Abstract

In this paper, the structural controllability of switched linear systems is investigated. In particular, switched linear systems with independent subsystem models are studied. The structural controllability is a generalization of the traditional controllability concept for dynamical systems, and purely based on the graphic topologies among state and input vertices. First, two kinds of graphic representations of switched linear systems are proposed. Second, graph theory based necessary and sufficient characterizations of the structural controllability for switched linear systems are presented. Finally, the paper concludes with one illustrative example and discussions on the results and future work.

Index Terms

Structural controllability, switched linear system, graphic interpretation.

I. INTRODUCTION

As a special class of hybrid control systems, a switched linear system consists of several linear subsystems and a rule that orchestrates the switching among them. Switching between different subsystems or different controllers can greatly enrich the control strategies and may accomplish certain control objective which can not be achieved by conventional dynamical systems. For example, it provided an effective mechanism to cope with highly complex systems

*Manuscript titled “Structural Controllability of Switched Linear Systems” is submitted to IEEE Transactions on Automatic Control, 2011
and/or systems with large uncertainties [1]. References [2] presented good examples that switched controllers could provide a performance improvement over a fixed controller. Besides, switched linear systems also have promising applications in control of mechanical systems, aircrafts, satellites and swarming robots. Driven by its importance in both theoretical research and practical applications, switched linear system has attracted considerable attention during the last decade [3]-[10].

Much work has been done on the controllability of switched linear systems. For example, the controllability and reachability for low-order switched linear systems have been presented in [4]. Under the assumption that the switching sequence is fixed, references [5][6] introduced some sufficient conditions and necessary conditions for controllability of switched linear systems. Complete geometric criteria for controllability and reachability were established in [7][9].

Up to now, all the previous work mentioned above has been based on the traditional controllability concept of switched linear systems. In this paper, we propose a new notion for the controllability of switched linear system: structural controllability, which may be more reasonable in face of uncertainties. Actually, it is more often than not that most of system parameter values are difficult to identify and only known to certain approximations. On the other hand, we are usually pretty sure where zero elements are either by coordination or by the absence of physical connections among components of the system. Thus structural properties that are independent of a specific value of unknown parameters, e.g., the structural controllability studied here, are of particular interest. It is therefore assumed here that all the elements of matrices of switched linear systems are fixed zeros or free parameters. Furthermore, the switched linear system is said to be structurally controllable if one can find a set of values for the free parameters such that the corresponding switched linear system is controllable in the classical sense. For linear structured systems, generic properties including structural controllability have been studied extensively and it turns out that generic properties including structural controllability are true for almost all values of the parameters [11]-[19]. That is also true for switched linear systems studied here and presents one of the reasons why this kind of structural controllability is of interest.

Graphic conditions can help to understand how the graphic topologies of dynamical systems influence the corresponding generic properties, here especially for the structural controllability. This would be helpful in many practical applications. For example, in multi-agent systems, graphic interpretations for structural controllability help us to understand the necessary informa-
tion exchange among agents to make the whole team well-behaved, e.g., controllable. Therefore, this motivates our pursuit on illuminating the structural controllability of switched linear systems from a graph theoretical point of view. In this paper, we propose two graphic representations of switched linear systems and finally, it turns out that the structural controllability of switched linear systems only depends on the graphic topologies of the corresponding systems.

The organization of this paper is as follows: In Section II, we introduce some basic preliminaries and the problem formulation, followed by structural controllability study of switched linear systems in Section III, where several graphic necessary and sufficient conditions for the structural controllability are given. One illustrative example together with discussions on a more general case are also presented. Finally, some concluding remarks are drawn in Section IV.

II. Preliminaries and Problem Formulation

A. Graph Theory Preliminaries

First of all, definition and example of a structured matrix are introduced as follows:

Definition 1: \( P \) is said to be a structured matrix if its entries are either fixed zeros or independent free parameters. \( \hat{P} \) is called admissible (with respect to \( P \)) if it can be obtained by fixing the free parameters of \( P \) at some particular values. In addition \( P_{ij} \) is adopted to represent the element of \( P \) from row \( i \) and column \( j \).

Example 1: \( P = \begin{bmatrix} 0 & \lambda_1 \\ \lambda_2 & \lambda_3 \end{bmatrix} \) is a structured matrix, where \( \lambda_1, \lambda_2 \) and \( \lambda_3 \) are free parameters, and \( \hat{P} = \begin{bmatrix} 0 & 1 \\ 2 & 0 \end{bmatrix} \) is admissible with respect to \( P \).

Now consider a linear control system:

\[
\dot{x} = Ax(t) + Bu(t),
\]

where \( x(t) \in \mathbb{R}^n \) and \( u(t) \in \mathbb{R}^r \). The matrices \( A \) and \( B \) are structured matrices, which means that their elements are either fixed zeros or free parameters. This structured system given by matrix pair \( (A, B) \) can be described by a directed graph \( G \):

Definition 2: The representation graph of structured system \( (A, B) \) is a directed graph \( G \), with vertex set \( \mathcal{V} = \mathcal{X} \cup \mathcal{U} \), where \( \mathcal{X} = \{x_1, x_2, \ldots, x_n\} \), which is called state vertex set and \( \mathcal{U} = \{u_1, u_2, \ldots, u_r\} \), which is called input vertex set, and edge set \( \mathcal{I} = \mathcal{I}_{UX} \cup \mathcal{I}_{XX} \), where

January 28, 2013

DRAFT
\[ I_{UX} = \{(u_i, x_j) | B_{ji} \neq 0, 1 \leq i \leq r, 1 \leq j \leq n \} \] and \[ I_{XX} = \{(x_i, x_j) | A_{ji} \neq 0, 1 \leq i \leq n, 1 \leq j \leq n \} \] are the oriented edges between inputs and states and between states defined by the interconnection matrices \( A \) and \( B \) above. This directed graph (for notational simplicity, we will use digraph to refer to directed graph) \( G \) is also called the graph of matrix pair \( (A, B) \) and denoted by \( G(A, B) \).

