ESSENTIAL INPUTS AND MINIMAL TREE AUTOMATA

IVO DAMYANOV AND SLAVCHO SHTRAKOV

Abstract. In the paper we continue studying essential inputs of trees and automata initiated in [10]. We distinguish the behavior of the essential inputs of trees and essential variables for discrete functions. Strongly essential inputs of trees are introduced too. It is proved that if a tree and an automaton have at least two essential inputs then they have at least one strongly essential input. A minimization algorithm for trees and automata is proposed. Various examples for application in Computer Science are shown.

AMS, subject classification: 03D05, 68Q70, 03D15, 06B25
Key words and phrases: Tree, Tree Automata, Essential Input.

1. Introduction

Tree automata are designed in context of circuit verification and logic programming. In the 1970’s some new results were obtained concerning tree automata, as an important part of theoretical basis of the computing and programming. So, since the end of 1970’s tree automata have been used as powerful tools in program verification. There are many results connecting properties of programs or type systems or rewrite systems with automata. In the papers of S.Jablonsky [7], A.Salomaa [9], K.Chimev [2] etc. the theory of essential variables for discrete functions was developed. Some new interpretation for essential, and strongly essential variables were introduced in [4]. The concept of essential variables and separable sets of variables has been introduced for terms in Universal algebra by K. Denecke and Sl. Shtrakov [12]. In [10] the second author of this paper initiate the investigation of the behavior or essential input variables for tree automata and trees.

2. Basic Definitions and Notations

Let $F$ be any finite set, the elements of which are called operation symbols. Let $\tau : F \to N$ be a mapping into the non negative integers; for $f \in F$, the number $\tau(f)$ will denote the arity of the operation symbol $f$. The pair $(F, \tau)$ is called type or signature. Often if it is obvious what the set $F$ is, we will write "type $\tau$". The set of symbols of arity $p$ is denoted by $F_p$. Elements of arity 0, 1, \ldots, $p$ respectively are called constants(nullary), unary,\ldots,$p$-ary symbols. We assume that $F_0 \neq \emptyset$.

Definition 1. Let $X_n = \{x_1, \ldots, x_n\}$, $n \geq 1$, be a set of variables with $X_n \cap F = \emptyset$. The set $W_\tau(X_n)$ of $n$-ary terms (trees) of type $\tau$ with variables from $X_n$ is defined as the smallest set for which:

(i) $F_0 \cup X_n \subseteq W_\tau(X_n)$
(ii) if $p \geq 1$, $f \in F_p$ and $t_1, \ldots, t_p \in W_\tau(X_n)$ then $f(t_1, \ldots, t_p) \in W_\tau(X_n)$. 

By $W_\tau(X)$ we denote the following set 

$$W_\tau(X) := \cup_{n=1}^\infty W_\tau(X_n),$$

where $X = \{x_1, x_2, \ldots\}$. If $X = \emptyset$ then $W_\tau(X)$ is also written $W_\tau$. Terms in $W_\tau$ are called ground terms.

Let $t$ be a term. By $\text{Var}(t)$ the set of all variables from $X$ which occur in $t$ is denoted. The elements of $\text{Var}(t)$ are called input variables or inputs for $t$.

Let $t$ be a term and suppose we are given a term $s_x$ for every $x \in X$. The term denoted by $t(x \leftarrow s_x)$, is obtained by substituting in $t$, simultaneously for every $x \in X$, $s_x$ for each occurrence of $x$.

If $t, s_x \in W_\tau(X)$ then $t(x \leftarrow s_x) \in W_\tau(X)$.

Any subset $L$ of $W_\tau(X)$ is called term-language or tree-language.

Let $t$ be a term of type $\tau$. We define the depth of $t$ inductively as follows:

(i) if $t \in X \cup F_0$ then $\text{Depth}(t) = 0$;

(ii) if $t = f(t_1, \ldots, t_n)$ then $\text{Depth}(t) = \max\{\text{Depth}(t_1), \ldots, \text{Depth}(t_n)\} + 1$.

Let $N$ be the set of natural numbers and $N^*$ be the set of finite strings over $N$.

The set $N^*$ is naturally ordered by $\forall \overline{m}, \overline{n} \in N^* \quad \overline{m} \preceq \overline{n} \iff \overline{m}$ is a prefix of $\overline{n}$.

