The weighted average quantile derivative (AQD) is the weighted expected value of the partial derivative of the conditional quantile function (CQF) weighted by a function of the covariates. We consider two weighting functions: a known function chosen by researchers and the density function of the covariates that is parallel to the average mean derivative in Powell, Stock, and Stoker (1989, *Econometrica* 57, 1403–1430). The AQD summarizes the marginal response of the covariates on the CQF and defines a nonparametric quantile regression coefficient. In semiparametric single-index and partially linear models, the AQD identifies the coefficients up to scale. In nonparametric nonseparable structural models, the AQD conveys an average structural effect under certain independence assumptions. Including a stochastic trimming function, the proposed two-step estimator is root-$n$-consistent for the AQD defined by the *entire* support of the covariates. To facilitate tractable asymptotic analysis, a key preliminary result is a new Bahadur-type linear representation of the generalized inverse kernel-based CQF estimator uniformly over the covariates in an expanding compact set and over the quantile levels. The weak convergence to Gaussian processes applies to the differentiable nonlinear functionals of the quantile processes.

1. INTRODUCTION

The weighted average quantile derivative (AQD) is the weighted expected value of the partial derivatives of the conditional quantile function (CQF), defined as

$$
\beta_W(\tau) \equiv \mathbb{E}[\nabla Q(\tau | X)W(X)],
$$

where $Q(\tau | X)$ is the $\tau$th CQF of the dependent variable $Y$ given the continuous covariates $X$. The weighting function $W(X)$ defines the AQD that conveys information of the distributional impacts of the covariates on the response variable. Thus, the AQD defines a nonparametric quantile regression (QR) parameter that summarizes the marginal effect of $X$ on the $\tau$th CQF. Policy makers may specify $W(X)$ for counterfactual analysis to evaluate distributional policy effects (e.g.,
For $W(X) = f(X)$ the density of the covariates, we estimate the data-driven density weight nonparametrically. We show that the proposed estimators of $\beta_W(\tau)$ are $\sqrt{n}$-consistent and weakly converges to a Gaussian process indexed by $\tau$. It follows that we can conduct joint inference on the Hadamard-differentiable functionals of the conditional or average quantile process, which can be nonlinear functionals. In an intermediate step, we provide a new Bahadur-type linear representation for the generalized inverse kernel-based CQF estimator uniformly over the covariates in an expanding compact set and over the quantile levels, which can be of independent interest.

The AQD is a nonparametric alternative to the linear QR by Koenker and Bassett (1978), just as the average mean derivative (AMD), $E[\nabla E[Y|X]]$, is a nonparametric alternative to the ordinary least-squares (OLS) estimation. Powell, Stock, and Stoker (1989) introduce the density-weighted AMD $E[\nabla E[Y|X]/f(X)]$, which has received a lot of attention: Härdle and Stoker (1989), Powell and Stoker (1996), Nishiyama and Robinson (2000), Schafgans and Zinde-Walsh (2010), Cattaneo, Crump, and Jansson (2010, 2013, 2014a, 2014b), and Cattaneo and Jansson (2018), to mention just a few. When the economic theory implies some semiparametric single-index and partially linear models, the AQD identifies the coefficient up to scale, e.g., Chaudhuri, Doksum, and Samarov (1997), Lee (2003), and Hoderlein and Mammen (2009). The AQD gives a simple picture of the impacts of the covariates on the outcome distribution and is more robust against possible extreme values than the mean estimators. In nonparametric nonseparable structural models, the derivative of the CQF has causal interpretation of continuous quantile treatment effects, under certain conditional independence assumptions, e.g., Chesher (2003), Chernozhukov and Hansen (2005), Hoderlein and Mammen (2007), Matzkin (2007), and Sasaki (2015), among others. The AQD is a simple summary statistic for the quantile treatment effects by averaging over the covariates.

The AQD is a nonparametric alternative to the linear QR by Koenker and Bassett (1978), just as the average mean derivative (AMD), $E[\nabla E[Y|X]]$, is a nonparametric alternative to the ordinary least-squares (OLS) estimation. Powell, Stock, and Stoker (1989) introduce the density-weighted AMD $E[\nabla E[Y|X]/f(X)]$, which has received a lot of attention: Härdle and Stoker (1989), Powell and Stoker (1996), Nishiyama and Robinson (2000), Schafgans and Zinde-Walsh (2010), Cattaneo, Crump, and Jansson (2010, 2013, 2014a, 2014b), and Cattaneo and Jansson (2018), to mention just a few. When the economic theory implies some semiparametric single-index and partially linear models, the AQD identifies the coefficient up to scale, e.g., Chaudhuri, Doksum, and Samarov (1997), Lee (2003), and Hoderlein and Mammen (2009). The AQD gives a simple picture of the impacts of the covariates on the outcome distribution and is more robust against possible extreme values than the mean estimators. In nonparametric nonseparable structural models, the derivative of the CQF has causal interpretation of continuous quantile treatment effects, under certain conditional independence assumptions, e.g., Chesher (2003), Chernozhukov and Hansen (2005), Hoderlein and Mammen (2007), Matzkin (2007), and Sasaki (2015), among others. The AQD is a simple summary statistic for the quantile treatment effects by averaging over the covariates.

The paper is concerned with the estimation and inference of the weighted AQD in (1):

$$\beta_W(\tau) = -E \left[ Q(\tau|X) \left( \nabla W(X) + W(X) \frac{\nabla f(X)}{f(X)} \right) \right],$$

where the equality follows by integration by parts and assuming the covariates have zero density on the boundary. Hence, the weighted AQD can be interpreted as a weighted average CQF. More generally, we focus on the weighted average quantile response (AQR)

$$\beta_\phi(\tau) \equiv E \left[ Q(\tau|X)\phi(X) \right].$$

When the weight $\phi(X) = -\nabla W(X) - W(X) \nabla f(X)/f(X)$, $\beta_\phi(\tau) = \beta_W(\tau)$ is the weighted AQD in (2). We propose a two-step estimator for $\beta_W(\tau)$: The first step is leave-one-out nonparametric kernel-based estimation of the unknown functions $f(x)$, $\nabla f(x)$, and $Q(\tau|X)$. The CQF is estimated by a generalized inverse of the estimated conditional distribution function, $\hat{Q}(\tau|X) \equiv \inf\{y : \hat{F}_Y(y|X) \geq \tau\}$, where $\hat{F}_Y(y|X)$ is a smoothed local constant regression estimator. In the second
step, the expectation is replaced by its sample analog involving a stochastic trimming function to account for estimating the CQF near the boundary with small density. A stochastic trimming function selects a compact interior support of the covariates by removing the observation $i$ if $\hat{f}_{XY}(X_i, \hat{Q}(\tau | X_i)) < \delta$, where the trimming parameter $\delta$ vanishes at an appropriate rate as the sample size grows. Hence, our estimator is consistent for $\beta_\phi(\tau)$ defined by the entire support of $X$.

We present three main results. First, to the best of our knowledge, this is the first paper to provide the limit theory for the weighted AQD defined by the whole support of $X$, which has zero density on the boundary and can be unbounded. Our limit theorems also cover the case when the estimand is defined by a compact interior support of $X$ using a nonvanishing trimming parameter, commonly used in previous research discussed below. Our tractable approach may be applied to other multistep estimation problems based on a preliminary nonparametric kernel-based estimator, where the stochastic trimming is required but often avoided due to technical complication.

The second result is the density-weighted AQD by choosing $W(X) = f(X)$. The density weight inherits the spirit of the AMD in Powell et al. (1989). The density-weighted AQD has a simplified expression in $\beta_\phi$ with $\phi(X) = -2\nabla f(X)$ by eliminating the denominator in (2). Consequently, compared with the AQD with a known weight in (2), the density-weighted AQD estimator allows the trimming parameter to vanish at a faster rate, so the estimator trims away less observations in finite samples and also assumes weaker smoothness conditions on the distributions. We also provide an optimal bandwidth that minimizes the mean squared error (MSE), using the results of Powell and Stoker (1996).

The third result is a Bahadur-type linear representation of the CQF estimator that is uniform over values of the covariates in a sequence of expanding compact interior support and over quantile levels in a compact subset of $(0, 1)$. The new Bahadur-type representation allows us to use the stochastic trimming function to select the interior support of the covariates and the quantile. Hence, it is particularly useful when the CQF is involved in a multistep estimation procedure, for example, the first-price auction in Guerre, Perrigne, and Vuong (2000) and Marmer and Shneyerov (2012) and the quantile correlated random coefficients panel data model in Graham et al. (2018). We also derive the weak convergence of the conditional quantile process estimator.

Now, we discuss our contributions of the above three results to the related literature. The weighted AQD in (1) and (2) are first estimated by Chaudhuri et al. (1997) using local polynomial estimators. Lee (2003) estimates (1) in a partially linear model. Recently, Belloni et al. (2019) develop a nonparametric series framework and perform inference on linear functionals of the CQF, including the AQD with a known weight. We add to the literature by (i) an explicit expression of the first-order bias that could be useful for robust inference in finite samples. (ii) Our asymptotic analysis accounts for the estimation error of the density weight. (iii) Using a stochastic trimming function, we are able to conduct inference on the average quantile process defined by the whole support of $X$. In contrast,
the abovementioned papers all employ a fixed trimming function for technical simplification without losing their main focus. Consequently, their estimands are defined by the interior support of the regressors. For the AQD to serve as a nonparametric QR coefficient or in some economic applications, their estimands would be different objects from the AQD defined by the entire support. Our stochastic trimming approach has two advantages of consistency and efficiency over the fixed trimming approach. In a nonparametric model, our estimator reaches the semiparametric efficiency bound (Newey, 1990). In the semiparametric single-index and partially linear models, a trimming function and the weighting function do not affect the consistency of the estimators. But when the optimal weight in terms of efficiency is concerned, a fixed trimming parameter results in efficiency loss, as noted in Lee (2003).

We contribute a new tractable approach to handle the stochastic trimming in asymptotic analysis. Toward this end, we apply the result of the nonparametric kernel-based estimators in Hansen (2008) and Cattaneo et al. (2013). In particular, to account for the entire support of the covariates, we face two challenges: The first issue is the “denominator problem” for estimating the CQF when the density is small near the boundary. Second, we derive the limit theory by plugging a Bahadur-type representation for the CQF estimator into the two-step AQD estimator, which becomes a $U$-statistic. The linear representation of $\hat{Q}(\tau | X)$ is uniform over $X$ in a compact inner subset of the support, rather than the entire support. The key to overcome these two problems is to incorporate a Bahadur-type representation of $\hat{Q}(\tau | X)$ on an expanding compact interior support with a stochastic trimming function. The smoothed estimator $\hat{F}_Y(y|x)$ utilizes the uniform convergence results on expanding interior support in Hansen (2008) and Cattaneo et al. (2013). The trimming function selects the expanding compact interior support by controlling the lower bound of the joint density $f_{XY}(X, Q(\tau | X))$ converging to zero. Then, we derive a Bahadur representation for the generalized inverse estimator of the CQF uniformly over $X$ in this trimmed interior support at an appropriate rate as the sample grows, depending on a tradeoff between the tail behavior of the distribution and the estimation error from the CQF. Therefore, the trimmed compact interior support, where we have the uniform linear representation for $\hat{Q}(\tau | X)$, is expanding to the entire support as the sample grows.

Finally, our third result contributes a Bahadur representation of the generalized inverse smoothed estimator for the CQF. Bhattacharya and Gangopadhyay (1990) provide a Bahadur representation uniformly over the bandwidth, and Dabrowska (1992) derives the uniformity over the quantiles. For the local polynomial estimator of the CQF, Chaudhuri et al. (1997) and Kong, Linton, and Xia (2010) derive Bahadur representations for uniformity in the covariates $X$, Qu and Yoon’s (2015) result is uniform over the quantile $\tau$, and Guerre and Sabbah (2012) and Fan and Guerre (2016) provide the uniformity in $X$ and $\tau$. To extend their Bahadur representations to uniformity on expanding interior supports, the uniform convergence rate is penalized by the lower bound of the density at a slower rate, as noted in Hansen (2008). As a result, compared with our local constant
estimator, using a local linear quantile estimator trims more observations in finite samples.

The paper proceeds as follows. In Section 2, we discuss applications of the AQD. Section 3 introduces the estimators. In Section 4, we first show a uniform linear representation and weak convergence for the nonparametric kernel-based CQF estimation. The AQD estimators are $\sqrt{n}$-consistent and asymptotically normal. We suggest a consistent estimator for the asymptotic covariance matrix and an optimal bandwidth choice. In Section 5, by a simple simulation study, we compare the proposed AQD estimator with the AMD estimator in Powell et al. (1989), the linear QR estimator in Koenker and Bassett (1978), and the OLS for the semiparametric partially linear models. We also implement several bootstrap-based confidence intervals (CIs). All proofs are in the Appendix.

2. APPLICATIONS

We discuss applications of the AQD by starting with a general nonparametric nonseparable structural model. We demonstrate how the AQD captures informative causal features under certain conditional independence assumptions. By imposing further assumptions on the data generating processes (DGPs) and the structural equations, the AQD estimates the coefficients (up to scale) in semiparametric QR models. Another application relates to the counterfactual distribution or decomposition analysis literature. We discuss some earlier work that is most related to ours; more details are in their references therein.

Consider the general setting in Newey and Stoker (1993), $Y = \phi(X,e)$, where $e$ captures the unobserved individual heterogeneity and could be multidimensional. Let $X = (X_1, X_2)'$ and $X_1$ be conditionally independent of $e$ given $X_2$. Hoderlein and Mammen (2007) and Sasaki (2015) investigate causal interpretation of the derivative of the CQF, which identifies a weighted average of heterogeneous structural partial effects among the subpopulation of individuals at the conditional quantile of interest.

A common identification strategy assumes that the structural function $\phi$ is strictly increasing in the scalar unobservable $e$. Then, the CQF of $Y$ given $X$ identifies the structural function $\phi$ up to a normalization on $Q_e(\tau|X_2)$,

$$Q(\tau|X) = \phi(X, Q_e(\tau|X)) = \phi(X, Q_e(\tau|X_2)). \quad (4)$$

Therefore, the partial derivative of the CQF with respect to $X_1$, $\partial Q(\tau|X)/\partial X_1$, identifies the structural derivative, $\partial \phi(X, Q_e(\tau|X_2))/\partial X_1$, which is the causal effect of $X_1$ while leaving the value of the unobserved variable $e$ unchanged at $Q_e(\tau|X_2)$.

Further assume quantile independence and normalization such that (4) yields $\phi(X, Q_e(\tau)) = \phi(X, \tau)$, which is the $\tau$th quantile treatment response defined in Chernozhukov and Hansen (2005). It follows that for a nonseparable single-index
model $Y = \phi(X' \beta_0, e)$, $\beta_W(\tau)$ identifies the index coefficient $\beta_0$ up to scale, e.g., Chaudhuri et al. (1997) and a rank estimator in Khan (2001). Then, the structural function $\phi$ can be further estimated by a nonparametric QR of $Y$ on the estimated index $X' \hat{\beta}_W(\tau)$.

The partially linear and single-index models relax restrictive parametric assumptions and ease the curse of dimension in nonparametric estimation. For a single-index QR model, $Y = \phi_t(X' \beta_t) + e_t$ and $Q_{e_t}(\tau | X) = 0$. The weighted AQD identifies the coefficient $\beta_t$ up to scale, $\beta_W(\tau) = \beta_t \mathbb{E}[\phi_t'(X' \beta_t) W(X)]$. For example, Wu, Yu, and Yu (2010) propose an iterative algorithm, and Kong and Xia (2012) propose an adaptive estimation procedure.