Note that the total number of vertices in \( G(A, B) \) equals to the summation of states number and inputs number. One important graphic definition is needed before we proceed forward:

**Definition 3:** (Stem [11]) An alternating sequence of distinct vertices and oriented edges is called a directed path, in which the terminal node of any edge never coincide to its initial node or the initial or the terminal nodes of the former edges. A stem is a directed path in the state vertex set \( \mathcal{X} \), that begins in the input vertex set \( \mathcal{U} \).

Two graphic properties ‘accessibility’ and ‘dilation’ were proposed by [11], which will serve as the basis of following discussion. We state them as follows:

**Definition 4:** (Accessibility [11]) A vertex (other than the input vertices) is called nonaccessible if and only if there is no possibility of reaching this vertex through any stem of the graph \( G \).

**Definition 5:** (Dilation [11]) Consider one vertex set \( S \) formed by the vertices from the state vertices set \( \mathcal{X} \) and determine another vertex set \( T(S) \), which contains all the vertices \( v \) with the property that there exists an oriented edge from \( v \) to one vertex in \( S \). Then the graph \( G \) contains a ‘dilation’ if and only if there exist at least a set \( S \) of \( k \) vertices in the vertex set of the graph such that there are no more than \( k - 1 \) vertices in \( T(S) \).

### B. Switched Linear System, Controllability and Structural Controllability

In general, a switched linear system is composed of a family of subsystems and a rule that governs the switching among them, and is mathematically described by

\[
\dot{x}(t) = A_{\sigma(t)}x(t) + B_{\sigma(t)}u(t),
\]

where \( x(t) \in \mathbb{R}^n \) are the states, \( u(t) \in \mathbb{R}^r \) are piecewise continuous input, \( \sigma : [0, \infty) \rightarrow M \triangleq \{1, \ldots, m\} \), where time slot 0 is system initial time, is the switching signal. System (2) contains \( m \) subsystems \((A_i, B_i)\), \( i \in \{1, \ldots, m\} \) and \( \sigma(t)= i \) implies that the \( i \)th subsystem \((A_i, B_i)\) is active at time instance \( t \).

In the sequel, the following definition of controllability of system (2) will be adopted (Definition 7 in [7]):
Definition 6: Switched linear system (2) is said to be (completely) controllable if for any initial state $x_0$ and final state $x_f$, there exist a time instance $t_f > 0$, a switching signal $\sigma : [0, t_f) \to M$ and an input $u : [0, t_f) \to \mathbb{R}^r$ such that $x(0) = x_0$ and $x(t_f) = x_f$.

For the controllability of switched linear systems, a well-known matrix rank condition was given in [8]:

Lemma 1: (8) If matrix:

$$
\begin{bmatrix}
B_1, B_2, \ldots, B_m, A_1 B_1, A_2 B_1, \ldots, A_m B_1, A_1 B_2, A_2 B_2, \ldots, A_m B_2, \ldots, A_1 B_m, A_2 B_m, \ldots, A_m B_m,
A_1^2 B_1, A_2 A_1 B_1, \ldots, A_m A_1 B_1, A_1 A_2 B_1, A_2^2 B_1, \ldots, A_m A_2 B_1, \ldots, A_1 A_m B_m, A_2 A_m B_m, \ldots, A_m^2 B_m,
\ldots,
A_1^{n-1} B_1, A_2 A_1^{n-2} B_1, \ldots, A_m A_1^{n-2} B_1, A_1 A_2 A_1^{n-3} B_1, A_2^2 A_1^{n-3} B_1, \ldots, A_m A_2 A_1^{n-3} B_1, \ldots, A_1 A_m^{n-2} B_m,
A_2 A_m^{n-2} B_m, \ldots, A_m^{n-1} B_m
\end{bmatrix}
$$

(3)

has full row rank $n$, then switched linear system (2) is controllable, and vice versa.

Remark 1: This matrix is called controllability matrix of switched linear system (2) and for simplicity, we will use $C(A_1, \ldots, A_m, B_1, \ldots, B_m)$ to represent it. If we use $\text{Im} P$ to represent the range space of arbitrary matrix $P$, actually, $\text{Im} C(A_1, \ldots, A_m, B_1, \ldots, B_m)$ is the controllable subspace of switched linear system (2) [7] [8]. The above lemma implies that system (2) is controllable if and only if $\text{Im} C(A_1, \ldots, A_m, B_1, \ldots, B_m) = \mathbb{R}^n$. Besides, controllable subspace can be expressed as $\langle A_1, \ldots, A_m | B_1, \ldots, B_m \rangle$, which is the smallest subspace containing $\text{Im} B_i$, $i = 1, \ldots, m$ and invariant under the transformations $A_1, \ldots, A_m$ [10].

In view of structural controllability, system (2) will be treated as structured switched linear system defined as:

Definition 7: For structured system (2), the elements of all the matrices $(A_1, B_1, \ldots, A_m, B_m)$ are either fixed zero or free parameters and free parameters in different subsystems $(A_i, B_i)$, $i \in M$ are independent. A numerically given matrices $(\tilde{A}_1, \tilde{B}_1, \ldots, \tilde{A}_m, \tilde{B}_m)$ is called an admissible numerical realization (with respect to $(A_1, B_1, \ldots, A_m, B_m)$) if it can be obtained by fixing all free parameter entries of $(A_1, B_1, \ldots, A_m, B_m)$ at some particular values.

Similar with the definition of structural controllability of linear system in [18], we have the following definition for structural controllability of switched linear system (2):

Definition 8: Switched linear system (2) given by its structured matrices $(A_1, B_1, \ldots, A_m, B_m)$ is said to be structurally controllable if and only if there exists at least one admissible realization
(\tilde{A}_1, \tilde{B}_1, \ldots, \tilde{A}_m, \tilde{B}_m) such that the corresponding switched linear system is controllable in the usual numerical sense.

Before proceeding further, we need to introduce the definition of $g$-rank of one matrix:

**Definition 9:** The generic rank ($g$-rank) of a structured matrix $P$ is defined to be the maximal rank that $P$ achieves as a function of its free parameters.

Then, we have the following algebraic condition for structural controllability of system (2):

**Lemma 2:** Switched linear system (2) is structurally controllable if and only if

\[ g\text{-rank } C(A_1, \ldots, A_m, B_1, \ldots, B_m) = n. \]

### III. Structural Controllability of Switched Linear Systems

#### A. Criteria Based on Union Graph

For switched linear system (2), let’s use $G_i$ with vertex set $V_i$ and edge set $I_i$ to represent the underlying graph of subsystem $(A_i, B_i), i \in \{1, \ldots, m\}$.