A term $t \in W_\tau(X)$ may be viewed as a finite ordered tree, the leaves of which are labelled with variables or constant symbols and the internal nodes are labelled with operation symbols of positive arity, with out-degree equal to the arity of the label, i.e. a term $t \in W_\tau(X)$ can also be defined as a partial function $t : N^* \rightarrow F \cup X$ with domain $\text{Pos}(t)$ satisfying the following properties:

(i) $\text{Pos}(t)$ is nonempty and prefix-closed;

(ii) For each $p \in \text{Pos}(t)$, if $t(p) \in F_n$, $n \geq 1$ then $\{i|pi \in \text{Pos}(t)\} = \{1, \ldots, n\}$;

(iii) For each $p \in \text{Pos}(t)$, if $t(p) \in X \cup F_0$ then $\{i|pi \in \text{Pos}(t)\} = \emptyset$.

The elements of $\text{Pos}(t)$ are called positions. A frontier position is a position $p$ such that $\forall \alpha \in N, \ \alpha \notin \text{Pos}(t)$. Each position $p$ in $t$ with $t(p) \in X$ is called a variable position and if $t(p) \in F_0$ it is called a constant position.

A subterm $t|_p$ of a term $t \in W_\tau(X)$ at position $p$ is defined as follows:

(i) $\text{Pos}(t|_p) = \{i|pi \in \text{Pos}(t)\}$;

(ii) $\forall j \in \text{Pos}(t|_p), \ t|_p(j) = t(pj)$.

The subtrees at the frontier positions for $t$ are called inputs of $t$.

By $t|_u[p]$ we denote the term obtained by replacing the subterm $t|_p$ in $t$ by $u$.

We write $\text{Head}(t) = f$ if and only if $t(\varepsilon) = f$, where $\varepsilon$ is the empty string in $N^*$, i.e. $f$ is the root symbol of $t$.

Thus we define a partial order relation in the set of all terms $W_\tau(X)$. We denote by $\preceq$ the subterm ordering, i.e. we write $t \preceq t'$ if there is a position $p$ for $t'$ such that $t = t'|_p$ and one says that $t$ is a subterm of $t'$. We write $t < t'$ if $t \preceq t'$ and $t \neq t'$.

A chain of subterms $Ch := t_{p_1} < t_{p_2} < \ldots < t_{p_k}$ is called strong if for all $j \in \{1, \ldots, k - 1\}$ there does not exist a term $s$ such that $t_{p_j} < s < t_{p_{j+1}}$.

3. Finite Tree Automata and Essential Variables

**Definition 2.** A finite tree automaton is a tuple $A = (Q, F, Q_f, \Delta)$ where:

- $Q$ is a finite set of states;
- $Q_f \subseteq Q$ is a set of final states;
- $\Delta$ is a set of transition rules i.e. if $F = F_0 \cup F_1 \cup \ldots \cup F_n$ then $\Delta = \{\Delta_0, \Delta_1, \ldots, \Delta_n\}$.
where \( \Delta_i \) are mappings \( \Delta_0 : F_0 \to Q \), and \( \Delta_i : F_i \times Q^i \to Q \), for \( i = 1, \ldots, n \).

We will suppose that \( A \) is complete i.e. the \( \Delta \)'s are total mappings on their domains. Let \( Y \subseteq X \) be a set of variables and \( \gamma : Y \to F_0 \) be a function which assigns nullary operation symbols (constants) to each input variable from \( Y \). The function \( \gamma \) is called assignment on the set of inputs \( Y \) and the set of such assignments will be denoted by \( \text{Ass}(Y, F_0) \).

Let \( t \in W_r(X) \), \( \gamma \in \text{Ass}(Y, F_0) \) and \( Y = \{ x_1, \ldots, x_m \} \). By \( \gamma(t) \) the term \( \gamma(t) = t(x_1 \leftarrow \gamma(x_1), \ldots, x_m \leftarrow \gamma(x_m)) \) will be denoted.

So, each assignment \( \gamma \in \text{Ass}(Y, F_0) \) can be extended to a mapping defined on the set \( W_r(X) \) of all terms.