The weighted AQD relates to the counterfactual distribution literature by the choice of the weighting function $W(X)$; see Chernozhukov et al. (2013) and the references therein. For example, the policy maker may change the covariate distribution exogenously to some probability density function $f^*(X)$, as in Rothe (2010), and consider a simple counterfactual, “what would the AQD have been if individuals’ attributes had been distributed by $f^*(X)$?” By choosing $W(X) = f^*(X)/f(X)$, the weighted AQD $\beta_W(\tau) = \int \nabla Q_Y(\tau | x) f^*(x) dx = \mathbb{E}[\nabla Q_Y(\tau | X) f^*(X)/f(X)] = -\mathbb{E}[Q_Y(\tau | X) \nabla f^*(X)/f(X)]$ is the counterfactual AQD. Our estimator for $\beta_W$ is directly applicable when $W(X)$ is known. The limit theory for an estimated $W(X)$ can be modified using the general results in the Appendix.

3. ESTIMATION

The data consist of $n$ observations $(X_i', Y_i)'$, $i = 1, \ldots, n$, which is an independently and identically distributed random sample from a distribution $F_{XY}(X, Y)$. The $\tau$th CQF of $Y$ given $X$ is $Q(\tau | X) \equiv \inf \{y : F_Y(y | X) \geq \tau \}$, where $F_Y(y | X)$ is the conditional cumulative distribution function (CDF) of $Y$ given $X$.

We propose two-step estimators for three estimands: the weighted AQR $\beta_\phi(\tau)$ in (3), the weighted AQD $\beta_W(\tau)$ in (2), and the density-weighted AQD $\beta_f(\tau) = \mathbb{E}[\nabla Q(\tau | X) f(X)] = -2 \mathbb{E}[Q(\tau | X) \nabla f(X)]$. (5)

The first step is leave-one-out nonparametric estimation of the unknown functions. The second step is the sample analog involving a stochastic trimming function $1\{X_i \in \hat{S}\}$:

$$\hat{\beta}_\phi(\tau) = \frac{1}{n} \sum_{i=1}^{n} \frac{\hat{Q}(\tau | X_i) \phi(X_i) 1\{X_i \in \hat{S}\}}{n}$$

(6)

This specification includes many models as special cases, for example of a selection model where $X_1$, $X_2$, and $Y = X_1' \beta_1 + e_1$ are observed only if the unobserved $Z_2' = X_2' \beta_2 + e_2 > 0$. Assuming $(e_1, e_2)$ is independent of $(X_1, X_2)$, $Q_V(\tau | (X_1, X_2, Z_2' > 0) = X_1' \beta_1 + Q_{e_1} (\tau | Z_2' > 0)$. If $X_2$ has no variables in common with $X_1$, then the AQD identifies the structural parameter $\beta_1$ and the selection parameter $\beta_2$ up to scale. If $X_1' \beta_1$ and $X_2' \beta_2$ are the same, then it is the truncated Tobit model, as discussed in Stoker (1986).
\[ \hat{\beta}_W(\tau) = -\frac{1}{n} \sum_{i=1}^{n} \hat{\mathcal{Q}}(\tau|X_i) \left( \nabla W(X_i) + \frac{\nabla \hat{f}(X_i)}{\hat{f}(X_i)} W(X_i) \right) 1\{X_i \in \hat{\mathcal{S}}\}, \]

(7)

\[ \hat{\beta}_f(\tau) = -\frac{2}{n} \sum_{i=1}^{n} \hat{\mathcal{Q}}(\tau|X_i) \nabla \hat{f}(X_i) 1\{X_i \in \hat{\mathcal{S}}\}, \]

(8)

for a quantile level \( \tau \in T = [\varepsilon, 1 - \varepsilon] \) for \( \varepsilon \in (0, 1/2) \). Following Powell et al. (1989), a more interpretable rescaled density-weighted AQD is defined as \( \hat{\beta}_s = \hat{\beta}_f / \mathbb{E}[f(X)] \), with a normalized density weight \( W(X) = f(X) / \mathbb{E}[f(X)] \). The scaled estimator is \( \hat{\beta}_s(\tau) = \hat{\beta}_f(\tau) / (n^{-1} \sum_{i=1}^{n} \hat{f}(X_i)) \).

Next, we describe each component in the estimators. The leave-one-out kernel estimator for the density function of \( X \) at \( X_1 \) is \( \hat{f}(X_1) = (|H_1|(n-1))^{-1} \sum_{j \neq i} K(H_1^{-1} (X_j - X_i)) \), where \( K(u) = \prod_{s=1}^{d} k(u_s) \) is a \( v \)-th order multivariate product kernel and the bandwidth matrix \( H_1 \) is the \( d \times d \) identity matrix multiplied by \( h_1 \), a positive sequence of \( n \). The covariates \( X \) can be normalized by the standard deviations, so that the bandwidths are equal to the same \( h_1 \) for all components of \( X \) for simplicity.

The CQF is estimated by inverting the estimated conditional CDF, \( \hat{\mathcal{Q}}(\tau|X) \equiv \inf\{y : \hat{F}_Y(y|X) \geq \tau\} \), where

\[ \hat{F}_Y(y|X_i) = \frac{1}{|H|(n-1)} \frac{1}{\hat{f}(X_i)} \sum_{j \neq i} G \left( \frac{y - Y_j}{h_0} \right) K(H^{-1} (X_j - X_i)) \]

with a kernel of order \( v \) and a bandwidth matrix \( H \). The indicator function \( 1\{Y_j \leq y\} \) for the dependent variable is smoothed by a cumulative kernel \( G(z) = \int_{-\infty}^{z} g(t)dt \) with a second-order kernel \( g \) and bandwidth \( h_0 \).

The CQF estimator by the generalized inverse is monotone in \( \tau \) by construction. However, the CDF estimator is not increasing in \( y \) when we use a bias-reducing or higher-order kernel \( K \). Chernozhukov, Fernández-Val, and Galichon (2010) propose a generic rearrangement method to get a monotonized version of the estimate \( \hat{F}_Y(y|X_i) \), which preserves the same asymptotics as \( \hat{F}_Y(y|X_i) \). Then, the CQF can be estimated by \( \hat{\mathcal{Q}}(\tau|X) \equiv \inf\{\hat{F}_Y(y|X) \geq \tau\} \) in practice.\(^2\)

The trimming function \( 1\{X_i \in \hat{\mathcal{S}}\} \) is defined by a small enough positive trimming parameter \( \delta \), which can be a constant or a positive sequence converging to zero, and \( \mathcal{S} \equiv \{x : f_{XY}(x, Q(\tau|x)) \geq \delta\} \). To estimate the AQR and the AQD at a particular quantile level \( \tau \), let \( \hat{\mathcal{S}} \equiv \{x : \hat{f}_{XY}(x, \hat{\mathcal{Q}}(\tau|x)) \geq \delta\} \). The trimming parameter \( \delta \) can be a constant that defines an interior support of \( X \) or a sequence \( \delta = \delta_n \) converging to zero that defines a sequence of expanding sets converging to the

\(^2\)Note that the weighted AQD \( \hat{\beta}_W(\tau) \) is a nonparametric object of interest, which is a summary statistic of the marginal effect of \( X \) on the CQF. We do not assume that \( x' \hat{\beta}_W(\tau) \) is the CQF and is monotone in \( \tau \) for all \( x \). However, quantile crossings occur in the single-index and partially linear models in Section 2, which is a fundamental problem for (semi)parametric QR models. In particular, Phillips (2015) shows that quantile crossings are inevitably present with positive probability in quantile predictive regressions.
entire support $X \subseteq \mathbb{R}^d$.\textsuperscript{3} The conditions on the tuning parameters $h, h_0, h_1, \nu, \nu_1, \delta$ are specified in Assumptions 3 and 4 in Section 4.

The derivative can only be calculated for the continuous covariates. When the covariates contain discrete components, the same estimation works for each point in a finite set of the realized values of the discrete components.

4. ASYMPTOTIC PROPERTIES

We provide a Bahadur-type representation for the CQF estimator uniformly in the quantiles and the covariates in Section 4.1. We also show the weak convergence of the conditional quantile process indexed by the quantile, for a given value of the regressors. Section 4.2 presents the limit theories for our estimators of the AQR $\beta_\phi$, the density-weighted AQR $\beta_f$, and the weighted AQR $\beta_w$. In Section 4.3, we provide a consistent estimator of the asymptotic covariance matrix. In Section 4.4, we provide an optimal bandwidth choice. Limits are taken as $n \to \infty$ unless otherwise noted. We start with regularity assumptions. The joint density of $X$ and $Y$ is uniformly continuous in $X$ and bounded; $\partial^3 F_Y(y|x)/\partial y^3$ is uniformly continuous in $y$ and bounded.

Assumption 1..

(i) $X \times Y$ is convex. $f(x)$ is uniformly bounded above. $\lim_{x \to \partial X} f(x) = 0$. $\lim_{x \to \partial X} Q(\tau|x)$ exists for all $\tau \in [\varepsilon, 1 - \varepsilon]$, for some small $\varepsilon > 0$.

(ii) For $x \in X$, $y \in Y$, and $\tau \in [0, 1]$, the partial derivatives of $F_Y(y|x)$ and $Q(\tau|x)$ with respect to $x$ of order $p$, are uniformly continuous in $x$ and bounded; $\partial^3 F_Y(y|x)/\partial y^3$ is uniformly continuous in $y$ and bounded.

Assumption 2 (Kernel). (K) The kernel function $k$ is Lipschitz continuous, bounded, symmetric, with convex bounded support, and of order $\nu$, i.e., $\kappa_j \equiv \int x^j k(x)dx = 0$, for $j < \nu$ and $\kappa_\nu \in (0, \infty)$. The first derivative $k'(x)$ is bounded and integrable.

(G) The second-order kernel $g$ is bounded and symmetric. When $g$ has an unbounded support and $Y \subset \mathcal{R}$, there exist some positive constants $C, L < \infty$ and $m > 4$ such that $|g(u)| \leq C|u|^{-m}$, for $|u| > L$.

Assumption 2(K) imposes standard kernel conditions, e.g., Powell et al. (1989) and Hansen (2008). Assumption 2(G) is used to characterize the first-order bias from smoothing the indicator function with $G((y - Y)/h_0)$. The commonly used Gaussian kernel satisfies Assumption 2(G) that restricts the tail behavior of the kernel function $g$ with an unbounded support when $Y$ does not have a full support on $\mathcal{R}$.

\textsuperscript{3}For the denominator problem, Robinson (1988), Härdle and Stoker (1989), Lavergne and Vuong (1996), Ichimura and Todd (2007), and Escanciano, Jacho-Chávez, and Lewbel (2014), among others, use a similar stochastic trimming approach by bounding the density of $X$ away from zero. Because we are dealing with an additional problem of estimating the CQF and its uniform linear representation, trimming on $f(X)$ is not sufficient. Similarly, for the series estimator in Belloni et al. (2019), their AQD is defined by a fixed interior support where $f_{XY}(x, Q(\tau|x))$ is bounded away from zero.
4.1. Conditional Quantile Function

We give a condition on the trimming parameter $\delta$ in the trimming function $1\{X_i \in \tilde{S}\}$ via an expanding set $C_n \equiv \{x : \|x\| \leq c_n\}$, where a positive sequence $c_n \to \infty$ and $\|x\| = |x'|^{1/2}$. Then, we build on and extend the uniform convergence results of kernel-based estimators on an expanding interior support in Hansen (2008) and Cattaneo et al. (2013) to specify the condition on $c_n$. Specifically, for any positive sequence $\delta = \delta_n \to 0$, define $S = S_n \equiv \{x : \inf_{\tau \in T} f_{XY}(x, Q(\tau|x)) \geq \delta\}$ that approaches $X$ as $n \to \infty$. There exists such an expanding set $C_n$ equal to the convex hull of $S$. We can show that $\delta = \inf_{\tau \in T} f_{XY}(x, Q(\tau|x))$ with $x$ on the boundary of $C_n$, i.e., $\|x\| = c_n$. When $X$ is convex, we can write $\delta = \inf_{x \in C_n, \tau \in T} f_{XY}(x, Q(\tau|x))$.4

We remark that the convex support condition in Assumption 1(i) is used to conveniently specify the condition on the trimming parameter $\delta$ and is for notational simplicity. Nonetheless, the convex support assumption is not uncommon in the literature; for example, it can be implied by other smoothness conditions on $f(x)$, $f_Y(y|x)$, or $Q(\tau|x)$ as in Guerre and Sabbah (2012) and Qu and Yoon (2015), among others. We can allow a nonconvex support by letting Assumption 1 be local following Qu and Yoon (2015) in the sense that the restrictions are on neighborhoods surrounding $X \times Y$ rather than on the support of $(X', Y)$ by a slight abuse of notation. Then, our results can be applied to the case when the support is nonconvex and is a union of convex sets.

THEOREM 1 (Bahadur representation). Let Assumptions 1 and 2 hold with $p_x \geq v$. Let $\delta^{-1} \left( \sqrt{\log n/(n h^d_0)} + h_0^2 + h^v \right) \to 0$. Let $\delta$ be a constant or a sequence $\delta = \delta_n = \inf_{\tau \in T} f_{XY}(x, Q(\tau|x)) \to 0$ with $\|x\| = c_n \to \infty$ and $\limsup_{n \to \infty} \log(c_n)/\log n < \infty$. Then,

$$\sup_{\tau \in T} \sup_{x \in S} \left| \hat{Q}(\tau|x) - Q(\tau|x) \right| = O_p \left( \frac{1}{\delta} \left( \sqrt{\frac{\log n}{n h^d}} + h_0^2 + h^v \right) \right).$$

Furthermore, let $\delta^{-1} \sqrt{\log n/(n h^d_0)} \to 0$. Then, for any $\tau \in T$ and $x \in S$,

$$\hat{Q}(\tau|x) - Q(\tau|x) = \frac{1}{n|H|} \sum_{i=1}^{n} K \left( H^{-1}(X_i - x) \right) \left( \tau - G \left( \frac{Q(\tau|x)}{h_0} \right) \right) + R_n(\tau, x),$$

(9)

4We can normalize $X$ such that the support $X$ is centered at zero without loss of generality. To see the relationship between $\delta$ and $c_n$, let $T = \{\tau\}$ be a singleton for simplicity. Since $S$ is compact, $\tilde{x}$ on the boundary of the convex hull of $S$ is also on the boundary of $S$, and hence, $f_{XY}(\tilde{x}, Q(\tau|x)) \geq \delta$. Suppose to the contrary that the inequality is strict, i.e., $f_{XY}(\tilde{x}, Q(\tau|x)) = \alpha \delta > \delta$ for a constant $\alpha > 1$. By the assumption $\lim_{h \to 0} f(x) = 0$, $\lim_{h \to 0} f_{XY}(x, Q(\tau|x)) = 0$, and hence, $S$ is a strict subset of $\mathcal{X}$, for any $\delta > 0$. So $X \cap S$ is not empty. By continuity, there exists $\eta > 0$ such that for $x \in \{x \in X \cap S^c : \|x - \tilde{x}\| \leq \eta\}$, $|f_{XY}(x, Q(\tau|x)) - f_{XY}(\tilde{x}, Q(\tau|x))| \leq \delta$. So $f_{XY}(x, Q(\tau|x)) \geq f_{XY}(\tilde{x}, Q(\tau|x)) - \delta = (\alpha - 1)\delta > \delta$ that contradicts $x \in X \cap S^c$. Therefore, $f_{XY}(\tilde{x}, Q(\tau|x)) = \delta$. When $X$ is convex, $S = C_n$ for $n$ large enough, and hence, $\delta = \inf_{x \in C_n} f_{XY}(x, Q(\tau|x))$ by construction.
where the remainder term $R_n(\tau, x)$ satisfies
\[
\sup_{x \in S, \tau \in T} |R_n(\tau, x)| = O_p\left(\frac{\log n}{\delta^2 nh^d} \left(\frac{1}{\sqrt{h_0}} + \frac{1}{\delta}\right)\right) + O_p\left(\frac{h^v + h^2_0}{\delta^2} \left(\sqrt{\frac{\log n}{nh^d h_0}} + \frac{h^v + h^2_0}{\delta}\right)\right).
\] (10)

The linear representation is useful for analyzing large sample properties of the final plug-in estimators under different applications. The CQF estimator inherits the uniform convergence rate of the conditional CDF estimator $\hat{F}_Y(y|X)$. The Bahadur representation allows for the optimal rate for estimating the CQF. In the uniform convergence rate of the remainder term $R_n$, the second part in (10) is of smaller order if the estimator is undersmoothed by assuming $\sqrt{nh^d(h_0^2 + h^v)} \to 0$.