As to the whole switched system, one kind of representation graph, which is called union graph, is described in the following definition:

**Definition 10:** Switched linear system (2) can be represented by a union digraph $G$ (sometimes named union graph without leading to confusion). Mathematically, $G$ is defined as

\[ G_1 \cup G_2 \cup \ldots \cup G_m = \{ V_1 \cup V_2 \cup \ldots \cup V_m; I_1 \cup I_2 \cup \ldots \cup I_m \} \]

For the union graph $G$, the vertex set is the same as the vertex set of every subgraph $G_i$. The edge set of $G$ equals to the union of the edge sets of the subgraphs. Note that there are no multiple edges between any two vertices in $G$.

**Remark 2:** It turns out that union graph $G$ is the representation of linear structured system: $(A_1 + A_2 + \ldots + A_m, B_1 + B_2 + \ldots + B_m)$. The reason is that: If the element at position $a_{ji}(b_{ji})$ in $[A_1 + A_2 + \ldots + A_m, B_1 + B_2 + \ldots + B_m]$ is a free parameter, this implies that there exist some matrices $[A_p, B_p], p = 1, \ldots, m$ such that the element at position $a_{ji}(b_{ji})$ is also a free parameter and in the corresponding subgraph $G_p$, there is an edge from vertex $i$ to vertex $j$. According to the definition of union graph, it follows that there is also an edge from vertex $i$ to vertex $j$ in union graph $G$. If the element at position $a_{ji}(b_{ji})$ in $[A_1 + A_2 + \ldots + A_m, B_1 + B_2 + \ldots + A_m]$ is zero, this implies that for every matrices $[A_p, B_p], p = 1, \ldots, m$, the element at position $a_{ji}(b_{ji})$ is zero.
and in the corresponding subgraph $G_p$, there is no edge from vertex $i$ to vertex $j$. It follows that there is also no edge in union graph $G$ from vertex $i$ to vertex $j$.

Before proceeding further, we need to introduce two definitions which were proposed in [11] for linear system (11) first:

**Definition 11:** (11) The matrix pair $(A, B)$ is said to be reducible or of form I if there exists a permutation matrix $P$ such that they can be written in the following form:

\[
PAP^{-1} = \begin{bmatrix} A_{11} & 0 \\ A_{21} & A_{22} \end{bmatrix}, \quad PB = \begin{bmatrix} 0 \\ B_{22} \end{bmatrix}, \tag{4}\]

where $A_{11} \in \mathbb{R}^{p \times p}$, $A_{21} \in \mathbb{R}^{(n-p) \times p}$, $A_{22} \in \mathbb{R}^{(n-p) \times (n-p)}$ and $B_{22} \in \mathbb{R}^{(n-p) \times r}$.

**Remark 3:** Whenever the matrix pair $(A, B)$ is of form I, the system is structurally uncontrollable [11] and meanwhile, the controllability matrix $C \triangleq [B, AB, \ldots, A^{n-1}B]$ will have at least one row which is identically zero for all parameter values [14]. If there is no such permutation matrix $P$, we say that the matrix pair $(A, B)$ is irreducible.

**Definition 12:** (11) The matrix pair $(A, B)$ is said to be of form II if there exists a permutation matrix $P$ such that they can be written in the following form:

\[
\begin{bmatrix} PAP^{-1}, PB \end{bmatrix} = \begin{bmatrix} P_1 \\ P_2 \end{bmatrix}, \tag{5}\]

where $P_2 \in \mathbb{R}^{(n-k) \times (n+r)}$, $P_1 \in \mathbb{R}^{k \times (n+r)}$ with no more than $k-1$ nonzero columns (all the other columns of $P_1$ have only fixed zero entries).

The following lemma, which will underpin the following analysis on switched linear systems, details the criteria for evaluating structural controllability of linear system $(A, B)$ [11]-[18]:

**Lemma 3:** (11)-[18] For a linear system $(A, B)$, the following statements are equivalent:

a) the pair $(A, B)$ is structurally controllable;

b) i) $(A, B)$ is irreducible or not of form I,

ii) $(A, B)$ has $g$-rank$(A, B) = n$ or is not of form II;

c) i) there is no nonaccessible vertex in $G(A, B)$,

ii) there is no ‘dilation’ in $G(A, B)$.

This lemma proposed interesting graphic conditions for structural controllability of linear systems and revealed that the structural controllability is totally determined by the underlying
graph topology. However, for switched linear systems, to the best of our knowledge, proper graphic representations which can determine the structural controllability properties of switched linear systems are still lacking in the literature.

With the previous lemmas and definitions, we are in the position to present the first main result of the paper, which is actually a graphic sufficient condition for structural controllability of switched linear systems:

**Theorem 1:** Switched linear system (2) with graphic topologies $G_i$, $i \in \{1, \ldots, m\}$, is structurally controllable if its union graph $G$ satisfies:

i) there is no nonaccessible vertex in $G$,

ii) there is no ‘dilation’ in $G$.

**Proof:** Assume the two conditions in this theorem are satisfied. According to remark 2 and lemma 3, the corresponding linear system $(A_1 + A_2 + \ldots + A_m, B_1 + B_2 + \ldots + B_m)$ is structurally controllable. It follows that there exist some scalars for the free parameters in matrices $(A_i, B_i), i = 1, 2, \ldots, m$ such that controllability matrix

$$[B_1 + B_2 + \ldots + B_m, (A_1 + A_2 + \ldots + A_m)(B_1 + B_2 + \ldots + B_m),$$

$$(A_1 + A_2 + \ldots + A_m)^2(B_1 + B_2 + \ldots + B_m), \ldots, (A_1 + A_2 + \ldots + A_m)^{n-1}(B_1 + B_2 + \ldots + B_m)]$$

has full row rank $n$. Expanding the matrix, it follows that matrix

$$[B_1 + B_2 + \ldots + B_m, A_1B_1 + A_2B_1 + \ldots + A_mB_1 + A_1B_2 + A_2B_2$$

$$+ \ldots + A_mB_2 + \ldots + A_1B_m + A_2B_m \ldots + A_mB_m, \ldots, A_1^{n-1}B_1 + A_2A_1^{n-2}B_1 + \ldots + A_m^{n-1}B_m]$$

has full rank $n$.