Let \( t \in W_r(X) \), and \( \gamma \in \text{Ass}(X, F_0) \). The automaton \( A = \langle Q, F, Q_f, \Delta \rangle \) runs over \( t \) and \( \gamma \). It starts at leaves of \( t \) and moves downwards, associating along a run a resulting state with each subterm inductively:

(i) If \( \text{Depth}(t) = 0 \) then the automaton \( A \) associates with \( t \) the state \( q \in Q \), where

\[
q = \begin{cases} 
\Delta_0(\gamma(x_i)) & \text{if } t = x_i \in X; \\
\Delta_0(f_0) & \text{if } t = f_0 \in F_0.
\end{cases}
\]

(ii) Let \( \text{Depth}(t) \geq 1 \). If \( t = f(t_1, \ldots, t_n) \) and the states \( q_1, \ldots, q_n \) have been associated with the subterms(subtrees) \( t_1, \ldots, t_n \) then with \( t \) the automaton \( A \) associates the state \( q \), according to \( q = \Delta_n(f, q_1, \ldots, q_n) \).

The automaton runs only over ground terms and each assignment from \( \text{Ass}(X, F_0) \) transforms any tree as a ground term.

The initial states are the states associated with the leaves of the tree as for terms with depth equals to 0 i.e. as in the case (i).

A term \( t, t \in W_r(X) \) is accepted by a tree automaton \( A = \langle Q, F, Q_f, \Delta \rangle \) if there exists an assignment \( \gamma \) such that when running over \( t \) and \( \gamma \) the automaton \( A \) associates with \( t \) a final state \( q \in Q_f \).

When \( A \) associates the state \( q \) with a subterm \( s \), we will write \( A(\gamma, s) = q \).

Let \( t \in W_r(X) \) be a term and \( A \) be a tree automaton which accepts \( t \). In this case one says that \( A \) recognizes \( t \) or \( t \) is recognizable by \( A \). The set of all by \( A \) recognizable terms is called tree-language recognized by \( A \) and will be denoted by \( L(A) \).

**Definition 3.** Let \( t \in W_r(X) \) and let \( A \) be a tree automaton. An input variable \( x_i \in \text{Var}(t) \) is called essential for the pair \((t, A)\) if there exist two assignments \( \gamma_1, \gamma_2 \in \text{Ass}(X, F_0) \) such that

\[
\gamma_1(x_i) \neq \gamma_2(x_i), \quad \forall x_j \in X, j \neq i \quad \gamma_1(x_j) = \gamma_2(x_j)
\]

with \( A(\gamma_1, t) \neq A(\gamma_2, t) \) i.e. \( A \) stops in different states when running over \( t \) with \( \gamma_1 \) and with \( \gamma_2 \).

The set of all essential inputs for \((t, A)\) is denoted by \( \text{Ess}(t, A) \). The input variables from \( \text{Var}(t) \setminus \text{Ess}(t, A) \) are called fictive for \((t, A)\).

**Example 1.** Let \( A = \langle Q, F, Q_f, \Delta \rangle \) with

\[
F_0 = \{ 0, 1 \}, \quad F_1 = \{ f_1 \}, \quad F_2 = \{ g_1, g_2 \}, \quad Q = \{ q_0, q_1 \}, \quad Q_f = \{ q_1 \},
\]

\[
\Delta_0(0) = q_0, \quad \Delta_0(1) = q_1, \quad \Delta_1(f_1, q_0) = q_1, \quad \Delta_1(f_1, q_1) = q_0,
\]

\[
\Delta_2(g_1, q_0, q_1) = \Delta_2(g_1, q_1, q_0) = \Delta_2(q_0, q_1, q_1) = q_1, \quad \Delta_2(g_1, q_0, q_0) = q_0,
\]

\[
\Delta_2(g_2, q_0, q_0) = \Delta_2(g_2, q_0, q_1) = \Delta_2(q_2, q_1, q_1) = q_0, \quad \Delta_2(g_2, q_1, q_1) = q_1.
\]

Let us consider the term \( t = g_2(g_1(f_1(x_3), x_3), x_1) \).

The tree of the term \( t \) is given on the Figure[1]
The set of positions for $t$ is:
\[ \text{Pos}(t) = \{ \varepsilon, 1, 11, 111, 12, 2 \} \]
and the corresponding subterms to these positions are:
\[ t|_{1} = g_1(f_1(x_2), x_1), \ t|_{11} = f_1(x_2), \ t|_{12} = x_1, \ t|_{111} = x_2, \ t|_{2} = x_1. \]
There are four possible assignments and exactly three strong chains of subterms which connect the leaves of $t$ and the root of $t$.
It is easy to see that $x_2 \in \text{Ess}(t|_1, A)$, and $x_2 \in \text{Ess}(t|_{11}, A)$, but $x_2 \notin \text{Ess}(t, A)$.