Theorem 2 below shows the weak convergence of the empirical conditional quantile process $\{x \mapsto \hat{Q}(\tau|x) : \tau \in T\}$. When the interest is to conduct inference on the CQF, Theorem 2 enables the inference method in Fan and Liu (2016), who develop a new CI interval from any conditional quantile process estimator that weakly converges to a Gaussian process.

THEOREM 2 (Weak convergence). Let the conditions in Theorem 1 hold. Furthermore, let $\sqrt{nh^d(h_0^2 + h^v)} \to 0$. Then, for any $x \in S$, $\sqrt{nh^d}(\hat{Q}(-\cdot|x) - Q(-\cdot|x)) \implies \mathbb{G}(-\cdot|x)$ that is a zero-mean Gaussian process $\mathbb{G}(-\cdot|x)$ with covariance
\[
\text{Cov}(\mathbb{G}(\tau_1|x), \mathbb{G}(\tau_2|x)) = \frac{\tau_1(1 - \tau_2)}{f(x) f_Y(Q(\tau_1|x)|x) f_Y(Q(\tau_2|x)|x)} \left(\int k(v)^2 dv\right)^d,
\]
for any $\tau_1 \leq \tau_2 \in T$.

4.2. Weighted Average Quantile Response

We first establish asymptotic linearity of the estimator for the weighted AQR with a known weight $\phi(X)$, $\beta_\phi(\tau) = \mathbb{E}[Q(\tau|x)\phi(X)]$ in (6). Theorem 3 also provides the preliminary results to analyze $\hat{\beta}_f$ and $\hat{\beta}_w$, where the weight is estimated. Let $\partial_k^1 g(x)$ denote the $k$th-order partial derivative of a generic function $g(x)$ with respect to the $k$th component of $x$ and $\partial_k g(x) \equiv \partial_k^1 g(x)$.

THEOREM 3 (Weighted AQR). Let the conditions in Theorem 1 hold with $p_s \geq v + 1$. For a measurable function $\phi : \mathcal{X} \mapsto \mathbb{R}^d$, assume the $p_s$th-order derivative of $\phi(x)$ to be uniformly continuous and bounded. Let the following conditions hold.

(i) $\mathbb{E}\left[\left\|\phi(X)\right\|^2 \left(\inf_{\tau \in T} F_X(X, Q(\tau|X))\right)^{-2}\right] < \infty$, $nh^{2d} \to \infty$, and $\sqrt{n}(h_0^2 + h^v) \to 0$.

(ii) $\sup_{x \in S, \tau \in T} \left\|\phi(x)\right\||R_n(\tau, x)| = o_p\left(n^{-1/2}\right)$, where the bound of $R_n$ is given in Theorem 1.

(iii) $\mathbb{E}\left[\left\|Q(\tau|X)\phi(X)\right\|I\{X \notin S\}\right] = o(n^{-1/2})$. 

Downloaded from https://www.cambridge.org/core. IP address: 207.241.225.226, on 11 Jun 2021 at 08:15:38, subject to the Cambridge Core terms of use, available at https://www.cambridge.org/core/terms. https://doi.org/10.1017/S0266466621000232
Then, uniformly in $\tau \in T$,
\[
\sqrt{n} \left( \hat{\beta}_\phi(\tau) - \beta_\phi(\tau) - \text{Bias}_{\phi}(\tau; h_0) \right)
= \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \left( \frac{\phi(X_i)}{f_Y(Q(\tau|X_i)|X_i)} (\tau - 1\{Y_i \leq Q(\tau|X_i)) + Q(\tau|X_i) \phi(X_i) - \beta_\phi(\tau) \right)
+ o_p(1),
\]
where
\[
\text{Bias}_{\phi}(\tau; h, h_0) \equiv E \left[ \frac{-\phi(X)}{f_Y(y|X)} \left( h_0^2 \kappa_{G2} \frac{\partial f_Y(y|X)}{\partial y} \right) \right] + f(X) \sum_{l=1}^{\nu} \frac{1}{l! (\nu - l)!} \sum_{k=1}^{d} \partial_{k}^{l} f_Y(y|X) \partial_{k}^{\nu-l} f(X) \bigg|_{y=Q(\tau|X)}
\]
and $\kappa_{G2} \equiv \int G'(z)z^2dz$.

The condition (i) in Theorem 3 is due to the $U$-process theory in Sherman (1994). The bandwidths are large enough to achieve asymptotic linearity. The bandwidths are small enough with possibly higher-order kernels to control the bias to vanish at a rate no slower than $\sqrt{n}$. Consequently, the nonparametric estimations of the density and CQF are undersmoothed, which is conventional in semiparametric estimation.

Our asymptotic theorems apply to both cases using fixed trimming and vanishing trimming approaches. The asymptotic linear representation in Theorem 3 coincides with Chaudhuri et al. (1997), where the weight $W$ serves as a trimming function to define a compact interior of the support of $X$. We further characterize the first-order bias from the CQF estimate, which vanishes at a faster rate under the condition $\sqrt{n}(h_0^2 + h^\nu) \to 0$.

The trimming parameter $\delta$ vanishes to zero at a rate specified by the conditions (ii) and (iii) in Theorem 3. The condition (ii) ensures $\delta$ to be large enough to control the sampling variation of estimating the CQF. The condition (iii) controls the trimming bias that depends on the tail behavior of the distribution $f_{XY}$ and ensures that $\delta$ is small enough for the estimator to approach the entire support. The trimming parameter $\delta$ trades off the estimation variance and the trimming bias, while the bandwidths $h$ and $h_0$ trade off the variance and bias of the preliminary estimators.

We use a standard approach to derive the limit theory by plugging a Bahadur-type representation for the CQF estimator into the two-step estimator, which becomes a $U$-statistic. The linear representation of $\hat{Q}(\tau|X) \equiv \sum_{i=1}^{n} \phi(X_i) / \sum_{i=1}^{n} \phi(X_i)$ in Theorem 1 has the joint density $f_{XY}(x, Q(\tau|X))$ in the denominator. Heuristically, we control the remainder terms in the linear representation of the final estimator to be of smaller order.

---

5Similar assumptions have been used in Lavergne and Vuong (1996), Ichimura and Todd (2007), and Khan and Tamer (2010), for example.
order based on \(1/f_{XY}(x, Q(\tau|x)) < 1/\delta\). In a semiparametric problem that involves the CQF, the conditional density \(f_f(Q(\tau|x)|x)\) is commonly assumed to be bounded away from zero for identification or for technical simplification. Assumption 1 implies that there exist some constants \(\delta \) and \(c\) such that \(\{x : f_f(Q(\tau|x)) > \delta\} = \{x : f_f(Q(\tau|x)|x) > c\}\). Therefore, using the conditional density, \(f_f(Q(\tau|x)|x)\) is equivalent to using the joint density \(f_{XY}(x, Q(\tau|x))\) in our asymptotic analysis. Exploiting the assumption \(f_f(Q(\tau|x)|x) > c\) would not improve the large sample properties by our approach.

Next, we present the asymptotic properties for the density-weighted AQD with an estimated weight \(\nabla \hat{f}(X)\) in (8) \(\hat{\beta}_f(\tau)\) and the scaled AQD \(\hat{\beta}_s(\tau) = \hat{\beta}_f(\tau)/(n^{-1}\sum_{i=1}^n \hat{f}(X_i))\). Assumption 3 gives specific conditions for the tuning parameters for \(\hat{\beta}_f\) and are sufficient for the conditions in Theorem 3. Let \(B_n \equiv \{X : f_{XY}(X, Q(\tau|X)) < \delta\}\). When uniformity over \(\tau \in T\) is considered, let \(B_n \equiv \{X : \sup_{\tau \in T} f_{XY}(X, Q(\tau|X)) < \delta\}\).

**Assumption 3** (Bandwidth—\(\hat{\beta}_f\)). The positive sequences \(h, h_1, h_0, \delta\) satisfy

\[
\sqrt{n}(h_0^2 + h^2 + h_1^2) \to C \in [0, \infty), \quad \delta^4 nh^{2d} h_0 \to \infty, \quad \delta^6 nh^{2d+2} \to \infty, \quad n h_1^2 \to \infty, \quad \text{and } \delta^5 n h_1^2 h_1^2 \to \infty.
\]

The trimming parameter \(\delta = \delta_n\) satisfies \(\int_{B_n} \|Q(\tau|X)\nabla f(X)\| f(X)dX = o(n^{-1/2})\).

**THEOREM 4** (Density-weighted AQD). Let the conditions in Theorem 1 hold with \(p_s \geq \max\{v + 1, v_1 + 2\}\) and \(\phi(X) = -2\nabla f(X)\). Let Assumption 3 hold. Define the influence function

\[
r_f(Z_i; \tau) = \frac{2\nabla f(X_i)}{f_f(Q(\tau|X_i)|X_i)} \left(1|Y_i \leq Q(\tau|X_i)| - \tau\right) + 2f_f(X_i) \nabla Q(\tau|X_i) - 2\beta_f(\tau).
\]

1. Then, \(\sqrt{n}\left(\hat{\beta}_f(\tau) - \beta_f(\tau) - \text{Bias}_f(\tau; h, h_0, h_1)\right) = n^{-1/2} \sum_{i=1}^n r_f(Z_i; \tau) + o_p(1)\), uniformly in \(\tau \in T\), where \(\text{Bias}_f(\tau; h, h_0, h_1) \equiv -2h_1^{v_1} k_{v_1}(v_1!)^{-1} \sum_{k=1}^d \mathbb{E}\left[Q(\tau|X) \partial_k^{\tau} \nabla f(X)\right] + \text{Bias}_\phi(\tau; h, h_0)\) and \(\text{Bias}_\phi(\tau; h, h_0)\) is defined in (11) with \(\phi(X) = -2\nabla f(X)\).

2. Let \(\sqrt{n}(h_0^2 + h^2 + h_1^2) \to 0\) such that \(\text{Bias}_f(\tau; h, h_0, h_1) = o(n^{-1/2})\). Then, the empirical process indexed by \(\tau \in T\) converges weakly to a zero-mean Gaussian process \(\sqrt{n}(\hat{\beta}_f(\cdot) - \beta_f(\cdot)) \Rightarrow \mathbb{G}_f(\cdot)\) with covariance

\[
\text{Cov}\left(\mathbb{G}_f(\tau_1), \mathbb{G}_f(\tau_2)\right) = 4\tau_1(1 - \tau_2) \mathbb{E}\left[\nabla f(X) \nabla f(X)'/f_f(Q(\tau_1|X)|X)f_f(Q(\tau_2|X)|X)\right] + 4\mathbb{E}\left[(f(X) \nabla Q(\tau_1|X) - \beta_f(\tau_1))(f(X) \nabla Q(\tau_2|X) - \beta_f(\tau_2))\right],
\]

for any \(\tau_1 \leq \tau_2 \in T\). For the scaled density-weighted AQD, \(\sqrt{n}(\hat{\beta}_s(\cdot) - \beta_s(\cdot)) = n^{-1/2} \sum_{i=1}^n (r_f(Z_i; \cdot)/\mathbb{E}[f(X)] - 2(W(X_i) - 1)\beta^*(\cdot) + o_p(1) \Rightarrow \mathbb{G}_s^*(\cdot)\) that is a
zero-mean Gaussian process with covariance

\[
\text{Cov}(\mathcal{G}^*(\tau_1), \mathcal{G}^*(\tau_2)) = 4\tau_1(1 - \tau_2)E\left[\frac{\nabla W(X)\nabla W(X)'}{f_Y(Q(\tau_1|X)|X)f_Y(Q(\tau_2|X)|X)}\right]
\]

\[+ 4E\left[(W(X)\nabla Q(\tau_1|X) - \beta^*(\tau_1) + W(X) - 1)\]
\[\times (W(X)\nabla Q(\tau_2|X) - \beta^*(\tau_2) + W(X) - 1)\right],
\]

for any \(\tau_1 \leq \tau_2 \in \mathcal{T}\).

Now, we consider the general weighted AQD \(\hat{\beta}_w(\tau)\) in (7). Assumption 4 below gives specific conditions for the tuning parameters for \(\hat{\beta}_w\).

**Assumption 4** (Bandwidth—\(\hat{\beta}_w\)). The positive sequences \(h, h_1, h_0, \delta\) satisfy

\[
\sqrt{n}(h^2_0 + h^v + h^v_1) \to C \in [0, \infty), \delta n^d h^d h_0 \to \infty, \delta^d n^d h^d \to \infty, \delta^d n^d h^d_1 \to \infty, \delta^d n^d h^d_1 \to \infty. \]

The trimming parameter \(\delta = \delta_n\) satisfies

\[
\int_{B_n} \|Q(\tau|X)\nabla(W(X)f(X))\|dX = o(n^{-1/2}).
\]

**THEOREM 5** (Weighted AQD). Let the conditions in Theorem 1 hold with \(p_x \geq \max\{v + 1, v_1 + 2\}\) and \(\phi(X) = -\nabla(W(X)f(X))/f(X)\). Let Assumption 4 hold. Assume the \((v_1 + 1)\)th-order derivative of \(W(X)\) to be uniformly continuous and bounded. Assume \(E[(W(X)^2/f(X))^2] < \infty\) and \(E[(W(X)^2/f(X))^2/f(X)^4] < \infty\).

1. Then, \(\sqrt{n}(\hat{\beta}_w(\tau) - \beta_w(\tau) - \text{Bias}_w(\tau; h, h_0, h_1)) = n^{-1/2} \sum_{i=1}^n r_w(Z_i) + o_p(1),\) uniformly in \(\tau \in \mathcal{T}\), where the influence function is

\[
r_w(Z_i) = \frac{\nabla(W(X_i)f(X_i))}{f_Y(Q(\tau|X_i)|X_i)f_Y(X_i)}\left(1\{Y_i \leq Q(\tau|X_i)\} - \tau\right)
\]

\[+ W(X_i)\nabla Q(\tau|X_i) - \beta_w(\tau),\]

and \(\text{Bias}_w(\tau; h, h_0, h_1) = \text{Bias}_\phi(\tau; h, h_0) + h^v_1 \kappa_{(v_1 + 1)} - \sum_{k=1}^d E\left[Q(\tau|X)W(X)/f(X)^2 \times (\nabla f(X)\hat{\alpha}_k f(X) - f(X)\hat{\alpha}_k \nabla f(X))\right]\), where \(\text{Bias}_\phi(\tau; h, h_0)\) is defined in (11) with \(\phi(X) = -\nabla(W(X)f(X))/f(X)\).

2. Let \(\sqrt{n}(h^2_0 + h^v + h^v_1) \to 0\) such that \(\text{Bias}_w(\tau; h, h_0, h_1) = o(n^{-1/2})\). Then, the empirical process indexed by \(\tau \in \mathcal{T}\) converges weakly to a zero-mean Gaussian process \(\sqrt{n}(\hat{\beta}_w(\cdot) - \beta_w(\cdot)) \Rightarrow \mathcal{G}_w(\cdot)\) with covariance

\[
\text{Cov}(\mathcal{G}_w(\tau_1), \mathcal{G}_w(\tau_2)) = \tau_1(1 - \tau_2)E\left[\frac{\nabla(W(X)f(X))\nabla(W(X)f(X))'}{f_Y(X, Q(\tau_1|X))f_Y(X, Q(\tau_2|X))}\right]
\]

\[+ E[(W(X)\nabla Q(\tau_1|X) - \beta_w(\tau_1))(W(X)\nabla Q(\tau_2|X) - \beta_w(\tau_2))],
\]

for any \(\tau_1 \leq \tau_2 \in \mathcal{T}\).

