SEM observation at 15000X magnification (FE-SEM Quanta 200 FEG).

**Antibacterial activity of disinfectants and essential oils against *Staphylococcus* species**

The antibacterial activity of some common disinfectants like dettol, suthol, hand sanitizer and extracted essential oils of cinnamon (*Cinnamon zeylanicum*), nutmeg (*Myristica fragrance*) and neem (*Azadirachta indica*) oil was evaluated by disc diffusion method [9]. Briefly, the day old cultures of bacterial isolates were uniformly spread on muller-hinton (MH) agar plate using a sterile cotton swab. Then, sterile discs containing 20 µl of each disinfectant or essential oil was placed separately in the MH agar plate and incubated at 37 °C for 24 h. After the incubation period, plates were observed for zones of inhibition around the discs indicating the positive antibacterial activity of the agents. Further, SEM observation (10000X magnifications) was also carried out to observe the effect of disinfectant and essential oil against *Staphylococcus* species.

**RESULTS AND DISCUSSION**

**Bacteriological analysis of cellular phones**

Cellular phones provide an ideal environment for colonization of various non-pathogenic and pathogenic microbes as it generates heat and has numerous slits for the accumulation of dust particles and moisture [14]. In this investigation, we observed a high degree of bacterial colonization including *Staphylococcus* species on cellular phones. In total 120 bacteria were isolated from 70 different cellular phone users including stafﬁs and students of the department of microbiology, OUAT, Bhubaneswar, Odisha. Results of the research work depicted a high degree (100%) of bacterial association with cellular phones including 5.16% were Gram-positive cocci, 40.80% Gram positive rod and 7.50% Gram negative rod respectively. Out of 62 Gram positive cocci (fig. 1a), 25 were β-hemolytic (fig. 1b); among them, 88% were coagulase positive. The β-hemolytic and coagulase positive bacteria belong to the genera *Staphylococcus* as confirmed from their morpho-physiological characterizations. In contrast to our results, an association of different bacteria such as *Staphylococcus aureus*, *Enterococcus faecalis*, *Pseudomonas aeruginosa*, *Escherichia coli*, *Klebsiella sp.*, *Streptococcus sp.*, *Bacillus cereus*, *Proteus mirabilis*, *Salmonella sp.*, *Shigella sp.* with cellular phones were also reported earlier [15, 14]. In addition, healthcare workers hand and cellular phones were also contaminated with various types of bacteria including nosocomial pathogens [6]. Moreover, colonization of these bacteria on cellular phones could be due to transmission of bacteria from hand, mouth, ear and skin during handling and aerosols.

**Antibiotic profile of *Staphylococcus* species**

The antibiogram pattern of *Staphylococcus* species indicated that 10% of the bacterial isolates were resistant to methicillin. Among them, *Staphylococcus* sp. 52N6, *Staphylococcus* sp. 53N9 and *Staphylococcus* sp. 53N6 were resistant to both methicillin and vancomycin. Notably, *Staphylococcus* sp. 53N6 was resistant to various third generation antibiotics such as amoxiclav, clindamycin, vancomycin, erythromycin, methicillin, linozolid, penicillin used in the study. This is the first report demonstrating the association of multi-drug resistant *Staphylococcus* sp. 53N6 with the cellular phones. Similarly, colonization of 37.7%, 3.84% and 2.4% methicillin-resistant *Staphylococcus* species with cellular phones of different users was also reported before [6, 16, 17].

**Molecular identification of the *Staphylococcus* species**

The 16s rDNA sequence of *Staphylococcus* sp. 53N6 was subjected for BLAST analysis and the best twenty ﬁve hits were selected on the basis of highest percentage of similarity and lowest expected value. Further, the phylogenetic tree was constructed using these twenty-five homologous sequences and sequence of *Staphylococcus* sp. 53N6 (fig. 2). The in silico analysis revealed that the *Staphylococcus* sp. 53N6 99% similar with *Staphylococcus arlettae* VIT-RJ1 (KJ716448.1). The identiﬁed bacterium is *Staphylococcus* sp. strain CPC53N6 with accession no. KX858346.