The following matrix can be got after adding some column vectors to the above matrix:

$$[B_1 + B_2 + \ldots + B_m, B_2, \ldots, B_m, A_1B_1 + A_2B_1 + \ldots + A_mB_1 + A_1B_2 + A_2B_2$$

$$+ \ldots + A_mB_2 + \ldots + A_1B_m + A_2B_m + \ldots + A_mB_m, A_1B_1, \ldots, A_mB_m, \ldots,$$

$$A_1^{n-1}B_1 + A_2A_1^{n-2}B_1 + \ldots + A_1A_m^{n-2}B_1 + \ldots + A_m^{n-1}B_m, A_2A_1^{n-2}B_1, \ldots, A_1A_m^{n-2}B_1, \ldots, A_m^{n-1}B_m].$$

Since this matrix still has $n$ linear independent column vectors, it follows that it has full row rank $n$. Next, subtracting $B_2, \ldots, B_m$ from $B_1 + B_2 + \ldots + B_m$; subtracting $A_2B_1, \ldots, A_mB_m$ from $A_1B_1 + A_2B_1 + \ldots + A_mB_1 + \ldots + A_mB_m$ and subtracting $A_2A_1^{n-2}B_1, \ldots, A_1A_m^{n-2}B_1, \ldots, A_m^{n-1}B_m$.
from $A_1^{n-1}B_1 + A_2A_1^{n-2}B_1 + \ldots + A_1A_m^{n-2}B_1 + \ldots + A_m^{n-1}B_m$, we can get the following matrix:

$$[B_1, B_2, \ldots, B_m, A_1B_1, A_2B_1, \ldots, A_mB_m, \ldots, A_1^{n-1}B_1, A_2A_1^{n-2}B_1, \ldots, A_1A_m^{n-2}B_1, \ldots, A_m^{n-1}B_m],$$

which is the controllability matrix for switched linear systems (2). Since column fundamental transformation does not change the matrix rank, this matrix still has full row rank $n$. Hence, the switched linear system (2) is structurally controllable.

Actually, from the proof, we can see that full rank of controllability matrix of linear system $(A_1 + A_2 + \ldots + A_m, B_1 + B_2 + \ldots + B_m)$ in Remark 2 implies the full rank of controllability matrix of system (2), which means that the structural controllability of this linear system implies structural controllability of system (2). It turns out that this criterion is not necessary for system (2) to be structurally controllable (see the example in subsection C). This implies that the union graph does not contain enough information for determining structural controllability. This is because edges from different subsystems are not differentiated in union graph. In the following subsection, another graphic representation of switched linear systems is proposed, from which necessary and sufficient conditions for structural controllability arise.

B. Criteria Based on Colored Union Graph

Another graphic representation: ‘colored union graph’ is defined as follows:

**Definition 13:** Switched linear system (2) can be represented by a colored union digraph $\tilde{G}(\tilde{V}, \tilde{I})$ (sometimes named colored union graph without leading to confusion), where vertex set $\tilde{V} = \{V_1 \cup V_2 \cup \ldots \cup V_m\}$ and edge set $\tilde{I} = \{e | e \in I_i, i = 1, 2, \ldots, m\}$, i.e., for $i \in \{1, \ldots, m\}$, to each edge $e$ we associate index $i$ in $\tilde{G}$, if this edge is associated to the subsystem $i$ (subgraph $G_i$). Note that we associate several indexes (several different colors) to an edge $e$ if it belongs to several subsystems.

With this colored union graph, several graphic properties are introduced in the following lemmas.

**Lemma 4:** There is no nonaccessible vertex in the colored union graph $\tilde{G}$ of switched linear system (2) if and only if the matrix

$$[A_1 + A_2 + \cdots + A_m, B_1 + B_2 + \cdots + B_m]$$

is irreducible or not of form I.
**Proof:** One vertex is accessible if and only if it can be reached by a stem. From definitions 10 and 13, it follows that there is no nonaccessible vertex in the colored union graph if and only if there is no nonaccessible vertex in the union graph. Besides, from remark 2, it is clear that the matrix representation of the union graph is 
\[ A_1 + A_2 + \cdots + A_m, B_1 + B_2 + \cdots + B_m. \]
According to lemma 5 there is no nonaccessible vertex in the union graph if and only if matrix (6) is irreducible or not of form I. Consequently the equivalence between accessibility of colored union graph and irreducibility of matrix (6) gets proved.

A new graphic property ‘S-dilation’ in colored union graph needs to be introduced here:

**Definition 14:** In colored union graph \( \tilde{G} \), which is composed of subgraphs \( G_i, i = 1, 2, \ldots, m \), consider one vertex set \( S \) formed by the vertices from the state vertex set \( X \) and determine another vertex set \( T(S) = \{ v | v \in T_i(S), i = 1, 2, \ldots, m \} \), where \( T_i(S) \) is a vertex set in \( G_i \) which contains all the vertices \( w \) with the property that there exists an oriented edge from \( w \) to one vertex in \( S \). Then \( |T(S)| = \sum_{i=1}^m |T_i(S)| \). If \( |T(S)| < |S| \), we say that there is a S-dilation in the colored union graph \( \tilde{G} \).

Based on this new graphic property, the following lemma can be given:

**Lemma 5:** There is S-dilation in the colored union graph \( \tilde{G} \) of switched linear system (2) if and only if matrix \([A_1,A_2,\ldots,A_m,B_1,B_2,\ldots,B_m]\) is of form II. It means that this matrix can be written into: 
\[
\begin{bmatrix}
P_1 \\
P_2
\end{bmatrix}
\]
where \( P_1 \in \mathbb{R}^{p \times k} \) with no more than \( p - 1 \) nonzero columns (all the other columns of \( P_1 \) have only fixed zero entries).