Our theorems show that the proposed estimators are asymptotically linear and weakly converge to Gaussian processes. It is worth noting the difference in
estimating the density-weighted AQD$\beta_f$ in Theorem 4 and the general weighted AQD$\beta_W$ in Theorem 5. First, estimating the density weight contributes an additional term $f(X)\nabla Q(\tau | X) - \beta_f(\tau)$. Thus, the estimation error of the density function is not ignorable to perform correct inference. Second, because the density appears in the denominator in $\beta_W$, the trimming bound $\delta$ vanishes at a slower rate. Thus, $\hat{\beta}_W$ trims more observations in finite samples than $\hat{\beta}_f$ does. Third, the smoothness conditions are weaker for $\hat{\beta}_f$ than for $\hat{\beta}_W$.

**Remark 1** (Efficiency). Since our estimands are explicit functions of the distribution, Newey (1990) implies that these nonparametric estimators reach the semiparametric efficiency bounds when the distribution is unrestricted. That is, the influence function of any asymptotically linear and regular estimator for our estimand is unique and hence efficient. It follows that our estimators reach the efficiency bounds of the weighted AQR and the (density-)weighted AQD, respectively. Other nonparametric estimations for the first-step unknown functions, such as series or local polynomial, will give the same asymptotic distribution.6

**Remark 2** (Choice of tuning parameters). Although the tail distribution conditions are not testable, we provide an example that satisfies the condition $\limsup_{n\to\infty} \log(c_n)/\log n < \infty$ in Theorem 1. When the tail of the joint distribution of $(X, Y)$ decays at an exponential rate, we can choose $c_n \propto (\log n)^q$, for some $q > 0$, and $\delta = \delta_n \propto n^{-b}$.7

An alternative set of sufficient conditions for the nonparametric tuning parameters in Theorems 4 and 5 is to let the positive sequences vanish at a polynomial rate, $h \propto n^{-a}$, $h_1 \propto n^{-c}$, $h_0 \propto n^{-\eta}$, and $\delta \propto n^{-b}$, for some positive constants, $a, b, c, \eta$:

For $\hat{\beta}_f$, choose $\nu > \frac{4d}{3}$, $a \in \left[\frac{1}{2\nu}, \frac{3}{8d}\right)$, $\nu_1 > \max\left\{d + 1, \frac{d+2}{2-2ad}\right\}$, $c \in \left[\frac{1}{2
u_1}, \min\left\{\frac{1}{2d+2}, \frac{1-ad}{d+2}\right\}\right]$, $\eta \in \left[\frac{1}{4}, 1-2ad\right)$, and $b < \min\left\{\frac{1}{4} \right.$ $(1-2ad-\eta), \frac{1}{2}(1-ad-c(d+2)), \frac{1}{6}(1-2ad)\left\}.$

For $\hat{\beta}_W$, choose $\nu > \frac{4d}{3}$, $a \in \left[\frac{1}{2\nu}, \frac{3}{8d}\right)$, $\nu_1 > \max\left\{d + 1, \frac{d+2}{2-2ad}\right\}$, $c \in \left[\frac{1}{2
u_1}, \min\left\{\frac{1}{2d+2}, \frac{1-ad}{d+2}\right\}\right]$, $\eta \in \left[\frac{1}{4}, 1-2ad\right)$, and $b < \min\left\{\frac{1}{6} \right.$ $(1-2ad-\eta), \frac{1}{4}(1-ad-c(d+2)), \frac{1}{6}(1-ad-cd), \frac{1}{8}(1-2ad)\left\}.$

These sufficient conditions suggest an upper bound of the convergence rate of the tuning parameter $\delta \propto n^{-b}$, i.e., $\delta$ cannot be too small, so that we can control the first-step estimation error. On the other hand, the condition

---

6 Specifically, Newey and Stoker (1993) calculate the efficiency bounds for the weighted average derivative for general loss functions, including conditional mean and quantiles, where the weighting function is a known function. By proceeding as in the proof of Theorem 3.1 in Newey and Stoker (1993), we can calculate the efficiency bounds for the density-weighted average quantile/mean derivatives where the density weight is estimated. We can verify that the estimators proposed in this paper and in Powell et al. (1989) are semiparametrically efficient, as implied by the result in Newey (1990). Since the proof closely follows Theorem 3.1 in Newey and Stoker (1993), we do not repeat the details to save space.

7 Suppose the joint distribution of $Z = (X, Y)$ to be proportional to $e^{-\|x\|^p}$, for some $p > 0$. The bandwidth assumption requires the trimming parameter $\delta$ to be bounded above by $\inf_{|x| \leq \delta, f_{XY}(x, Q(x))} e^{-\log n^m}$ that is larger than $n^{-b}$ by letting $q < 1$. A smaller $p$ results in a larger $q$, meaning that we could use more observations when $f_{XY}$ has a fatter tail.
\[ \int_{B_n} \| Q(\tau | X) \nabla f(X) \| f(X) dX = o(n^{-1/2}) \] in Assumptions 3 and 4 suggests that \( \delta \) cannot be too big, so that the trimming bias is of smaller order. To see these conditions are feasible in practice, we give a set of tuning parameters for \( \hat{\beta}_f \) in our Monte Carlo simulations.

**Remark 3** (Functionals of the weighted average quantile). Once the weak convergence of the quantile process is established in the above theorems, we can extend the results to the Hadamard-differentiable functionals of the quantile process \( \Gamma(\beta) \), which can be nonlinear functionals of the distributions. The functional delta method, e.g., Theorem 20.8 in van der Vaart (2000), implies the limit distribution and uniform inference on functionals of the quantile process. For example, the interquantile change \( \Gamma(\beta) = \beta(.75) - \beta(.25) \) or the Average Response \( \Gamma(\beta) = \int_{\tau_1}^{\tau_2} \beta(\tau) d\tau \), for \( 0 < \tau_1 < \tau_2 < 1 \).

We may estimate the weighted Aggregate Response \( \int_0^1 \beta_\phi(\tau) d\tau \) over the entire quantile range [0, 1] by trimming on the quantile levels such that \( [\epsilon, 1 - \epsilon] \) expands to [0, 1]. Specifically, it is sufficient to let \( \epsilon = \epsilon_n = o(n^{-1/2}) \).\(^8\) This result may be applicable to the first-price auctions in Marmer and Shneyerov (2012).

**Remark 4** (Alternative small bandwidth asymptotics and bootstrap). There are recently developed resampling methods for two-step semiparametric estimators. Cattaneo and Jansson (2018) develop an alternative asymptotic theory to the conventional empirical process theory that relies on the usual stochastic equicontinuity condition and is used in this paper. They allow for low precision of the first-step kernel-based estimators due to a small bandwidth and account for the resulting undersmoothing bias. They show that some nonparametric bootstrap methods automatically correct for such bias. In our simulation study, we examine the robustness of the nonparametric bootstrap as well as our normal distributional approximation, with respect to bandwidth choice.

### 4.3. Asymptotic Covariance Matrix

An asymptotically pivotal test statistic, a CI, or the corresponding hypothesis test can be constructed by a studentized version of the estimator using Slusky’s theorem with a consistent covariance matrix estimator. The covariance matrix could be consistently estimated as the sample variance of uniformly consistent estimators of the influence function. We provide a covariance matrix estimator that is composed of preliminary estimators already used in the primary AQD estimator. So we do not need additional estimation for the asymptotic covariance, such as estimating the derivative of the CQF \( \nabla Q(\tau | X_i) \).

\(^8\)Note that the minimum and maximum of the quantile levels \( \epsilon \) and \( 1 - \epsilon \) do not enter the uniform convergence rate of the remainder term in the Bahadur representation in (9). The condition for the convergence rate of \( \epsilon \) only depends on the tail distributions by \( \int_{(0, \epsilon) \cup (1 - \epsilon, 1)} \epsilon \| Q(\tau | X) \phi(X) \| \phi(X) d\tau = o_p(n^{-1/2}) \). Thus, assuming uniform bounded \( Q(\tau | X) \phi(X) \), it suffices to let \( \epsilon = \epsilon_n = o(n^{-1/2}) \).
We utilize the projection structure of the \( U \)-statistic, following Härdle and Stoker (1989) for the AMD. Define

\[
\hat{r}_f(\tau) = \frac{\hat{\phi}(X_i)}{\hat{f}_r(\hat{Q}(\tau | X_i))} \left( \mathbb{1}\{Y_i \leq \hat{Q}(\tau | X_i)\} - \tau \right) \mathbb{1}\{X_i \in \hat{S}\},
\]

\[
\hat{r}_w(\tau) = -\frac{1}{n-1} \sum_{j \neq i}^{1} \frac{1}{h_{i}^{d+1}} \nabla K(H^{-1}(X_i - X_j)) \times \left( \hat{\psi}(X_i; \tau) - \hat{\psi}(X_j; \tau) \right) \mathbb{1}\{X_j \in \hat{S}\} \mathbb{1}\{X_i \in \hat{S}\},
\]

where \( \hat{\phi}(X_i), \hat{\psi}(X_i; \tau), \text{ and } \hat{\gamma}(X_i; \tau) \) are defined specifically for \( \hat{\beta}_f \) and \( \hat{\beta}_w \) as follows.

We estimate the asymptotic covariance of \( \hat{\beta}_f \) by

\[
\text{Cov} (\hat{G}_f(\tau_1), \hat{G}_f(\tau_2)) = \frac{1}{n} \sum_{i=1}^{n} \hat{r}_f(Z_i; \tau_1) \hat{r}_f(Z_i; \tau_2)' - \bar{r}(\tau_1) \bar{r}(\tau_2)',
\]

for \( \tau_1 \leq \tau_2 \in \mathcal{T} \), where \( \hat{r}_f(Z_i; \tau) = \hat{r}_f(\tau) + \hat{r}_w(\tau) - \hat{\beta}_f(\tau), \) \( \bar{r}(\tau) = n^{-1} \sum_{i=1}^{n} \hat{r}_f(Z_i; \tau), \) and letting \( \hat{\phi}(X) = 2\hat{\psi}(X) \) in \( \hat{r}_f(\tau) \) and \( \hat{\psi}(X; \tau) = 2\hat{Q}(\tau | X) \) in \( \hat{r}_w(\tau) \).

We estimate the asymptotic covariance of \( \hat{\beta}_w \) by

\[
\text{Cov} (\hat{G}_w(\tau_1), \hat{G}_w(\tau_2)) = \frac{1}{n} \sum_{i=1}^{n} \hat{r}_w(Z_i; \tau_1) \hat{r}_w(Z_i; \tau_2)' - \bar{r}_w(\tau_1) \bar{r}_w(\tau_2)',
\]

where \( \hat{r}_w(Z_i; \tau) = \hat{r}_w(\tau) + \hat{\gamma}(\tau) - \hat{\beta}_w(\tau), \) \( \bar{r}_w(\tau) = n^{-1} \sum_{i=1}^{n} \hat{r}_w(Z_i; \tau), \) and letting \( \hat{\phi}(X) = \nabla (W(X)^\tau(X)) / \hat{f}(X) \) in \( \hat{r}_w(\tau) \), \( \hat{\psi}(X; \tau) = \hat{Q}(\tau | X) W(X) / \hat{f}(X) \) in \( \hat{r}_w(\tau) \), and \( \hat{\gamma}(X; \tau) = \hat{Q}(\tau | X) W(X) \nabla f(X) / \hat{f}(X)^2 \) in \( \hat{r}_w(\tau) \). These preliminary estimators of \( f(X_i), \nabla f(X_i), Q(\tau | X_i), \) and \( f_f(Q(\tau | X_i) | X_i) \) are already used in the primary estimators, so we do not need additional estimation.

**THEOREM 6.** Let Assumptions 1-4 hold. Then, for any \( \tau_1 \leq \tau_2 \in \mathcal{T} \), \( \text{Cov} (\hat{G}_f(\tau_1), \hat{G}_f(\tau_2)) \) and \( \text{Cov} (\hat{G}_w(\tau_1), \hat{G}_w(\tau_2)) \) are consistent for \( \text{Cov}(G_f(\tau_1), G_f(\tau_2)) \) and \( \text{Cov}(G_w(\tau_1), G_w(\tau_2)) \), respectively.

The influence function of the scaled AQD estimator \( \hat{\beta}_s \equiv \hat{\beta}_f / \hat{\alpha} \) with \( \hat{\alpha} = n^{-1} \sum_{i=1}^{n} \hat{f}(X_i) \) can be estimated by \( \hat{r}_{si}(\tau) = (\hat{r}_f(Z_i; \tau) - 2(\hat{f}(X_i) - \hat{\alpha}) \hat{\beta}_s(\tau)) / \hat{\alpha} \).

Then, the asymptotic covariance matrix of the scaled AQD estimator can be estimated by \( n^{-1} \sum_{i=1}^{n} \hat{r}_{si}(\tau) \hat{r}_{si}(\tau)' - \hat{r}_s(\tau) \hat{r}_s(\tau)' / n \), where \( \hat{r}_s(\tau) = n^{-1} \sum_{i=1}^{n} \hat{r}_{si}(\tau) \), for any \( \tau_1 \leq \tau_2 \in \mathcal{T} \).
4.4. Optimal Bandwidth Choice

We consider a linear combination of the density-weighted AQD $a' \hat{\beta}_f$, where $a \in \mathbb{R}^d$ and $a'a = 1$. For example, when $a = (1, 0, \ldots, 0)'$, $a' \hat{\beta}_f$ estimates the density-weighted AQD with respect to the first component of $X_i$. We modify the estimator proposed by Powell and Stoker (1996) for the optimal bandwidth $h$ in $K$ that minimizes the leading terms of the asymptotic MSE of $a' \hat{\beta}_f$. We can apply this approach for $\hat{\beta}_\phi$ and $\hat{\beta}_W$. We may also extend this approach to choose the trimming parameter $\delta$ and $h_0$.

The optimal bandwidth of $a' \hat{\beta}_f$ is estimated by $\hat{h}_\text{opt} = \left(d\hat{V}/( v \hat{B}) \right)^{1/(2v+d)} n^{-2/(2v+d)}$, where $\hat{V}$ estimates the leading variance associated with the bandwidth $h$ and $\hat{B}$ estimates the leading bias. As the first-order variance of $\hat{\beta}_f$ is $O(n^{-1/2})$, by choosing this optimal bandwidth $h_{\text{opt}}$, the bias is first-order asymptotically negligible. In addition, the first-step estimators are undersmoothed.

Define $\hat{V} = h_v^d (n(n-1))^{-1} \sum_{i=1}^n \sum_{j \neq i} \hat{p}(Z_i,Z; \lambda)^2$, where
\[
\hat{p}(Z_i,Z; \lambda) \equiv \left( \hat{Q}(\tau|X) - \hat{Q}(\tau|X_i) \right) a' \nabla K \left( \frac{X_i - X_j}{h_v} \right) h_v^{-(d+1)} 1_i \nonumber \\
- K(\hat{H}_v^{-1}(X_i - X_j)) h_v^{-d} 1_i \nonumber \\
\times \left( \frac{a' \nabla \hat{f}(X_i)}{\hat{f}_{XY}(X_i, \hat{Q}(\tau|X_i))} \left( \tau - G \left( \frac{\hat{Q}(\tau|X_i) - Y_j}{h_0} \right) \right) \right) \nonumber \\
+ \frac{a' \nabla \hat{f}(X_i)}{\hat{f}_{XY}(X_j, \hat{Q}(\tau|X_j))} \left( \tau - G \left( \frac{\hat{Q}(\tau|X_j) - Y_i}{h_0} \right) \right) \nonumber 
\]
and the preliminary estimators $\hat{Q}(\tau|X)$, $\nabla \hat{f}(X)$, and $\hat{f}_{XY}$ use a $v$th-order kernel with bandwidth $h = h_1 = h_v$. We consider a fixed trimming function $1_i$ with a constant $\delta$, to simplify the application of the results in Powell and Stoker (1996).

Consider estimating the leading bias of $\hat{\beta}_f$. For a positive constant $u \neq 1$ and a preliminary bandwidth $h = h_1 = h_b$, let $\hat{\beta}_{f,b}$ and $\hat{\beta}_{f,uhb}$ be the estimators using the bandwidths $h_b$ and $uh_b$, respectively. Let $v = v_1$ for simplicity. Define $\tilde{B} = a'(\hat{\beta}_{f,uhb} - \hat{\beta}_{f,b})/(\text{tr}(uh_b)^v - h_b^v)$.