**Biofilm formation by *Staphylococcus* species**

Formation of black colored colonies on congo red agar plate (fig. 3a) by *Staphylococcus* sp. strain CPC53N6 indicating biofilm formation as compared to control that exhibiting red colonies with dry crystalline morphology. Similarly, biofilm formation by the *Staphylococcus* sp. strain CPC53N6 was observed using tube method (fig. 3b). In addition, biofilm formation by the bacterial isolate was also conﬁrmed from SEM studies, which indicate that the biofilms were composed of aggregated cocci and ﬁbriform extracellular matrix-like structures (fig. 3d) as compared to control (fig. 3c). The virulence factor of *Staphylococcus* sp. strain CPC53N6 was conﬁrmed from biofilm formation. This enhances their resistance to antibiotics and also contributes in genetic exchange. Although earlier studies reported that [2, 18] biofilm production is more commonly associated with clinical isolates than non-clinical one. Thus, an association of such type of potential opportunistic pathogens on cellular phones has a significant concern. Increased attention should be given to reduce contamination of *Staphylococcal* strains from cellular phones using good hand hygiene practices.

**Fig. 1: a. Micrograph of *Staphylococcus* sp. strain CPC53N6, and b. β-hemolytic *Staphylococcus* sp. strain CPC53N6**
Antibacterial activity of disinfectant and essential oils against *Staphylococcus* species

This study revealed that all the β-haemolytic and coagulase positive *Staphylococcus* species were sensitive to dettol, cinnamon oil, suthol and nutmeg oil. However, most of the *Staphylococcus* species were moderately sensitive to neem oil and hand sanitizer (fig. 4 and 5a). Thus, the growth of *Staphylococcus* species was drastically reduced by dettol and cinnamon oil than other disinfectants used. Moreover, an SEM study was also confirmed regarding disruption of clustered cell arrangements and biofilm of *Staphylococcus* sp. strain CPC53N6 in presence of dettol (fig. 5d) and cinnamon oil (fig. 5c) as compared with control (fig. 5b) [19, 20]. Presence of chloroxylenol and isopropyl alcohol in dettol [21] and cinnamaldehyde and eugenol in cinnamon oil [22, 23] inhibits the growth of bacterial isolates. Although different disinfection strategies including the application of isopropyl alcohol or ethyl alcohol [24, 17] and ultraviolet radiation [25] were reported earlier, but ultraviolet radiation [26] is not so effective against a wide array of microbes. Thus, naturally available cinnamon oil can be an alternative of dettol, which not only kills the multi-drug resistant bacteria in vitro but also can secure highly sensitive cellular phone-like devices, as there is a growing demand for the search of natural antimicrobial compounds and disinfectants against costly harmful antimicrobial drugs or disinfectants.
In conclusion, cellular phones were highly contaminated by a wide array of bacteria including Staphylococcus species with a high degree of resistance to various third generation antibiotics. This suggests the potentiality of cellular phones as a carrier for transmission of infections with promising public health implications. As a matter of fact, we suggest an active preventive strategy like routine hand hygiene practices along with decontamination of cellular phones with volatile natural products cinnamon oil, which will reduce cross-infection without impeding the normal functions. On the other hand, cellular phone surface should be designed using cinnamon oil based antimicrobial additive materials to reduce transmission of microbes as well as spreading of various diseases in future.

ACKNOWLEDGEMENT

The authors are grateful to the head, Department Microbiology and Central Laboratory, OUAT, Bhubaneswar for providing facilities to undertake this research work.

AUTHORS CONTRIBUTIONS

The experimental studies including literature search were conducted by Swati Pattnaik, Shatabdi Mishra and Dr. Swati Mohapatra. The manuscript was prepared by Swati Pattnaik and Sudipto Maity. Planning of experiment and manuscript reviewing were carried out by Dr. Chandri Chran Rath and Dr. Deviprasad Samantaray.

CONFLICT OF INTERESTS

The authors have no conflict of interest to declare.