**Proof:** From [11] [12] or lemma 3, it is known that in linear systems, there is no ‘dilation’ in the corresponding graph if and only if the matrix pair \([A,B]\) can not be of form II or have g-rank \( n \). From the explanation of this result in [11] and definition [12], \( P_1 \) in \([A,B]\) has \( p \) rows, which actually represents the \( p \) vertices of vertex set \( S \) (defined for dilation), and each nonzero element of each row of \( P_1 \) represents that there is one vertex pointing to the vertex presented by this row. Therefore, the number of nonzero columns in \( P_1 \) is the number of vertices pointing to some vertex in \( S \), and actually equals to \(|T(S)|\). Furthermore, by the definition of S-dilation, \(|T(S)|\) is now the summation of \(|T_i(S)|\), \( i \in \{1, \ldots, m\} \), in every subgraph. Consequently, it follows that there is S-dilation in the colored union graph \( \tilde{G} \) if and only if matrix \([A_1,A_2,\ldots,A_m,B_1,B_2,\ldots,B_m]\) in of form II.
Before going further to give another algebraic explanation of \textit{S-dilation}, one definition and lemma proposed in \cite{13} must be introduced first:

\textbf{Definition 15} \cite{13}: A structured $n \times m'$ ($n \leq m'$) matrix $A$ is of form $(t)$ for some $t$, $1 \leq t \leq n$, if for some $k$ in the range $m' - t < k \leq m'$, $A$ contains a zero submatrix of order $(n + m' - t - k + 1) \times k$.

\textbf{Lemma 6} \cite{13}: $g$-rank of $A = t$

i) for $t = n$ if and only if $A$ is not of form $(n)$;

ii) for $1 \leq t < n$ if and only if $A$ is of form $(t + 1)$ but not of form $(t)$.

From the above definition and lemma, another lemma is proposed here:

\textbf{Lemma 7}: There is no \textit{S-dilation} in the colored union graph $\tilde{G}$ of switched linear system \cite{2} if and only if the following matrix

\begin{equation}
[A_1, A_2, \ldots, A_m, B_1, B_2, \ldots, B_m] \tag{7}
\end{equation}

has $g$-rank $n$.

\textbf{Proof}: \textit{Necessity}: If matrix \eqref{7} has $g$-rank $< n$, from lemma \ref{6} it follows that matrix \eqref{7} is of form $(n)$. Then referring to definition \ref{15} matrix \eqref{7} must have a zero submatrix of order $(n + m' - t - k + 1) \times k$. Here, $t$ can be chosen as $n$, then \eqref{7} has a zero submatrix of order $(m' - k + 1) \times k$. For this $(m' - k + 1)$ rows, there are only $(m' - k)$ nonzero columns. Consequently, matrix \eqref{7} is of form II and by lemma \ref{5} there is \textit{S-dilation} in the colored union graph $\tilde{G}$ of switched linear system \cite{2}.

\textit{Sufficiency}: If there is \textit{S-dilation} in the colored union graph $\tilde{G}$, by lemma \ref{5} matrix \eqref{7} is of form II, then obviously $P_1$ in \eqref{7} can not have row rank equal to $k$ and furthermore, matrix \eqref{7} can not have $g$-rank $= n$.

With the above definitions and lemmas, a graphic necessary and sufficient condition for switched linear system to be structurally controllable can be proposed here:

\textbf{Theorem 2}: Switched linear system \cite{2} with graphic representations $\mathcal{G}_i$, $i \in \{1, \ldots, m\}$, is structurally controllable if and only if its colored union graph $\tilde{\mathcal{G}}$ satisfies the following two conditions:

i) there is no nonaccessible vertex in the colored union graph $\tilde{\mathcal{G}}$,

ii) there is no \textit{S-dilation} in the colored union graph $\tilde{\mathcal{G}}$.

\textbf{Proof}: \textit{Necessity}: (i) If there exist nonaccessible vertices in $\tilde{\mathcal{G}}$, by Lemma \ref{4} the matrix $[A_1 + A_2 + \cdots + A_m, B_1 + B_2 + \cdots + B_m]$ is reducible or of form I. It follows that the controllability
matrix

\[
[B_1 + B_2 + \ldots + B_m, (A_1 + A_2 + \ldots + A_m)(B_1 + B_2 + \ldots + B_m)],
\]

\[
(A_1 + A_2 + \ldots + A_m)^2(B_1 + B_2 + \ldots + B_m), \ldots, (A_1 + A_2 + \ldots + A_m)^{n-1}(B_1 + B_2 + \ldots + B_m)]
\]
always has at least one row that is identically zero (remark 3). It is clear that every component
of the matrix, such as \(B_iA_iB_j\) and \(A_i^pA_j^qB_r\), has the same row always to be zero. As a result, the
controllability matrix

\[
[B_1, \ldots, B_m, A_1B_1, \ldots, A_mB_m, A_1^2B_1, \ldots, A_mA_1B_1, \ldots, A_1^2B_m, \ldots, A_mA_1B_m, \ldots,
\]

\[
A_1^{n-1}B_1, \ldots, A_mA_1^{n-2}B_1, \ldots, A_1A_1^{n-2}B_m, \ldots, A_m^{n-1}B_m
\]
to always has one zero row and can not be of full rank \(n\). Therefore, switched linear system (2) is
not structurally controllable.

(ii) Suppose that the switched linear system (2) is structurally controllable, i.e., the controllability
matrix satisfies \(g\)-rank \(C(A_1, \ldots, A_m, B_1, \ldots, B_m) = n\). Specifically, \(\text{Im}[B_1, \ldots, B_m, A_1B_1, \ldots,
A_mB_m, A_1^2B_1, \ldots, A_m^{n-1}B_m] = \mathbb{R}^n\). Since \(\forall P \in \mathbb{R}^{nxr}\), \(\text{Im}(A_1P) \subseteq \text{Im}(A_1)\), we have that \(\text{Im}[B_1, \ldots, B_m, A_1B_1, \ldots, A_mB_m, A_1^2B_1, \ldots, A_m^{n-1}B_m] \subseteq \text{Im}[A_1, A_2, \ldots, A_m, B_1, B_2, \ldots, B_m] \subseteq \mathbb{R}^n\). Thus \(g\)-rank \(C(A_1, \ldots, A_m, B_1, \ldots, B_m) = n\) requires that \(\text{Im}[A_1, A_2, \ldots, A_m, B_1, B_2, \ldots, B_m] = \mathbb{R}^n\) and therefore \(g\)-rank
\([A_1, A_2, \ldots, A_m, B_1, B_2, \ldots, B_m] = n\). However, if there is \(S\)-dilation in the colored union graph \(\mathcal{G}\), by Lemma 3 \(g\)-rank \([A_1, A_2, \ldots, A_m, B_1, B_2, \ldots, B_m] < n\). Consequently, the switched linear system (2) is not structurally controllable.