**COROLLARY 1.** Let the conditions in Theorem 4 hold.

(i) Then, the bandwidth that minimizes the leading terms associated with $h$ in the asymptotic MSE of $\hat{\beta}_f$ is $h_{\text{opt}} = \left(d\hat{V}/( v \hat{B}) \right)^{1/(2v+d)} n^{-2/(2v+d)}$, where
\[
\hat{V} = \int \mathbb{E}\left[ (\nabla Q(\tau|X)) \nabla^2 f(X) \right] (a' \nabla K(u))^2 du + 2\tau (1 - \tau) \mathbb{E}\left[ (a' \nabla f(X))^2 f(X) f_{XY} (X, Q(\tau|X))^{-2} \right] \int K(u)^2 du \quad \text{with } u \in \mathbb{R}^d, \quad \text{and} \quad \hat{B} = 2\kappa_v \sum_{k=1}^d a_k \mathbb{E}\left[ \partial f(X) f_{XY} (X, Q(\tau|X))^{-1} \sum_{i=1}^n (l!(\nu - l)!)^{-1} \partial^k f_Y(Q(\tau|X)|X) \partial_k f(X) - (\nu - 1) Q(\tau|X) \right].
\]

(ii) Furthermore, let $h_v, h_b \to 0$, $nh_v^d \to \infty$, and $nh_b^{2v+d} \to \infty$. Then, $\hat{V}$ and $\tilde{B}$ are consistent estimators of $V$ and $\tilde{B}$, respectively, and $h_{\text{opt}} - h_{\text{opt}} = O_p(n^{-2/(2v+d)})$.

We may consider a further bias correction using the above simple bias estimator, i.e., $\hat{\beta}_f - h\hat{\mathcal{B}}$. Such robust bias-corrected inference may allow for a wider range of bandwidth choices $h$ in practice, as discussed in Calonico, Cattaneo, and Farrell (2018), and is left for future research.

5. MONTE CARLO SIMULATIONS

We compare the finite-sample performance of our scaled density-weighted AQD estimator $\hat{\beta}_s$ with the AMD in Powell et al. (1989), the conventional Koenker and Bassett (1978) linear QR (labeled by KB), and the OLS. We consider partially linear models with homogenous and heterogenous errors for the DGPs. Both AMD and AQD identify the coefficient of interest in the partially linear model. The linear OLS and KB estimators suffer from misspecification. We find that the scaled

![Figure 1. Partially linear model with $\mathcal{N}(0,1)$ error.](https://example.com/figure1.png)
density-weighted AQD estimator \( \hat{\beta}_s \) outperforms the AMD when the outcome distribution has fat tails. The results are rather robust with a range of bandwidths. We consider four DGPs that are modified from the experiments in Lee (2003).

1. Partially linear model with homoscedastic error (PL-homo):
   \[ Y = X_1 + X_2 + 30\exp(-X_1^2)/\sqrt{2\pi} + e. \]

2. Partially linear model with heteroskedastic error (PL-hetero):
   \[ Y = X_1 + X_2 + 30\exp(-X_1^2)/\sqrt{2\pi} + 2\exp((X_1 + X_2)/4)e. \]

We consider two error distributions: \( e \sim N(0, 1) \) and \( e \sim t(2) \) for a fat-tailed distribution. The regressors \( X_1 \) and \( X_2 \) are jointly normal with mean zero, variance one, and covariance 0.5. Thus, the regressors have unbounded support. The parameter of interest is the coefficient of \( X_2 \), i.e., the true parameter is 1.

**Figure 2.** Partially linear model with \( t(2) \) error.
TABLE 1. (PL-hetero-N(0,1): \( n = 500, 500 \) bootstrap samples, \( 500 \) replications for each experiment) The bandwidth \( h = C\sigma_x 500^{-0.15} \), where \( \sigma_x \) is the interquantile range of \( X_2 \). The first row reports the simulation bias relative to simulation standard error. The second row reports the simulation MSE. The next four rows report the coverage rates of the Normal, Symmetric, Percentile, and Efron 95% CIs, respectively. The top panel is for the results of AQD, and the bottom panel is for AMD.

| Bandwidth constant | C | 1.5 | 2 | 2.5 | 3 | 3.5 | 4 |
|--------------------|---|-----|---|-----|---|-----|---|
| AQD BIAS/SE        | -0.220 | -0.171 | -0.180 | -0.323 | -0.606 | -1.043 |
| MSE                | 0.051 | 0.040 | 0.039 | 0.040 | 0.045 | 0.058 |
| Normal             | 0.990 | 0.972 | 0.962 | 0.952 | 0.936 | 0.854 |
| Symmetric          | 0.990 | 0.978 | 0.966 | 0.956 | 0.938 | 0.852 |
| Percentile         | 0.986 | 0.974 | 0.960 | 0.950 | 0.920 | 0.842 |
| Efron              | 0.980 | 0.966 | 0.952 | 0.950 | 0.938 | 0.852 |
| AMD BIAS/SE        | 0.075 | 0.042 | -0.020 | -0.064 | -0.173 | -0.315 |
| MSE                | 0.052 | 0.036 | 0.031 | 0.029 | 0.029 | 0.030 |
| Normal             | 0.996 | 0.976 | 0.974 | 0.966 | 0.964 | 0.952 |
| Symmetric          | 0.996 | 0.978 | 0.974 | 0.972 | 0.962 | 0.956 |
| Percentile         | 0.994 | 0.978 | 0.970 | 0.968 | 0.956 | 0.956 |
| Efron              | 0.984 | 0.968 | 0.964 | 0.962 | 0.960 | 0.948 |

We use the fourth-order Epanechnikov kernel. Under Assumption 3, we choose the trimming bound \( \delta \propto n^{-0.02} \) and trim 5% of the sample at the tails. The bandwidths are \( h_1 = h = C\sigma_x n^{-0.15} \) and \( h_0 = C\sigma_y n^{-0.3} \), where the powers satisfy Assumption 3, and \( \sigma_x \) and \( \sigma_y \) are the interquantile range of \( X \) and \( Y \), respectively (Silverman, 1986). Figures 1 and 2 report the MSEs against a range of \( C \). There are 1,000 replications in each experiment. We compute the optimal bandwidth \( h_{opt} \) for (0, 1) \( \tilde{\beta}_f \) proposed in Section 4.4 as a reference bandwidth. For the DGP PL-hetero-N(0,1), the corresponding optimal constant \( C = 2.39 \) for \( n = 200 \) and \( C = 1.76 \) for \( n = 500 \). The theoretical optimal bandwidth that minimizes the MSE appears to agree with the simulation results in the lower panel of Figure 1.

For the normal error in Figure 1, AMD and AQD outperform the linear estimators, OLS and KB. For the fat-tailed error in Figure 2, the QRs (AQD and KB) outperform the mean regressions (AMD and OLS). The optimal bandwidth that minimizes the MSE for the AQD is smaller than that of the AMD. This is because AQD involves additional nonparametric estimation of the CQF, and the nonparametric estimator is more undersmoothed. When the bandwidth is around

---

Footnote 9: Specifically, we numerically compute \( \tilde{V} \) described in Section 4.4 with a preliminary bandwidth \( h = 3.12\sigma_x n^{-0.15} \), where 3.12 is from the Silverman rule-of-thumb bandwidth and \( n = 5,000 \). For \( \tilde{B} \), we choose \( u = 0.5 \) and \( h_b = 3.12\sigma_x n^{-0.07} \). The conditions in Corollary 1 hold.
the MSE optimal bandwidth, the nonparametric estimators perform well in finite samples. Overall, AQD outperforms the linear KB.

Table 1 reports the coverage rates of three bootstrap-based CIs, following the definitions in Cattaneo and Jansson (2018). In standard notation, the superscript * denotes the bootstrap analog computed under the bootstrap distribution conditional on the data. Let $q_{n,\alpha}^* = \inf\{q \in \mathcal{R} : P^*[\hat{\beta}_s - \hat{\beta}_s \leq q] \leq \alpha\}$ and $Q_{n,\alpha}^* = \inf\{Q \in \mathcal{R} : P^*[|\hat{\beta}_s - \hat{\beta}_s| \leq Q] \leq \alpha\}$. Then, Efron CI = $[\hat{\beta}_s + q_{n,\alpha/2}^*, \hat{\beta}_s + q_{n,1-\alpha/2}^*]$, Percentile CI = $[\hat{\beta}_s - q_{n,1-\alpha/2}^*, \hat{\beta}_s + q_{n,\alpha/2}^*]$, and Symmetric CI = $[\hat{\beta}_s - Q_{n,1-\alpha}^*, \hat{\beta}_s + Q_{n,1-\alpha}^*]$. We also consider Normal CI = $[\hat{\beta}_s - \hat{q}_{n,1-\alpha/2}^*, \hat{\beta}_s + \hat{q}_{n,\alpha/2}^*]$, where $\hat{q}_{n,\alpha} = \Phi^{-1}(\alpha)se$, $\Phi$ is the standard normal CDF, and we use the bootstrap standard error of $\hat{\beta}_s$ for $se$. The simulation results are mostly in line with the theoretical findings in Cattaneo and Jansson (2018) and this paper. For most cases, Symmetric CI has the largest coverage rates, whereas the Efron CI has the smallest coverage rates, as predicted by Cattaneo and Jansson (2018). Normal CI is comparable with the bootstrap-based CIs, and all inference procedures perform reasonably. One possible explanation of this result is that the small-bandwidth bias studied in Cattaneo and Jansson (2018) is relatively small in this DGP.

6. CONCLUSION AND OUTLOOK

We estimate weighted AQDs via a weighted average CQF. We show that our estimators are asymptotic linear uniformly over the quantile index and converge weakly to Gaussian processes. We also characterize the leading bias. More generally, this paper is concerned with one of the semiparametric estimation problems based on a preliminary nonparametric estimator and involving a stochastic trimming function. We demonstrate a novel application of the uniform convergence results of nonparametric kernel-based estimators on expanding interior supports in Hansen (2008) and Cattaneo et al. (2013), so that our asymptotic analysis is tractable for the stochastic trimming problem.

There are several important directions for future research. The criteria of choosing the bandwidths and trimming parameter for finite samples are to be investigated. For the AMD, Cattaneo et al. (2010, 2013, 2014a, 2014b) and Cattaneo and Jansson (2018) develop several methods for robust inference in terms of the bandwidth choice. There is recent development on the trimming parameter for the inverse probability weighting estimator of treatment effects, e.g., Ma and Wang (2019) and Sasaki and Ura (2021) propose inference methods that account for the trimming bias. Since our estimands are more complex, estimating the

\[10\text{For example, Cattaneo et al. (2013) propose a generalized Jackknife estimator for the unweighted AMD, where the first-step estimator enters the m-estimator nonlinearly. They correct for the nonlinear bias and characterize a quadratic expansion. Consequently, they assume weaker-than-usual conditions on moments, bandwidths, and kernel order. Our first-step estimators } f(X) \text{ and } F_Y(y|X) \text{ enter the weighted AQD nonlinearly, and we characterize their biases. However, the quadratic expansion is more complicated in our problem due to the CQF estimation.} \]
trading bias and a data-driven trimming parameter are out of the scope of this paper and left for future research. As with the rich literature of the AMD, more theoretical and empirical research on the AQD could be expected.

**APPENDIX**

The Appendix is organized as follows. We first state the notations and assumptions. Then, we present preliminary lemmas, whose proofs are in Appendix C. The asymptotic theorems for the weighted AQD estimator $\hat{\beta}$ are first derived for the infeasible estimator $\hat{\beta} \equiv -n^{-1} \sum_{i=1}^n \hat{Q}(\tau | X_i) \phi(X_i) 1\{X_i \in S\}$, trimmed based on the true density. Then, Lemma 4 shows $\sqrt{n}(\hat{\beta} - \beta) = o_p(1)$ uniformly over $\tau$. Appendix A.1 presents the proofs of Theorems 1 and 2. Appendix B presents the proofs of Theorems 3–6.

Notations. Let $Z = (X', Y)', f_{Y|X}(y|x)$ denotes the derivative with respect to $y$ that should not be confusing with the transpose of a matrix $A'$. $C$ denotes a generic constant. For an $m \times n$ matrix $A$, we use Frobenius norm: $\|A\| = \text{trace}(AA')^{1/2}$. Let $\|f\|_\infty$ be the sup-norm for a function, i.e., $\|f\|_\infty = \sup_{x \in \mathcal{X}} |f(x)|$. $s.o.$ denotes smaller-order terms. $w.p.a.1$ means with probability approaching one. Denote the product of two functions $A(X)$ and $B(X)$ by $A(\cdot)B(\cdot)(X) \equiv (AB)(X) \equiv A(X)B(X)$. For simplicity, $Q_i = Q(\tau | X_i)$, $G_{ij} \equiv G(\frac{Q(\tau | X_i - Y_j)}{h_0})$, $K_{ij} \equiv K(H^{-1}(X_i - X_j))$, $f_i = f(X_i)$, and $I_i \equiv 1\{X_i \in S\}$. For some notations in the following proof, we omit $\tau$ and $X$ for brevity without loss of clarity; for example, $Q \equiv Q(\tau | x)$ and $Q \equiv Q(\tau | x)$.

**LEMMA 1** (Uniform convergence rate). Let Assumptions 1 and 2 hold with $p_x \geq v$. Define $C_n \equiv \{x : \|x\| \leq c_n\}$, where $c_n$ satisfies $\limsup_{n \to \infty} \log(c_n)/\log n < \infty$.

1. Define $\delta = \delta_n \equiv \inf_{x \in C_n} f(x)$. Let $\delta^{-1} \left( \sqrt{\log n / (nh^d)} + h_0^2 + h^v \right) \to 0$. Then,

$$\sup_{x \in C_n, y \in \mathcal{Y}} \left| \hat{F}_Y(y|x) - F_Y(y|x) \right| = O_p \left( \frac{1}{\delta} \left( \sqrt{\frac{\log n}{nh^d}} + h_0^2 + h^v \right) \right).$$

2. Define $\mathcal{Y}_n \equiv \{\|y\| \leq c_n\}$ and $\delta = \delta_n \equiv \inf_{x \in C_n, y \in \mathcal{Y}_n} f_{XY}(x, y)$. Let $\delta^{-1} \left( \sqrt{\log n / (nh^d h_0^2)} + h_0^2 + h^v \right) \to 0$. Then,

$$\sup_{x \in C_n, y \in \mathcal{Y}_n} \left| \frac{\partial}{\partial y} \hat{F}_Y(y|x) - f_Y(y|x) \right| = O_p \left( \frac{1}{\delta} \left( \sqrt{\frac{\log n}{nh^d h_0^2}} + h_0^2 + h^v \right) \right).$$

**LEMMA 2.** Let Assumption 1 and 2 hold with $p_x \geq v_1 + 2$. For a measurable function $\psi : \mathcal{X} \times T \mapsto \mathcal{R}$, assume the $(v_1 + 1)\text{th}$-order derivative of $\psi(x; \tau)$ with respect to $x$ to be uniformly continuous and bounded, for any $x \in \mathcal{S}$ and $\tau \in T$. Assume $\{X \mapsto \psi(X; \tau) : \tau \in T\}$ to be euclidean and $\mathbb{E}\left[ \left( \sup_{\tau \in T} \psi(X; \tau) \right)^2 \right] < \infty$. Let $nh_1^{2d+2} \to \infty$ and $\sqrt{nh_1^{v_1}} \to c \in [0, \infty)$. Then, uniformly in $\tau \in T$,

$$\frac{1}{\sqrt{n}} \sum_{i=1}^n \left( \psi(X_i; \tau) \nabla \hat{f}(X_i) I\{X_i \in S\} - \mathbb{E}\left[ \psi(X; \tau) \nabla f(X) \right] - \text{Bias}_\psi (X_i; \tau) \right).$$
\[
\frac{1}{\sqrt{n}} \sum_{i=1}^{n} \left( -f(X_i) \nabla \psi(X_i; \tau) + \mathbb{E}[f(X) \nabla \psi(X; \tau)] \right) + o_p(1), \text{ where}
\]

\[
\text{Bias}_\psi(X; \tau) \equiv \frac{h_1^{v_1} \kappa_{v_1}}{v_1} \sum_{k=1}^{d} \mathbb{E}[\psi(X; \tau) \partial_k^v \nabla f(X)].
\]

**Lemma 3.** Let Assumptions 1 and 2 hold with \( p_x \geq v_1 + 1 \). For a measurable function \( \gamma : X \times T \mapsto \mathcal{R} \), assume the \((v_1 + 1)\)th-order derivative of \( \gamma(x; \tau) \) with respect to \( x \) to be uniformly continuous and bounded, for any \( x \in S \) and \( \tau \in T \). Assume \( \{X \mapsto \gamma(X; \tau) : \tau \in T\} \) to be euclidean and \( \mathbb{E} \left[ (\sup_{\tau \in T} \gamma(X; \tau))^2 \right] < \infty \). Let \( nh_1^{2d} \to \infty \) and \( \sqrt{nh_1^v} \to c \in [0, \infty) \). Then, uniformly in \( \tau \in T \),

\[
\frac{1}{\sqrt{n}} \sum_{i=1}^{n} \left( \gamma(X_i; \tau) (\hat{f}(X_i) - f(X_i)) 1\{X_i \in S\} - \text{Bias}_\gamma(X; \tau) \right)
\]

\[
= \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \left( \gamma(X_i; \tau) f(X_i) - \mathbb{E}[\gamma(X; \tau) f(X)] \right) + o_p(1), \text{ where}
\]

\[
\text{Bias}_\gamma(X; \tau) \equiv \frac{h_1^{v_1} \kappa_{v_1}}{v_1} \sum_{k=1}^{d} \mathbb{E}[\gamma(X; \tau) \partial_k^v f(X)].
\]

**Lemma 4 (Trimming).** Let all assumptions in Theorem 3 hold. Let \( \sup_{x \in S, \tau \in T} |\hat{\phi}(x; \tau) - \phi(x; \tau)| = o_p(1) \). Then, \( n^{-1/2} \sum_{i=1}^{n} \hat{\phi}(X_i; \tau) \left( 1\{X_i \in \hat{S}\} - 1\{X_i \in S\} \right) = o_p(1) \) uniformly in \( \tau \in T \).