When investigating the finite valued functions with respect to their essential variables and their subfunctions a remarkable result says that [2]: if a variable $x_i$ is essential for a subfunction $f_1$ of $f$ then there is a chain
\[ f_1 \prec f_2 \prec \cdots \prec f_n = f, \]
such that $x_i$ is essential for $f_j$, where $j = 1, 2, \ldots, n$ and $h \prec g$ means that $h$ is a subfunction of $g$.

This result for trees and automata is not held.

Consider the subtree $t|_1 = g_1(f_1(x_2), x_1)$ of the tree $t$ given in the Example [1]. It is easy to see that $x_2 \in \text{Ess}(t|_1, A)$ but $x_2 \notin \text{Ess}(t, A)$. In [10] the following theorem is proved.

**Theorem 1.** If $x_i \in \text{Ess}(t, A)$ then there exists a strong chain $x_i = t_1 \triangleleft t_2 \triangleleft \cdots \triangleleft t_k \subseteq t$ such that $x_i \in \text{Ess}(t_j, A)$ for $j = 1, \ldots, k$. $\blacksquare$

**Proposition 1.** $\forall \gamma \in \text{Ass}(X, F_0) \ A(\gamma, t') = A(\gamma, t)$ then $\text{Ess}(t, A) = \text{Ess}(t', A)$. 

\begin{figure}[h]
\centering
\includegraphics{figure1}
\caption{Figure 1.}
\end{figure}
Another important result for finite valued functions concerns strongly essential variables which we will prove for trees and automata, which is the aim of the next section.

4. STRONGLY ESSENTIAL INPUTS

Definition 4. Let $t \in W_f(X)$ and let $A$ be a tree automaton and $M \subseteq \text{Ess}(t, A)$ ($M \neq \emptyset$). An input variable $x_i \in M$ is called strongly essential for the pair $(t, A)$ with respect to set $M$ if there exist value $f_0$ for the input $x_i$ such that $M \setminus \{x_i\} \subseteq \text{Ess}(t(x_i \leftarrow f_0), A)$.

Lemma 1. Let $\text{Ess}(t, A) = Y_1 \cup Y_2$, $Y_1 \neq \emptyset$, $Y_1 \cap Y_2 = \emptyset$. If there is an assignment $\gamma \in \text{Ass}(Y_2, F_0)$ such that $Y_1 = \text{Ess}(\gamma(t), A)$ then there is an input $x_i \in Y_2$ which is strongly essential for $t$ with respect to $A$.

Proof. At first let $\text{Ess}(t, A) = \{x_1, x_2\}$. Clearly both $x_1$ and $x_2$ are strongly essential with $Y_1 = \{x_1\}$, and $Y_2 = \{x_2\}$.

Suppose that for each $s \in W_f(X)$ with $\text{Ess}(s, A) = Y_1 \cup Y_2$, $Y_1 \neq \emptyset$, $Y_1 \cap Y_2 = \emptyset$, $|Y_2| \leq l$ and there is an assignment $\gamma \in \text{Ass}(Y_2, F_0)$ such that $Y_1 = \text{Ess}(\gamma(s), A)$ then there exists a strongly essential input $x_i \in Y_2$ of $s$ with respect to $A$.

Let us consider a tree $t$ with $\text{Ess}(t, A) = Y_1 \cup Y_2$, $Y_1 \cap Y_2 = \emptyset$, $|Y_2| = l + 1$ and there is an assignment $\gamma \in \text{Ass}(Y_2, F_0)$ such that $Y_1 = \text{Ess}(\gamma(t), A)$. Let $Y_3 = \{x_{m+1}, \ldots, x_{m+l+1}\}$. Let $t_1 = t(x_{m+1} \leftarrow \gamma(x_{m+1}))$.

If $Y_2 \setminus \{x_{m+1}\} \subseteq \text{Ess}(t_1, A)$ then clearly $x_{m+1}$ is strongly essential input for $t$ with respect to $A$.

Consider the case $Y_2 \setminus \{x_{m+1}\} \not\subseteq \text{Ess}(t_1, A)$ and let $x_j \in (Y_2 \setminus \{x_{m+1}\}) \setminus (\text{Ess}(t_1, A))$. This means that for each $f_0 \in F_0$ and for each $\gamma_1 \in \text{Ass}(Y_2 \setminus \{x_{m+1}, x_j\})$ $A(\gamma_1, t_1) = A(\gamma_1, t_2)$ where $t_2 = t_1(x_j \leftarrow f_0)$. Let $f'_0$ be such that $x_{m+1} \in \text{Ess}(t_3, A)$ where $t_3 = t(x_j \leftarrow f'_0)$.