 Sufficiency: The general idea in the sufficiency proof is that we will assume that the two
graphical conditions in the theorem hold. Then a contradiction will be found such that it is
impossible that switched linear system (2) is structurally uncontrollable.

Before proceeding to the switched linear system (2), firstly, consider a structured linear system:

\[
\dot{x}(t) = Ax(t) + Bu(t)
\]  

(8)
It is well known that system (8) is structurally controllable if and only if there exists a numerical
realization \((\tilde{A}, \tilde{B})\), such that \(\text{rank } (sI - \tilde{A}, \tilde{B}) = n, \forall s \in \mathbb{C}\). Otherwise, the PBH test [20] states
that system (8) is uncontrollable if and only if for every numerical realization, there exists a row
vector \(q \neq 0\) such that \(q\tilde{A} = s_0q, s_0 \in \mathbb{C}\) and \(q\tilde{B} = 0\), where \(\text{rank } (s_0I - \tilde{A}, \tilde{B}) < n\).

On one hand, if for every numerical realization \(\text{rank } (sI - \tilde{A}, \tilde{B}) = n, \forall s \in \mathbb{C} \setminus \{0\}\), then
the uncontrollability of system (8) implies necessarily that for every numerical realization there
exists a vector \(q \neq 0\) such that \(q\tilde{A} = 0\) and \(q\tilde{B} = 0\).
On the other hand, Lemma 14.1 of [18] states that, if in the digraph associated to (8), every state vertex is an end vertex of a stem (accessible), then \( g \)-rank \((sI - A, B) = n, \forall s \in \mathbb{C} \setminus \{0\}\), which means that for almost all numerical realization \((\tilde{A}, \tilde{B})\), rank \((sI - \tilde{A}, \tilde{B}) = n, \forall s \in \mathbb{C} \setminus \{0\}\).

Now considering the switched linear system (2), assume that the two conditions in Theorem 2 are satisfied. Due to Lemma 14.1 of [18], as all the parameters of matrices \(A_1, \ldots, A_m, B_1, \ldots, B_m\) are assumed to be free, the condition (i) of Theorem 2 implies that, for almost all vector values \(\tilde{u} = (\tilde{u}_1, \ldots, \tilde{u}_m)\), we have \(g\)-rank \((sI - (\tilde{u}_1A_1 + \ldots + \tilde{u}_mA_m), (\tilde{u}_1B_1 + \ldots + \tilde{u}_mB_m)) = n, \forall s \neq 0\). On the other hand, if the switched linear system (2) is structurally uncontrollable, then for all constant values, \(\tilde{u} = (\tilde{u}_1, \ldots, \tilde{u}_m)\), linear systems defined by matrices \((\tilde{A}, \tilde{B})\) are also uncontrollable, where \(\tilde{A} = \sum_{i=1}^m \tilde{u}_iA_i\) and \(\tilde{B} = \sum_{i=1}^m \tilde{u}_iB_i\). We write the numerical realization of \((\tilde{A}, \tilde{B})\) as \((\tilde{\tilde{A}}, \tilde{\tilde{B}})\). This is due to the fact that for all constant values \(\tilde{u}\), \(\text{Im}(C(\tilde{A}, \tilde{B}) \subseteq \text{Im}(C(A_1, \ldots, A_m, B_1, \ldots, B_m))\). Therefore, if the switched linear system is structurally uncontrollable, since for almost all \(\tilde{u} = (\tilde{u}_1, \ldots, \tilde{u}_m)\), \(g\)-rank \((sI - (\tilde{u}_1A_1 + \ldots + \tilde{u}_mA_m), (\tilde{u}_1B_1 + \ldots + \tilde{u}_mB_m)) = n, \forall s \neq 0\), we have that for every numerical realization matrix pair \((\tilde{\tilde{A}}, \tilde{\tilde{B}})\), there exists a nonzero vector \(q\) such that \(q\tilde{A} = 0\) and \(q\tilde{B} = 0\). Since this statement is true for almost all the values \(\tilde{u} = (\tilde{u}_1, \ldots, \tilde{u}_m)\), we have that for almost all \(n \cdot m\)-tuple values \(\tilde{u}^j = (\tilde{u}_1^j, \ldots, \tilde{u}_m^j), j = 1, \ldots, n \cdot m\), we can find nonzero vectors \(q_j\) such that the following holds:

\[
\begin{align*}
\sum_{i=1}^m \tilde{u}_i^j q_j \tilde{A}_i & = 0, \quad j = 1, \ldots, n \cdot m \\
\sum_{i=1}^m \tilde{u}_i^j q_j \tilde{B}_i & = 0, \quad j = 1, \ldots, n \cdot m 
\end{align*}
\]

(9)

Obviously, there can not exist more than \(n\) linear independent vectors \(q_j\). Let us denote \(q_1, q_2, \ldots, q_n\) the vectors such that \(\text{span} (q_1, q_2, \ldots, q_{n-m}) \subseteq \text{span} (q_1, q_2, \ldots, q_n)\) (we can renumber the vectors if necessary). All the vectors \(q_j, j = n + 1, \ldots, n \cdot m\) are linear combinations of \(q_1, q_2, \ldots, q_n\). Therefore, system (9) contains the following equations:

\[
\begin{align*}
\sum_{k=1}^n \sum_{i=1}^m a_{ik}^j (\tilde{u}) q_k \tilde{A}_i & = 0 \quad j = 1, \ldots, n \cdot m \\
\sum_{k=1}^n \sum_{i=1}^m a_{ik}^j (\tilde{u}) q_k \tilde{B}_i & = 0 \quad j = 1, \ldots, n \cdot m 
\end{align*}
\]