**Lemma 5.** Let the conditions in Theorem 3 hold. Denote \( p(Z_i, Z_j; \lambda) = \frac{\phi_i}{f_i f_j (Q_i | X_i)} \frac{1}{|T|} \kappa_{ij} (\tau - G_{ij}) \). Then,

\[
\mathbb{E}\left[ p(Z_i, Z_j; \lambda) | Z_i \right] = \frac{-\phi_i}{f_i f_j (Q_i | X_i)} \left\{ h^v \kappa_v \sum_{l=1}^{v} \frac{1}{l! (v-l)!} \sum_{k=1}^{d} \partial_k^v f_Y(Q_i | X_i) \partial_k^{v-l} f(X_i) \right.
\]

\[
+ \frac{h^2}{2} \kappa_{G2} f_Y(Q_i | X_i) f_i \right. - h^v h^2_0 R_f(X_i) + O(h^{v+1} + h^3_0) \right\},
\]

where \( R_f(X_i) = \frac{\kappa_{G2}}{2} \kappa_v \sum_{l=0}^{v} \frac{1}{l! (v-l)!} \sum_{k=1}^{d} \partial_k^v f_Y(Q_i | X_i) \partial_k^{v-l} f(X_i) \). In addition,

\[
\mathbb{E}\left[ \frac{1}{n(n-1)} \sum_{i=1}^{n} \sum_{j \neq i} p(Z_i, Z_j; \lambda) \right]
\]

\[
= -\mathbb{E}\left[ \frac{\phi_i}{f_i f_j (Q_i | X_i)} \left( h^v \kappa_v \sum_{l=1}^{v} \frac{1}{l! (v-l)!} \sum_{k=1}^{d} \partial_k^v f_Y(Q_i | X_i) \partial_k^{v-l} f(X_i) + \frac{h^2}{2} \kappa_{G2} f_Y(Q_i | X_i) f_i \right) \right.
\]

\[
+ h^v h^2_0 R_f(X_i) \right] + o(h^v + h^3_0).
\]
A. Proofs of Theorems 1 and 2 in Section 4.1

Proof of Theorem 1. The proofs use the following preliminary results (i) and (ii). Suppose that, for any \( x \in \mathcal{S} \), there exists a compact convex set \( \mathcal{Y}_x \equiv [\mathcal{Q}(\varepsilon|x), \mathcal{Q}(1-\varepsilon|x)] \subset \mathcal{Y} \) such that \( \inf_{x \in \mathcal{S}} \inf_{y \in \mathcal{Y}_x} f_{XY}(x,y) \geq \delta \).

(i) \( \hat{Q}(\tau|x) \in [\mathcal{Q}(\varepsilon|x), \mathcal{Q}(1-\varepsilon|x)] = \mathcal{Y}_x \) w.p.a.1, for any \( x \in \mathcal{S} \) and \( \tau \in \mathcal{T} \).

(ii) \( \sup_{x \in \mathcal{S}, \tau \in \mathcal{T}} \left( f_{XY}(x,\hat{Q}(\tau|x)) \right)^{-1} = O_p(\delta^{-1}) \).

To briefly discuss these results, Lemma 1 implies \( \eta \in (0, \min\{\tau - \varepsilon, 1 - \varepsilon - \tau\}) \) such that \( \sup_{\tau \in \mathcal{Y}_x} |\hat{F}_Y(\tau|x) - f_Y(\tau|x)| < \eta \), w.p.a.1. So \( \sup_{x \in \mathcal{S}, \tau \in \mathcal{T}} |\hat{F}_Y(\hat{Q}(\tau|x)|x) - f_Y(\hat{Q}(\tau|x)|x)| < \eta \), w.p.a.1. Since \( \hat{F}_Y(\hat{Q}(\tau|x)|x) = \tau \), we observe \( f_Y(\hat{Q}(\tau|x)|x) = \delta < \tau - \eta < f_Y(Q(\tau|x)|x) < \tau + \eta < 1 - \varepsilon = f_Y(Q(1-\varepsilon|x)|x) \). Monotonicity of \( f_Y(\tau|x) \) in \( y \) implies (i). Then, \( \inf_{\tau \in \mathcal{Y}_x} \{\hat{F}_Y(\hat{Q}(\tau|x)|x) \geq \delta \} \), w.p.a.1 that implies (ii). When \( \mathcal{Y}_x \) degenerates to a point, i.e., \( \mathcal{Q}(\tau|x) = \mathcal{Q}(\varepsilon|x) = \mathcal{Q}(1-\varepsilon|x) \), for \( \tau \in \mathcal{T} \), we modify (i) \( \hat{Q}(\tau|x) \xrightarrow{p} \mathcal{Q}(\varepsilon|x) \). Then (ii) follows.

Uniform convergence rate. For any \( x \in \mathcal{S} \) and \( \tau \in \mathcal{T} \), a Taylor series expansion yields \( F_Y(\hat{Q}(\tau|x)|x) = F_Y(\mathcal{Q}(\tau|x)|x) + f_Y(\hat{Q}(\tau|x)|x)(\hat{Q}(\tau|x) - \mathcal{Q}(\tau|x)) \), where \( \mathcal{Q}(\tau|x) \) is on the line segment between \( \mathcal{Q}(\tau|x) \) and \( \hat{Q}(\tau|x) \). We claim

\[
\sup_{\tau \in \mathcal{T}} \left| \hat{Q}(\tau|x) - \mathcal{Q}(\tau|x) \right| = \sup_{\tau \in \mathcal{T}} \sup_{x \in \mathcal{S}} \frac{|F_Y(\hat{Q}(\tau|x)|x) - f_Y(\mathcal{Q}(\tau|x)|x)|}{f_{XY}(x,\mathcal{Q}(\tau|x))} \leq O_p \left( \frac{1}{\delta} \sup_{x \in \mathcal{S}} \left( |F_Y(\tau|x) - \hat{F}_Y(\tau|x)|f(x)| \right) \right) = O_p \left( \frac{1}{\delta} \left( \sqrt{\frac{\log n}{nh^d}} + h_0^2 + h^2 \right) \right)
\]

by the following reasons: For the numerator, \( \hat{F}_Y(\hat{Q}(\tau|x)|x) = \tau = F_Y(Q(\tau|x)|x) \) by construction. Then, use the result for \( \Psi = F_Y(\tau|x)f(x) \) in Proof of Lemma 1(1). For the denominator, the above results (i) and (ii) imply \( \sup_{\tau \in \mathcal{T}} \left( f_{XY}(x,\hat{Q}(\tau|x)) \right)^{-1} = O_p(\delta^{-1}) \).

Bahadur representation. Since \( \hat{F}_Y(\tau|x) \) is smooth in \( y \), we can expand \( \hat{F}_Y(\hat{Q}(\tau|x)|x) \) around \( \mathcal{Q}(\tau|x) \) by a Taylor series expansion, for any \( x \in \mathcal{S} \) and \( \tau \in \mathcal{T} \):

\[
\tau = \hat{F}_Y(\hat{Q}(\tau|x)|x) = \hat{F}_Y(\mathcal{Q}(\tau|x)|x) + \hat{f}_Y(\mathcal{Q}(\tau|x)|x)(\hat{Q}(\tau|x) - \mathcal{Q}(\tau|x)) + \frac{1}{2} \hat{f}_Y^2(\hat{Q}(\tau|x)|x)(\hat{Q}(\tau|x) - \mathcal{Q}(\tau|x))^2,
\]

where \( \mathcal{Q}(\tau|x) \) is on the line segment between \( \mathcal{Q}(\tau|x) \) and \( \hat{Q}(\tau|x) \). To simplify notations without loss of clarity, we sometimes omit \( \tau \) and \( x \), e.g., \( Q \equiv \mathcal{Q}(\tau|x) \). From (12),

\[
\hat{Q}(\tau|x) - \mathcal{Q}(\tau|x) = \frac{\tau - \hat{F}_Y(\mathcal{Q}(\tau|x)|x)}{\hat{f}_Y(\mathcal{Q}(\tau|x)|x)} + \left( \tau - \hat{F}_Y(\mathcal{Q}(\tau|x)|x) \right) \left( \frac{1}{\hat{f}_Y(\mathcal{Q}(\tau|x)|x)} - \frac{1}{f_Y(\mathcal{Q}(\tau|x)|x)} \right) - \frac{1}{2} \frac{\hat{f}_Y^2(\hat{Q}(\tau|x)|x)}{\hat{f}_Y(\mathcal{Q}(\tau|x)|x)}(\hat{Q}(\tau|x) - \mathcal{Q}(\tau|x))^2
\]

\[= \frac{A_{\tau}(x)}{f_{XY}(x,\mathcal{Q}(\tau|x))} \]
\[ + \frac{A_\tau(x)}{f_{XY}(x, Q)} \left( \frac{f(x) - \hat{f}(x)}{\hat{f}(x)} \right) + \frac{A_\tau(x)}{f_{XY}(x, Q)} \left( \frac{f_Y(Q(\tau|x)|x) - \hat{Y}(Q(\tau|x)|x)}{\hat{Y}(Q(\tau|x)|x)} \right) = B(x) \]

\[ + \frac{A_\tau(x)}{f_{XY}(x, Q)} B(x)C_\tau(x) - \frac{1}{2} \frac{\hat{Y}(Q(\tau|x)|x)}{\hat{Y}(Q(\tau|x)|x)} \left( \hat{Q}(\tau|x) - Q(\tau|x) \right)^2, \]

where \( A_\tau(x) = n^{-1} \sum_{j=1}^{n} K_h(x - x_j) \left( \tau - G \left( \frac{Q(\tau|x)|x - Y_j}{h_0} \right) \right) \). By Proof of Lemma 1(1), \( A_\tau(x) = \tau \left( \hat{f}(x) - f(x) \right) - \left( \hat{Q}(\tau|x,x) - \tau f(x) \right) \). So \( \sup_{x \in S, \tau \in T} |A_\tau(x)| = O_P \left( \sqrt{\frac{\log n}{nh\delta^2}} \right) \).

\[ C_\tau(x) = \frac{f_Y(Q|x) - \hat{f}_Y(Q|x)}{f_Y(Q|x)} + \left( \frac{f_Y(Q|x) - \hat{f}_Y(Q|x)}{f_Y(Q|x)} \right) \left( \frac{1}{\hat{f}_Y(Q|x)} - \frac{1}{f_Y(Q|x)} \right), \]

where the first leading term is

\[ \frac{f_{XY}(x, Q) - \hat{f}_{XY}(x, Q)}{f_{XY}(x, Q)} + \frac{\hat{f}_{XY}(x, Q)}{f_{XY}(x, Q)} \left( 1 - \frac{f(x)}{\hat{f}(x)} \right) \]

\[ = \frac{1}{f_{XY}(x, Q)} \left( f_{XY}(x, Q) - \hat{f}_{XY}(x, Q) \right) - B(x) + \left( \frac{\hat{f}_{XY}(x, Q)}{f_{XY}(x, Q)} - 1 \right) \left( 1 - \frac{f(x)}{\hat{f}(x)} \right) \]

\[ = O_P \left( \frac{1}{\delta} \left( \sqrt{\frac{\log n}{nh^d h_0}} + h_0^2 + h^\nu \right) \right) - B(x) \]

\[ + O_P \left( \frac{1}{\delta^2} \left( \sqrt{\frac{\log n}{nh^d h_0}} + h_0^2 + h^\nu \right) \left( \sqrt{\frac{\log n}{nh^d}} + h^\nu \right) \right) \]

by Lemma 1(2). So the leading term of \( A_\tau(x)(B(x) + C_\tau(x))/f_{XY}(x, Q) \) in (13) is

\[ O_P \left( \frac{1}{\delta^3} \left( \sqrt{\frac{\log n}{nh^d}} + h^\nu \right) \left( \sqrt{\frac{\log n}{nh^d h_0}} + h_0^2 + h^\nu \right) \right). \]

The last term in (14) is

\[ \sup_{x \in S, \tau \in T} \left| -\frac{1}{2} \frac{\hat{Y}(Q(\tau|x)|x)}{\hat{Y}(Q(\tau|x)|x)} \left( \hat{Q}(\tau|x) - Q(\tau|x) \right)^2 \right| \leq O_P \left( \frac{1}{\delta^3} \left( \sqrt{\frac{\log n}{nh^d}} + h_0^2 + h^\nu \right) \right)^2 \]

by the following reasons: First, the result (ii) and Assumption 1 imply \( f_Y(\hat{Q}(\tau|x)|x) \) is uniformly bounded w.p.a.1. Second, for any \( \varepsilon > 0 \), there is a constant \( c_f \) such that

\[ |f_{XY}(x, Q(\tau|x)) - f_{XY}(x, Q(\tau|x))|_{1 \in S, \tau \in T} \leq c_f \left( n^{1-\varepsilon} h_0 h^d \right)^{-1/2} + h_0^2 + h^\nu \equiv c_{2n}, \]

w.p.a.1. So \( \inf_{x \in S, \tau \in T} f_{XY}(x, Q(\tau|x)) \geq \delta - c_{2n}, \) w.p.a.1. We obtain the bound of \( R_n \) in (10) by collecting the remainder terms (15) and (16).
within rows. Define the $n \times 1$ vector $f_n(\omega, \tau) \equiv (f_{n1}(\omega, \tau), \ldots, f_{nm}(\omega, \tau))^\top$ and the random set $\mathcal{F}_{n0} \equiv \{ f_n(\omega, \tau) : \tau \in \mathcal{T} \}$. In the following, we check the conditions (i)–(v) for the functional CLT, Theorem 10.6 in Pollard (1990).