It is clear that

$$Y_1 \subseteq \text{Ess}(t_3, A).$$

Let us set $Y_3 = Y_2 \setminus \text{Ess}(t_3, A)$. Obviously $Y_3 \neq \emptyset$ (note that $x_j \in Y_3$). On the other hand $x_{m+1} \notin Y_3$ and $Y_3 \subset Y_2$. Clearly $|Y_3| \leq l$. Let us set $Y'_1 = Y_1 \cup (Y_2 \setminus Y_3)$ and $Y'_2 = Y_3$. By $Y_3 \cap \text{Ess}(t_3, A) = \emptyset$ and $\text{Ess}(t_3, A) = Y'_1$ it follows that there is at least one assignment $\gamma' \in \text{Ass}(Y'_2, F_0)$ such that

$$Y'_1 = \text{Ess}(\gamma', t).$$

By the inductive assumption it follows that there is an input $x_r \in Y'_3$ which is strongly essential input for $t$ with respect to $A$.

Theorem 2. Let $t \in W_f(X)$ and let $A$ be a tree automaton. If $|\text{Ess}(t, A)| \geq 2$ then there is at least one strongly essential input of $t$ with respect to $A$.

Proof. Let $\text{Ess}(t, A) = \{x_1, \ldots, x_n\}$. By $x_1 \in \text{Ess}(t, A)$ it follows that there is an assignment $\gamma \in (Y_2, F_0)$ with $Y_1 = \text{Ess}(\gamma(t), A)$ where $Y_1 = \{x_1\}$ and $Y_2 = \{x_2, \ldots, x_n\}$. From this the the lemma implies the proof of the theorem.

Corollary 1. Let $t \in W_f(X)$ and let $A$ be a tree automaton. If $|\text{Ess}(t, A)| \geq 2$ then there is at least two strongly essential input of $t$ with respect to $A$. 

5. Minimal Tree Automata

In this section we consider minimization algorithms for trees and automata. Proposition 1 shows that if $t_1 < t_2 < t$ and $\forall \gamma \in \text{Ass}(X, F_0) A(\gamma, t_1) = A(\gamma, t_2)$ then $A(\gamma, t) = A(\gamma', t')$ for all $\gamma' \in \text{Ass}(X, F_0)$ and

$$t' = t(t_2 \leftarrow t_1).$$

Clearly if $t_1$ is a proper subtree of $t_2$ then $t'$ is a tree obtained from $t$ with a reduction of the nodes i.e. $t'$ is more simple than $t$.

Another reduction can be obtained by removing of all non essential inputs of $t$.

These two operations (replacing $t_1$ and $t_2$ and removing the fictive inputs) are used to reach minimal trees w.r.t. an automaton $A$.

**Definition 5.** A tree $t$ and an automaton $A$ are minimal if there are not any operations for reduction of $t$.

Clearly, the algorithm to find out minimal tree, automaton consist of applying all possible reductions on the tree w.r.t. the automaton.

6. Applications

Tree automata were designed in the context of circuit verification and logic programming. Becoming an important part of theoretical basis of the computing and programming, tree automata have been used as powerful tools in program verification. In present computer technologies there are many examples where we can find the underlying tree automata.

**GUI**

Powerful and intelligent Graphical User Interface (GUI) interacting with menus, dialogs, icons, etc. have hierarchical structure. The interactions with an element of the GUI reflect on the whole GUI. Each object send messages to the parent object on any action. The process for message passing between GUI objects is organized as automaton working over tree.

**XML**

Databases as a concept for storing information is one of the major parts of the computer technology. Several main types of databases were affirmed. Now the dominating relational databases are going to be replaced by the well known hierarchical databases, using the XML technology. In the XML documents the nodes are divided in two types - nodes and attributes. The attributes are leaves and the nodes are the inner nodes of the tree. One to one mapping between XML document and tree exist. There are several manipulations with XML documents that the XML parser process as a Tree Automata, i.e. XSL translation, work with the DOM, validation with DTD.

**OOP**

In Object Oriented Languages such as C++ and Java, a user defined data type, a 'class', is introduced. Classes of objects can be put into hierarchy. Each class may contain fields that are variables or methods. Class fields may have different visibility. Again there is one to one mapping between class hierarchy and trees. One class can derive from another in different ways (using visibility modifiers) which reflect on the visibility of the inherited fields. During the syntax checking
of the program the translator works as a tree automata calculating the visibility of the class fields.