(10)
where \( d_{ik}^{j}(\bar{u}) \) are linear functions of \( \bar{u}^j, j = 1, \ldots, n \cdot m \). Since system (9) is satisfied for almost all the values, we can find \( \bar{u}^j, j = 1, \ldots, n \cdot m \) such that

\[
\begin{vmatrix}
  a_{1,1}^{1}(\bar{u}) & a_{1,2}^{1}(\bar{u}) & \cdots & a_{m,n}^{1}(\bar{u}) \\
  a_{1,1}^{2}(\bar{u}) & a_{1,2}^{2}(\bar{u}) & \cdots & a_{m,n}^{2}(\bar{u}) \\
  \cdots & \cdots & \cdots & \cdots \\
  a_{1,1}^{n-m}(\bar{u}) & a_{1,2}^{n-m}(\bar{u}) & \cdots & a_{m,n}^{n-m}(\bar{u})
\end{vmatrix} \neq 0.
\]

In this case, the only solution of (10) is \( q_k \bar{A}_1 = \ldots = q_k \bar{A}_m = q_k \bar{B}_1 = \cdots = q_k \bar{B}_m = 0, k = 1, \ldots, n \). Obviously, if the switched linear system is structurally uncontrollable, then vector \( q_k, k = 1, \ldots, n \) is nonzero. Consequently, the switched linear system (2) is structurally uncontrollable only if for every numerical realization there exists at least one nonzero vector \( q \) such that \( qA_1 = \ldots = qA_m = qB_1 = \cdots = qB_m = 0 \). However, if condition ii of Theorem 2 is satisfied, then \( g\text{-rank} [A_1, \ldots, A_m, B_1, \ldots, B_m] = n \) and therefore, for at least one numerical realization, there does not exist a vector \( q \neq 0 \) such that \( qA_1 = \ldots = qA_m = qB_1 = \cdots = qB_m = 0 \). Hence, the two conditions are sufficient to ensure the structural controllability of switched linear system (2).

Actually, using the terminologies ‘dilation’ and ‘\( S \)-dilation’ as graphic criteria is not so numerically efficient. For example, to check the second condition of Theorem 2 we need to test for all possible vertex subsets to see whether there exist \( S \)-dilation in the colored union graph or not. Consequently, we will adopt another notion ‘\( S \)-disjoint edges’ to form a more numerically efficient graphic interpretation of structural controllability.

**Definition 16:** In the colored union graph \( \tilde{G} \), consider \( k \) edges \( e_1 = (v_1, v'_1), e_2 = (v_2, v'_2), \ldots, e_k = (v_k, v'_k) \). We define for \( i = 1, \ldots, k \), \( S_i \) as the set of integers \( j \) such that \( v_j = v_i \), i.e., \( S_i = \{ 1 \leq j \leq k | v_j = v_i \} \). \( e_1, e_2, \ldots, e_k \) are \( S \)-disjoint if the following two conditions are satisfied:

i) edges \( e_1, e_2, \ldots, e_k \) have distinct end vertices,

ii) for \( i = 1, \ldots, k \), \( S_i = \{ i \} \) or there exist \( r \) distinct integers \( i_1, i_2, \ldots, i_r \) such that \( e_{j_1} \in \mathcal{I}_{i_1}, e_{j_2} \in \mathcal{I}_{i_2}, \ldots, e_{j_r} \in \mathcal{I}_{i_r} \), where \( j_1, j_2, \ldots, j_r \) are all the elements of \( S_j \).

Roughly speaking, \( k \) edges are \( S \)-disjoint if their end vertices are all distinct and if all the edges which have the same begin vertex can be associated to distinct indexes \( i \). For this new graphic property, the following lemma can be given:

**Lemma 8:** Considering switched linear system (2), there exist \( n \) \( S \)-disjoint edges in associated colored union graph \( \tilde{G} \) if and only if \( [A_1, A_2, \ldots, A_m, B_1, B_2, \ldots, B_m] \) has \( g\text{-rank} = n \).
Proof: Necessity: If there exist $n$ $S$-disjoint edges in $\tilde{G}$, matrix $[A_1, A_2, \ldots, A_m, B_1, B_2, \ldots, B_m]$ contains at least $n$ free parameters. Since the $n$ $S$-disjoint edges have distinct end vertices, the corresponding $n$ free parameters lie on $n$ different rows. Besides, the $n$ $S$-disjoint edges have distinct begin vertices or have same begin vertex that can be associated to distinct indexes $i$. This implies that these $n$ free parameters lie on $n$ different columns. Keep these $n$ free parameters and set all the other free parameters to be zero. We can see that matrix $[A_1, A_2, \ldots, A_m, B_1, B_2, \ldots, B_m]$ has the following form:

\[
\begin{bmatrix}
0 & \lambda_1 & 0 & 0 & \ldots & 0 \\
0 & 0 & 0 & \lambda_2 & \ldots & 0 \\
\vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\
\lambda_n & 0 & 0 & 0 & \ldots & 0
\end{bmatrix},
\]

which has $g$-rank $n$.

Sufficiency: From the definition 12.3 and the following discussions of [18], for a structured matrix $Q$, $g$-rank $Q = s$-rank $Q$, where $s$-rank of $Q$ is defined as the maximal number of free parameters that no two of which lie on the same row or column. If matrix $[A_1, A_2, \ldots, A_m, B_1, B_2, \ldots, B_m]$ has $g$-rank $n$, it follows that there exists $n$ free parameters from $n$ different rows, which implies that the corresponding $n$ edges have different end vertices, from $n$ different columns, which implies that these $n$ edges start from different vertices or start from same vertices but can be associated to different indexes. Hence the condition that the matrix has $g$-rank $n$ is sufficient to ensure the existence of $n$ $S$-disjoint edges.

We can get another necessary and sufficient condition for structural controllability of system (2).

**Theorem 3:** Switched linear system (2) with graphic representations $\mathcal{G}_i$, $i \in \{1, \ldots, m\}$, is structurally controllable if and only if its colored union graph $\tilde{G}$ satisfies the following two conditions:

i) there is no nonaccessible vertex in the colored union graph $\tilde{G}$,

ii) there exist $n$ $S$-disjoint edges in the colored union graph $\tilde{G}$.