(i) The triangular array processes $\{ f_{ni}(\omega, \tau) \}$ are manageable with respect to the envelopes $\mathcal{F}_{ni}(\omega) \equiv \delta^{-1}(nh^n)^{-1/2}K(H^{-1}(X_i(\omega) - x))$. First, $\{ X \mapsto f_Y(Q(\tau|X)|X) : \tau \in \mathcal{T} \}$ and $\{ (X, Y) \mapsto G((Q(\tau|X - Y)/h_0) : \tau \in \mathcal{T} \}$ are euclidean and manageable by Lemma 2.13 and Example 2.10 in Pakes and Pollard (1989) and p. 221 in Kosorok (2008). In addition, $\mathcal{F}_{n}(\omega) \equiv (F_{n1}, \ldots, F_{nm})^\top$ is an $\mathcal{R}_n$-valued function on the underlying probability space. Then (i) is proved by applying Lemma E1 in Andrews and Shi (2013).

We first calculate the following results. As $h_0 \to 0$,

$$
\mathbb{E} \left[ G(\frac{Q(\tau|X_i) - Y_j}{h_0}) \right]_{X_i, X_j} = G(\frac{Q_i - \bar{Y}}{h_0}) + \int_{\mathcal{V}} g(v) F_Y(Q_i - h_0v|X_j) dv + \int_{-\infty}^{\infty} g(v) \left( F_Y(Q_i|V_j) - h_0vf_Y(Q_i|X_j) + \frac{h_0^2}{2}v^2f'_Y(Q_i|X_j) + \frac{h_0^3}{3!}v^3f''_Y(Q_i|X_j) \right) dv
$$

$$
- \int_{\mathcal{V} \setminus \mathcal{V}} g(v) \left( F_Y(Q_i|X_j) - h_0vf_Y(Q_i|X_j) + \frac{h_0^2}{2}v^2f'_Y(Q_i|X_j) + \frac{h_0^3}{3!}v^3f''_Y(Q_i|X_j) \right) dv
$$

$$
= F_Y(Q_i|X_j) + \frac{h_0^2}{2}f'_Y(Q_i|X_j)\kappa_{G2} + O(h_0^3),
$$

where $\mathcal{V} \equiv \left[ \frac{Q_i - \bar{Y}}{h_0}, \frac{Q_i - \bar{Y}}{h_0} \right]$. The second equality is a Taylor series expansion around $Q_i$, and $\bar{Q}_i$ is on the line segment between $Q_i$ and $Q_i - h_0v$. When $g$ has a bounded support, $G(z/h_0)$ is zero for a small enough $h_0$ and for any negative $z$. Thus, when $g$ has a bounded support or when the support of $Y$ is $\mathcal{R}$, i.e., $\mathcal{V} = \mathcal{R}$, the term (17) is zero for a small enough $h_0$. When $\bar{y}$ or $y$ is bounded and $g$ has an unbounded support, Assumption 2(G) implies that $G(z/h_0) \equiv o(h_0^3)$, for any $z < 0$. Thus, the first term of (17) is $-F_Y(Q_i|X_j) \left( 1 - G\left( \frac{Q_i - \bar{Y}}{h_0} \right) \right)$.

Similarly, the second and third terms are $o(h_0^3)$ by integration by parts. The last term of (17) is $O(h_0^3)$ by the uniform continuity of $f'_Y(y|X)$ in $y$ and the dominated convergence theorem.

By a similar argument, for $q_1 \leq q_2$,

$$
\mathbb{E} \left[ G\left( \frac{q_1 - Y}{h_0} \right) G\left( \frac{q_2 - Y}{h_0} \right) \right]_{X} = \int_{\mathcal{V}} \left( \frac{1}{h_0} g\left( \frac{q_1 - y}{h_0} \right) G\left( \frac{q_2 - y}{h_0} \right) + \frac{1}{h_0} g\left( \frac{q_1 - y}{h_0} \right) G\left( \frac{q_1 - y}{h_0} \right) \right) F_Y(y|X) dy + G\left( \frac{q_1 - y}{h_0} \right) G\left( \frac{q_2 - y}{h_0} \right) F_Y(y|X) \frac{\bar{y}}{y} = F_Y(q_1|X) + O(h_0^2).
$$
(ii) Define $Z_n(\tau) = \sum_{i=1}^n (f_{ni}(\tau) - \mathbb{E}f_{ni}(\tau))$. The covariance kernel of the limiting Gaussian process is $\lim_{n \to \infty} \mathbb{E}[Z_n(\tau_1)Z_n(\tau_2)] = \lim_{n \to \infty} n\mathbb{E}[f_n(\omega, \tau_1)f_n(\omega, \tau_2)] - n\mathbb{E}[f_n(\omega, \tau_1) \times \mathbb{E}[f_n(\omega, \tau_2)] = f(\tau_1(1-\tau_2) \int K^2(v) dv.$

(iii) $\sum_{i=1}^n \mathbb{E}[F_{ni}^2] = f(\tau) \int K(v)^2 dv.$

(iv) For any $\varepsilon > 0$, $\sum_{i=1}^n \mathbb{E}[F_{ni}^2 \{F_{ni} > \varepsilon\}] \to 0$. This is because $\mathbb{1}\{F_{ni} > \varepsilon\} = 0$ for $n$ large enough, by assuming $K$ is bounded and $\sqrt{n}h\to \infty$.

(v) $n\mathbb{E}[|f_{ni}(\tau_1) - f_{ni}(\tau_2)|^2] \to \rho(\tau_1, \tau_2)^2 \equiv f(\tau_1(1+\tau_1 - \tau_2) \int K(v)^2 dv$, uniformly in $\tau_1, \tau_2$. Therefore, uniformly in $\tau_1, \tau_2$, $\rho_n(\tau_1, \tau_2) \equiv \left(\sum_{i=1}^n \mathbb{E}[|f_{ni}(\tau_1) - f_{ni}(\tau_2)|^2]\right)^{1/2} \to \rho(\tau_1, \tau_2)$.

B. Proofs of Theorems 3–6 in Section 4.2

We use the $U$-process theorems in Sherman (1994) to prove Lemma 2, Lemma 3, and Theorem 3. Then, the proofs of Theorems 4 and 5 build on these results. We start with an overview of the proof of the $U$-process theorems.

Denote $\lambda \equiv (\tau, h, h_0, \delta) \in \Lambda \equiv \mathcal{T} \times \mathcal{R}_+ \times \mathcal{R}_+ \times \mathcal{R}_+$. Let $(Z_i, Z_j) \in \mathcal{Z}^2 \equiv \mathcal{Z} \times \mathcal{Z}$ from the product measure $\mathbb{P}^2 \equiv \mathbb{P} \otimes \mathbb{P}$. Let $\mathcal{F} \equiv \{(Z_i, Z_j) \mapsto p(Z_i, Z_j; \lambda) : \lambda \in \Lambda\}$ be a class of measurable functions on $\mathcal{Z}^2$. The collection $\{U_n p : p \in \mathcal{F}\}$ is a $U$-process of order 2 indexed by $\mathcal{F}$, where, for each $p \in \mathcal{F}$,

$$U_n p = \frac{1}{n(n-1)} \sum_{i=1}^n \sum_{j \neq i}^n p(Z_i, Z_j; \lambda)$$

$$= \frac{1}{n} \sum_{i=1}^n \mathbb{E}[p(Z_i, Z_i; \lambda)|Z_i] + \frac{1}{n} \sum_{j=1}^n \mathbb{E}[p(Z, Z_j; \lambda)|Z_j] - \mathbb{P}^2[p(Z_i, Z_j; \lambda)] + U_n^2,$$

$$U_n^2 = \frac{1}{n(n-1)} \sum_{i=1}^n \sum_{j \neq i}^n r(Z_i, Z_j; \lambda),$$

and $r(Z_i, Z_j; \lambda) \equiv p(Z_i, Z_j; \lambda) - \mathbb{E}[p(Z_i, Z; \lambda)|Z_i] - \mathbb{E}[p(Z, Z_j; \lambda)|Z_j] + \mathbb{P}^2[p(Z_i, Z_j; \lambda)]$. The proof involves the following steps.

**Step 1.** We show $\sup_{\mathcal{F}} |U_n^2| = o_P(n^{-1/2})$ by Corollary 4 in Sherman (1994).

**Step 2 [Projection].** Calculate the projection $r_{ni}(\tau) \equiv \mathbb{E}[p(Z_i, Z; \lambda)|Z_i] + \mathbb{E}[p(Z, Z_j; \lambda)|Z_i]$. Find the influence function $r_i(\tau)$ such that $n^{-1/2} \sum_{i=1}^n r_{ni}(\tau) = n^{-1/2} \sum_{i=1}^n r_i(\tau) + o_P(1)$, uniformly in $\tau \in \mathcal{T}$.

**Step 3 [Bias].** Calculate $\mathbb{E}[U_n p] = \mathbb{P}^2 p$, uniformly in $\tau \in \mathcal{T}$. For the weak convergence result, let the asymptotic bias converge to zero at a rate faster than root-$n$.

**Step 4 [Weak convergence].** By van der Vaart (2000), (i) monotonic and smooth function classes are Donsker and (ii) the Cartesian product of two Donsker classes of functions is also a Donsker class. By Donsker’s theorem, we complete the proof.

**Proof of Theorem 3.** By Theorem 1,

$$-\frac{1}{n} \sum_{i=1}^n (\hat{Q}_i Q_i - Q_i) \phi_i = U_n p + \frac{1}{n} \sum_{i=1}^n \phi_i R_n(\tau, X_i).$$

(20)
where the second-order U-statistic
\[ U_{np} = \frac{1}{n(n-1)} \sum_{i=1}^{n} \sum_{j \neq i} \phi(X_i, X_j) K(H^{-1}(X_i - X_j)) f(X_i) f(Y|X_i)|X_i| |H| (\tau - G(\frac{Q(\tau|X_i) - Y_j}{h_0})) 1_i \]
and the second term in (20) is \( O_p(n^{-1/2} \sum_{i=1}^{n} \|\phi_i(\cdot, \cdot, \cdot)|R_n(\tau, X_i)\|) = O_p(\sqrt{n} \sup_{X \in S, \tau \in \mathcal{T}} \|\phi(X)\| |R_n(\tau, X)|) \) by the condition (ii).

**Step 1.** We claim \( F_1 \equiv \{ (Z_i, Z_j) \mapsto h^d p(Z_i, Z_j; \lambda) : \lambda \in \Lambda \} \) is euclidean for the envelope \( F_1(Z_i, Z_j) = C \phi(X_i)/(\inf_{\tau \in \mathcal{T}} f_{XY}(X_i, Q(\tau|X_i))) \) that satisfies \( \mathbb{P}^2 F^2 = CE[\|\phi(X)\|^2]/(\inf_{\tau \in \mathcal{T}} f_{XY}(X_i, Q(\tau|X_i)))^2 < \infty \). The classes \( \{ X \mapsto Q(\tau|X) : \tau \in \mathcal{T} \}, \{ X \mapsto K((X - x)/h) : h > 0 \}, \{ (X, Y) \mapsto G((Q(\tau|X) - Y)/h_0) : \tau \in \mathcal{T}, h_0 > 0 \} \) and \( \{ \inf_{\tau \in \mathcal{T}} f_{XY}(X_i, Q(\tau|X)) \geq \delta : \delta > 0 \} \) are euclidean by Lemma 2.13 and Example 2.10 in Pakes and Pollard (1989) and p. 221 in Kosorok (2008). Then, Lemma 2.14 in Pakes and Pollard (1989) implies \( F_1 \) is euclidean.

Thus, we can apply Corollary 4 in Sherman (1994). Lemma 6 in Sherman (1994) implies the class of \( \mathbb{P} \)-degenerate functions of order 2 \( \{ (Z_i, Z_j) \mapsto h^d r(Z_i, Z_j; \lambda) : \lambda \in \Lambda \} \) is euclidean.

**Step 2 [Projection].** We show that uniformly in \( \tau \in \mathcal{T} \),
\[
\frac{1}{\sqrt{n}} \sum_{i=1}^{n} r_{ni} = \frac{1}{\sqrt{n}} \sum_{i=1}^{n} (r_{1ni} + r_{2ni}) \overset{(i)}{=} \frac{1}{\sqrt{n}} \sum_{i=1}^{n} r_{2ni} + o_p(1) \overset{(ii)}{=} \frac{1}{\sqrt{n}} \sum_{i=1}^{n} r_{3ni} + o_p(1) \overset{(iii)}{=} \frac{1}{\sqrt{n}} \sum_{i=1}^{n} r_{3i} + o_p(1),
\]
where \( r_{1ni} = \mathbb{E}[p(Z_i, Z; \lambda)|Z_i], r_{2ni} = \mathbb{E}[p(Z, Z_i; \tau)|Z_i], r_{3ni} = \frac{\phi(X_i)}{f_Y(Q(\tau|X_i)|X_i)} (\tau - G(\frac{Q(\tau|X_i) - Y_i}{h_0})) \), \( r_{3i} = A(X_i)(\tau - 1_{Y_i \leq Q(\tau|X_i)}), \) and \( A(X_i) = \frac{\phi(X_i)}{f_Y(Q(\tau|X_i)|X_i)} \). We prove equalities (i), (ii), and (iii) in the above equation in the following.

(i) We claim \( \sup_{\tau \in \mathcal{T}} \frac{1}{\sqrt{n}} \sum_{i=1}^{n} r_{ni} = o_p(1) \). We calculate \( r_{1ni} = \mathbb{E}[p(Z_i, Z; \lambda)|Z_i] \) in Lemma 5. Furthermore, by the condition \( \mathbb{E}[\|\phi(X)\|^2]/(\inf_{\tau \in \mathcal{T}} f_{XY}(X_i, Q(\tau|X_i)))^2 < \infty \), one can show \( \mathbb{E}[\|r_{1ni}\|^2] = O((h_0^2 + h^4)^2) = o(1) \). Chebyshev’s inequality implies the claim.

(ii) We claim \( \sup_{\tau \in \mathcal{T}} \frac{1}{\sqrt{n}} \sum_{i=1}^{n} (r_{2ni} - r_{3ni}) = o_p(1) \).
\[
r_{2ni} = \mathbb{E}[p(Z, Z_i; \tau)|Z_i] = \mathbb{E}\left[ \frac{\phi(X_i)}{f_Y(Q(\tau|X_i)|X_i)} \frac{1}{|H|} K_{\tau}(\tau - G(\frac{Q_j - Y_i}{h_0})) \right] Z_i = \int S f_Y(Q(\tau|X_i)|X_i) \frac{1}{|H|} K_{\tau}(\tau - G(\frac{Q_j - Y_i}{h_0})) dX_i = \int f_Y(Q(\tau|X_i + uh)|X_i + uh) (\tau - G(\frac{Q(\tau|X_i + uh) - Y_i}{h_0})) 1[X_i + uh \in S] du = r_{3ni} + o(h^4).
\]
By the argument for equality (i), it suffices that $E[\|r_{2ni} - r_{3ni}\|^2] = O(h^{2\nu})$.

(iii) We claim $T_n = n^{-1/2} \sum_{i=1}^{n} (r_{3ni} - r_{3i} - E[r_{3ni} - r_{3i}]) = o_p(1)$, uniformly in $\tau \in T$. 

$$E[\|r_{3ni} - r_{3i}\|^2] = E[\|A(X_i)\|^2 \left( G\left( \frac{Q(\tau|X_i) - Y_i}{h_0} \right) - 1\{Y_i \leq Q(\tau|X_i)\} \right)^2] = O(h_0)$$

by (19) and

$$\int_{\mathbb{Y}} G\left( \frac{Q_i - Y_i}{h_0} \right) f_{Y|X}(y|X_i) dy = G\left( \frac{Q_i - Y_i}{h_0} \right) F_{Y|X}(y|X_i) dy + \int_{\mathbb{Y}} \frac{1}{h_0} g\left( \frac{Q_i - Y_i}{h_0} \right) F_{Y|X}(y|X_i) dy = G(0) \tau + \tau/2 + f_Y(Q_i|X_i) O(h_0).$$

Furthermore, using (18), $E[r_{3ni} - r_{3i}] = O(h_0^2)$. Thus, $E[\|T_n\|^2] = o(1)$. The claim follows the argument for equality (i).