**Proof:** Lemma 5 and Lemma 8 show that there exist $n$ $S$-disjoint edges in the colored union graph $\tilde{G}$ if and only if there is no $S$-dilation in $\tilde{G}$. Then this theorem follows immediately.

**Remark 4:** Compared with condition using ‘$S$-dilation’, this condition using ‘$S$-disjoint edges’ does not require to check all the vertex subsets, which is a more efficient criterion. The maximal number of ‘$S$-disjoint edges’ can be calculated using bipartite graphs. For example, we can use...
the algorithm in [21], which allows to compute the cardinality of maximum matching into a bipartite graph. A bipartite graph is a graph whose vertices can be divided into two disjoint sets $\mathcal{U}$ and $\mathcal{W}$ such that every edge connects a vertex in $\mathcal{U}$ to one in $\mathcal{W}$. To build a bipartite graph in directed subgraph $\mathcal{G}_i(\mathcal{V}_i, I_i)$, what we need to do is adding some vertices and make $\mathcal{U}_i = \{v \in \mathcal{V}_i | \exists (v, v') \in I_i \}$, which implies that cardinality $|\mathcal{U}_i|$ equals to the number of nonzero columns in matrix $[A_i, B_i]$. Besides, $\mathcal{W}_i = \mathcal{X}_i$, i.e., the state vertex set. Then it follows that the maximum matching in this bipartite graph is the same as the maximal $S$-disjoint edge set in $\mathcal{G}_i(\mathcal{V}_i, I_i)$. According to definition of $S$-disjoint edges, the beginning vertex from different subgraphs should be differentiated when building the bipartite graph for colored union graph $\tilde{\mathcal{G}}$. Therefore for the bipartite graph of $\tilde{\mathcal{G}}$, $\mathcal{U} = \{v | \exists \mathcal{V}_i, v' \in I_i, i = 1, 2, \ldots, m\}$, which implies that cardinality $|\mathcal{U}|$ equals to the number of nonzero columns in matrix $[A_1, A_2, \ldots, A_m, B_1, B_2, \ldots, B_m]$. And $\mathcal{W} = \mathcal{X}$, i.e., the state vertex set. Similarly, the maximum matching in this bipartite graph is the same as the maximal $S$-disjoint edge set in colored union graph. Therefore the complexity order of algorithm using method in [21] is $O(\sqrt{\rho + n} \cdot q)$, where $q$ is the number of edges in colored union graph, i.e., the number of free parameters in all system matrices, $\rho$ is the number of nonzero columns in matrix $[A_1, A_2, \ldots, A_m, B_1, B_2, \ldots, B_m]$ and $n$ is number of state variables. Compared with condition (ii), condition (i) is easier to check. We have to look for paths which connect each state vertex with one of the input vertex. This is a standard task of algorithmic graph theory. For example, depth-first search or breadth-first search algorithm for traversing a graph can be adopted and the complexity order is $O(|V| + |E|)$, where $|V|$ and $|E|$ are cardinalities of vertex set and edge set in union graph.

C. Numerical Example

Consider a switched linear system with two subsystems as depicted by the graphic topologies in Fig. 1(a)-(b). In colored union graph $\tilde{\mathcal{G}}$ (Fig. 1(d)), thin lines represent edges from subgraph (a) and thick lines represent the edges from subgraph (b). It turns out that the colored union graph $\tilde{\mathcal{G}}$ has no nonaccessible vertex and no $S$-dilation. Besides, the three edges are $S$-disjoint edges since they have different end vertices and one edge begins at vertex 3 and two edges begin at vertex 0 but they come from different subsystems.
According to Theorem 2 or 3 the switched linear system is structurally controllable. On the other hand, the system matrices of each subsystem of corresponding subgraph are:

$$A_1 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad B_1 = \begin{bmatrix} 0 \\ 0 \\ \lambda_1 \end{bmatrix}; \quad A_2 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & \lambda_2 \end{bmatrix}, \quad B_2 = \begin{bmatrix} \lambda_3 \\ 0 \end{bmatrix}.$$  

The controllability matrix can be calculated and can be shown to have $g$-rank=3. In addition, there exist a dilation in union graph Fig. 1(c), which shows that the condition in Theorem 1 is not necessary for structural controllability.

For further extension purpose, next we will use examples to illustrate that the dependence among system parameters will make some edges ‘useless’ or ‘excessive’ in judging the structural controllability. See the following switched linear system first

$$A_1 = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \quad B_1 = \begin{bmatrix} \lambda_1 \\ \lambda_2 \end{bmatrix}; \quad A_2 = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \quad B_2 = \begin{bmatrix} \lambda_3 \\ \lambda_4 \end{bmatrix}.$$  

According to Theorem 2 or 3, this system is structurally controllable. However, if dependent parameters are considered, see the following switched linear system (a linear system actually)

$$A_1 = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \quad B_1 = \begin{bmatrix} \lambda_1 \\ \lambda_2 \end{bmatrix}; \quad A_2 = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \quad B_2 = \begin{bmatrix} \lambda_1 \\ \lambda_2 \end{bmatrix}.$$  

The dependence of all the parameters in matrix $B_1$ and $B_2$ makes this system not structurally controllable and the results in Theorem 2 and 3 not hold, even though it would be structurally controllable if the parameters in $B_2$ are replaced with $\lambda_3$ and $\lambda_4$ or simply remove $\lambda_1$ or $\lambda_2$ in the second subsystem.

### IV. Conclusions and Future Work

In this paper, structural controllability for switched linear systems has been investigated. Combining the knowledge in the literature of switched linear systems and graph theory, several graphic necessary and sufficient conditions for the structurally controllability of switched linear systems have been proposed. These graphic interpretations provide us a better understanding on...
how the graphic topologies of switched linear systems will influence or determine the structural controllability of switched linear systems. This shows us a new perspective that we can design the switching algorithm to make the switched linear system structurally controllable conveniently just having to make sure some properties of the corresponding graph (union or colored union graph) are kept during the switching process. In this paper, the parameters in different subsystem models are assumed to be independent. A more general assumption is that some free parameters remain the same among different subsystems switching, i.e., dependence among subsystems. It turns out that our necessary and sufficient condition derived here would be a necessary condition under this dependence assumption. To obtain a full characterization for the dependent case needs further investigation.