For the stochastic trimming function, by Proof of Lemma 4, $n^{-1} \sum_{i=1}^{n} \hat{Q}_i \phi_i 1(X_i \in S) - n^{-1} \sum_{i=1}^{\hat{S}} \hat{Q}_i \phi_i 1(X_i \in \hat{S}) = o_p(n^{-1/2}).$

**Step 3 [Bias].** The bias $E[U np] = O(h^\nu + h_0^2)$ by Lemma 5.

**Proof of Theorem 4.** Density-weighted AQD.

$$\hat{\beta}_f - \beta_f = -\frac{n}{2} \sum_{i=1}^{n} \hat{Q}(\tau|X_i) \nabla \hat{f}_i 1_i - \hat{\beta}_f$$

$$= -\frac{n}{2} \sum_{i=1}^{n} (\hat{Q}_i - Q_i) \nabla f_i 1_i - \frac{n}{2} \sum_{i=1}^{n} (Q_i \nabla \hat{f}_i 1_i - E[Q_i \nabla f_i]) - \frac{n}{2} \sum_{i=1}^{n} (\hat{Q}_i - Q_i) (\nabla \hat{f}_i - \nabla f_i) 1_i.$$

$$(I) \quad \Rightarrow (II) \quad \Rightarrow (III) \quad \Rightarrow s.o.$$

Decompose $(I) = n^{-1} \sum_{i=1}^{n} (-2\hat{Q}_i \nabla f_i 1_i - \beta_f) + (2\hat{Q}_i \nabla f_i 1_i + \beta_f)$, where the influence function for the first part is given in Theorem 3 with $\phi(X) = -2\nabla f(X)$. The influence function for $(III)$ is given in Lemma 2 with $\psi(X; \tau) = -2Q(\tau|X)$. For the third term $s.o.$,

$$\sup_{X_i \in S} \left\| -2(\hat{Q}_i - Q_i)(\nabla \hat{f}_i - \nabla f_i) \right\| = O_p\left( \frac{1}{\delta} \left( \frac{\log n}{n h^d} \right)^{1/2} \left( \frac{\log n}{n h_i^d + 2} \right)^{1/2} \right) = o_p(n^{-1/2})$$

by Lemma 1, Theorem 6 in Hansen (2008), and Assumption 3.

Combining the results and $\sqrt{n}(\hat{\beta}_f - \beta_f) = o_p(1)$ in Lemma 4, we obtain $r_f(Z_i; \tau)$. Combining the bias terms in Theorem 3 and Lemma 2, we obtain $\text{Bias}_f(\tau; h, h_0, h_1)$.

As argued in Step 4, we obtain the weak convergence, with the covariance $\text{Cov}(G(\tau_1), G(\tau_2)) = E[f_f(Z; \tau_1)] r_f(Z; \tau_2)'$.

**Scaled AQD.** By Theorem 4 with $\gamma(X_i; \tau) = 1$, $\hat{\alpha} - \alpha = n^{-1} \sum_{i=1}^{n} r_\alpha(X_i) + o_p(n^{-1/2})$, where the influence function $r_\alpha(X_i) = 2f(X_i - E[f(X)])$, as shown in Powell and Stoker.
(1996). Then, \( \sqrt{n} (\hat{\beta}_s - \beta_s) \)

\[
= \frac{\sqrt{n}}{\alpha \alpha} (\hat{\beta}_f \alpha - \beta_f \hat{\alpha}) = \frac{\sqrt{n}}{\alpha \alpha} ((\hat{\beta}_f - \beta_f) \alpha - \beta_f (\hat{\alpha} - \alpha))
\]

\[
= \frac{1}{\sqrt{n}} \sum_{i=1}^{n} (r_f(Z_i) - r_{\alpha}(X_i) \beta_s) / \hat{\alpha} + o_p(1).
\]

As argued in Step 4, we obtain the second part of Theorem 4.

**Proof of Theorem 5.**

\[
\hat{\beta}_W - \beta_W = -\frac{1}{n} \sum_{i=1}^{n} (Q_i - Q_i) \frac{\nabla(W_i \hat{f})}{f_i} 1_i - \frac{1}{n} \sum_{i=1}^{n} Q_i \frac{\nabla(W_i \hat{f})}{f_i} 1_i - \beta_W + s.o.1,
\]  \hspace{1cm} (21)

where \( s.o.1 = \frac{1}{n} \sum_{i=1}^{n} (Q_i - Q_i) \left( \frac{\nabla(W_i \hat{f})}{f_i} - \frac{\nabla(W_i \hat{f})}{f_i} \right) 1_i = \frac{1}{n} \sum_{i=1}^{n} (Q_i - Q_i) W_i \left( \frac{\nabla \hat{f} - \nabla f_i}{f_i} + \nabla f_i \left( \frac{1}{f_i} - \frac{1}{\hat{f}_i} \right) \right) 1_i. \) So by Assumption 4,

\[
\sqrt{n} \| s.o.1 \| = O_p \left( \sqrt{n} \| \hat{Q} - \hat{Q}_i \| \| \hat{f} - f_i \| + \| f_i \| + \| f_i \| \right)
\]

\[
= O_p \left( \frac{\log n}{\delta^2 \sqrt{nh_1^d h_2^d}} \left( h_1^{-1} + \delta^{-1} \right) \right) = o_p(1).
\]

The influence function of (I) is implied by Theorem 3 with \( \phi(X) = -\nabla(W(X)f(X))/f(X) \) by assuming \( \delta^5 n^{-1} h_1^d h_2^d \to \infty, \delta^8 n^{-1} h_1^d h_2^d \to \infty, \) and uniformly bounded functions.

The second term in (21) is further decomposed

\[
-\frac{1}{n} \sum_{i=1}^{n} Q_i \frac{\nabla(W_i \hat{f})}{f_i} 1_i = -\frac{1}{n} \sum_{i=1}^{n} Q_i \nabla W_i 1_i - \frac{1}{n} \sum_{i=1}^{n} Q_i \frac{W_i \nabla f_i}{f_i} (\hat{f}_i - f_i) 1_i + s.o.2,
\]  \hspace{1cm} (II)

where \( s.o.2 = \frac{1}{n} \sum_{i=1}^{n} Q_i \frac{W_i \nabla W_i}{f_i} (\hat{f}_i - f_i) \left( \frac{\nabla(W_i \hat{f})}{f_i} - \frac{\nabla(W_i \hat{f})}{f_i} \right) 1_i. \) So \( \| s.o.2 \| = o_p(\| s.o.1 \|). \)

The influence function of (II) is given by Lemma 2 with \( \psi(X; \tau) = -Q(\tau | X) W(X) / f(X), \)

\[
\sqrt{n} \left( (II) + \mathbb{E} \left[ \frac{f}{f} W \frac{\nabla W}{f} \right] \right) = \frac{1}{\sqrt{n}} \sum_{i=1}^{n} (f_i \nabla \left( \frac{Q_i W_i}{f_i} \right) - \mathbb{E} \left[ f_i \nabla \left( \frac{Q_i W_i}{f_i} \right) \right]) + o_p(1).
\]

The influence function for (III) is given by Lemma 3 with \( \gamma(X; \tau) = Q(\tau | X) W(X) \frac{\nabla f(X)}{f(X)}, \)

\[
\sqrt{n} (III) = \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \left( Q_i W_i \nabla f_i - \mathbb{E} \left[ Q_i W_i \nabla f_i \right] \right) + o_p(1).
\]
Therefore,

$$-\frac{1}{n} \sum_{i=1}^{n} Q_i \frac{\nabla(W_{\hat{f}_i})}{\hat{f}_i} = \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \nabla Q_i W_i + o_p(1).$$

As argued in Step 4, Donsker’s theorem implies the weak convergence. Combining the bias terms in Theorem 3 and Lemmas 2 and 3, we obtain $\text{Bias}_w(\tau; h, h_0, h_1)$. ■

**Proof of Theorem 6.** We follow Härdle and Stoker (1989) using the projection structure of the $U$-statistic. For $r_{\hat{f}_i}$ in Appendix C, let $\xi_{nij} = p(X_i, X_j; \lambda) + p(X_j, X_i; \lambda)$. The limit of $r_n(X_i; \lambda) = \mathbb{E}[\xi_{nij}|Z_i]$, denoted by $r_i \equiv r(X_i; \tau)$, is estimated by the sample analog, $\hat{r}_i \equiv (n-1)^{-1} \sum_{j \neq i} \hat{\xi}_{nij}$, where $\hat{\xi}_{nij}$ is obtained by a first-step nonparametric estimation of the unknown functions.

By similar arguments, we obtain $\sup_i |\hat{r}_i - r_i|1_i = o_p(1)$.

$$\sup_i |\hat{r}_i - r_i|1_i \leq \sup_i \left| \frac{1}{n-1} \sum_{j \neq i} (\hat{\xi}_{nij} - \xi_{nij}) \right| 1_i + \frac{1}{n-1} \sum_{j \neq i} \xi_{nij} - \mathbb{E}[\xi_{nij}|Z_i] 1_i$$

$$+ \sup_i |r_n(X_i; \lambda) - r(X_i; \tau)| 1_i = o_p(1)$$

by the uniform convergence of the nonparametric estimation, the law of large numbers, and the proof of Lemma 2.

By similar arguments, we obtain $\sup_i |\hat{r}_{\beta_i} - r_{\beta_i}|1_i = o_p(1)$. Let $r_{\beta} \equiv r_f(Z_i; \tau)$. Since the variance of $r_{\beta}$ exists and $Pr(f(X) \leq \delta) = o(1),

$$n^{-1} \sum_{i=1}^{n} \hat{r}_{\beta_i} - r_{\beta_i} 1_i = \mathbb{E}[r_{\beta} r_{\beta}']$$

$$= n^{-1} \sum_{i=1}^{n} (\hat{r}_{\beta_i} - r_{\beta_i}) (\hat{r}_{\beta_i} - r_{\beta_i})' 1_i + n^{-1} \sum_{i=1}^{n} r_{\beta_i} (\hat{r}_{\beta_i} - r_{\beta_i})' 1_i + n^{-1} \sum_{i=1}^{n} (\hat{r}_{\beta_i} - r_{\beta_i}) r_{\beta_i}' 1_i - n^{-1} \sum_{i=1}^{n} \hat{r}_{\beta_i} r_{\beta_i}' (1 - 1_i) + n^{-1} \sum_{i=1}^{n} r_{\beta_i} r_{\beta_i}' - \mathbb{E}[r_{\beta} r_{\beta}'] = o_p(1).$$

The same arguments prove $\text{Cov}(G_w(\tau_1), G_w(\tau_2))$ is consistent. ■

**Proof of Corollary 1.** The results are implied by Propositions 4.1 and 4.2 in Powell and Stoker (1996), so we verify their conditions, note the additional complication due to estimating the CQF and density derivative, and do not repeat the proofs.

(i) $B_{h^v}$ includes the leading terms associated with $h$ in $\text{Bias}_f$ in Theorem 4. The derivation of $\text{Bias}_f$ implies Assumption 1 in Powell and Stoker (1996).

Consider the variance. Following the proof of Theorem 4, (20) in Theorem 3 and (24) in Lemma 2 imply

$$p(Z_i, Z_j; \lambda) \equiv -2 \alpha' \nabla f(X_i) K(H^{-1}(X_i - X_j)) (\tau - G \left( \frac{Q(\tau|X_i) - Y_j}{h_0} \right) ) 1_i - 2 Q(\tau|X_i) 1_i \alpha' \nabla K \left( \frac{X_i - X_j}{h} \right) \frac{1}{h^{d+1}}. \quad (22)$$
So \( a^\prime \hat{\beta}_{f,h} = (n(n-1))^{-1} \sum_{i=1}^{n} \sum_{j \neq i} P(Z_i, Z_j; \lambda) + s.o. \) for some smaller-order term \( s.o. = o_p(n^{-1/2}) \) due to \( \hat{Q}(\tau | X_i) \) and \( \nabla \hat{f}(X_i) \). The standard formulation of \( U \)-statistic implies that the terms associated with \( h \) in the variance of \( \hat{\beta}_{f,h} \) are dominated by \( 2n^{-2}E[\hat{p}(Z_i, Z_j; \lambda)^2] \) for a symmetric \( \hat{p}(Z_i, Z_j; \lambda) = (p(Z_i, Z_j; \lambda) + p(Z_j, Z_i; \lambda))/2 \).\( \hat{p}(Z_i, Z_j; \lambda) \) is a plug-in estimator of \( p(Z_i, Z_j; \lambda) \). By (18) and (19), some algebra yields \( E[\hat{p}(Z_i, Z_j; \lambda)^2] = \nabla h^{-d} + o(h^{-d}). \) Thus, Assumption 2 in Powell and Stoker (1996) holds. Their Proposition 4.1 implies the result.

(ii) Consider the consistency of \( \hat{\Psi} \). The proof of Theorem 4, Theorem 1, and \( nh_\gamma^3 \to \infty \) implies \( s.o. = o_p(n^{-1/2}) \). It is straightforward to show that \( E[p(Z_i, Z_j; \lambda)^4] = O_p(h_{\gamma}^{-3d}) \) (i.e., \( \eta = d \) and \( \gamma = d \) in the notations and equation (4.39) of Powell and Stoker (1996)). Then, Proposition 4.2 of Powell and Stoker (1996) implies the result.

C. Proof of Lemmas

Proof of Lemma 1. This proof modifies the proofs of Theorems 2 and 6 in Hansen (2008) and Lemma B(1) in Cattaneo et al. (2013) that amends a truncation argument in the proof of Theorem 2 in Hansen (2008).

1. \( \hat{F}_Y(y|x) \equiv \hat{\Psi}(y, x)f(x) = \frac{\hat{\Psi}(y, x)f(x)}{f(x)} \), where \( \hat{\Psi}(y, x) \equiv (nh^d)^{-1} \sum_{i=1}^{n} K(H^{-1}(X_i - x))G\left(\frac{y - Y_i}{h_0}\right) \), for \( x \in C_n \) and \( y \in \mathcal{Y}. \) Consider the uniformity over \( \mathcal{Y} \times C_n \). Construct a grid using regions of the form \( B_j = \{ y : |y - y_j| \leq a_n h \} \times \{ x : |x - x_j| \leq a_n h \}. \) Since we have a bounded dependent variable \( G\left(\frac{y - Y_i}{h_0}\right) \in (0, 1) \), the argument for uniform bound is the same, for example, in (A.8) of Hansen (2008) \( K(x_2)G\left(\frac{x_2 - x_1}{h_0}\right) - K(x_1)G\left(\frac{x_1 - x_2}{h_0}\right) \leq \xi K^*(x_1), \) for all \( \| (y_1, x_1) - (y_2, x_2) \| \leq \xi \leq L. \) Therefore, Hansen’s proof of Theorem 2 gives \( \sup_{x \in C_n, y \in \mathcal{Y}_n} |\hat{\Psi}(y, x) - E[\hat{\Psi}(y, x)]| = O_p\left(\frac{\log n}{nh^d}\right)^{1/2}. \) By change of variables, the smoothness assumptions, and the dominated convergence theorem, for any \( y \in \mathcal{Y}_n \) and \( x \in C_n \),

\[
E[\hat{\Psi}(y, x)] = \frac{1}{nh^d} \mathbb{E} \left[ K(H^{-1}(X - x))G\left(\frac{y - Y_i}{h_0}\right) \right] = \frac{1}{nh^d} \mathbb{E} \left[ F_Y(y|X) + \frac{h_0^2}{2} \right] = F_Y(y|x)f(x) + O(h^\gamma + h_0^2).
\]

Thus, \( \sup_{x \in C_n, y \in \mathcal{Y}} |\hat{\Psi}(y, x) - \Psi(y, x)| = O_p(a^\gamma), \) where \( a^\gamma \equiv \left(\frac{\log n}{nh^d}\right)^{1/2} + h_0^2 + h^\gamma \) and \( \Psi(y, x) = F_Y(y|x)f(x). \) Theorem 6 in Hansen (2008) gives

\[
\sup_{x \in C_n} |\hat{f}(x) - f(x)| = O_p(a^\gamma), \text{ where } a^\gamma = \left(\frac{\log n}{nh^d}\right)^{1/2} + h^\gamma.
\]

Therefore, uniformly in \( y \in \mathcal{Y} \) and \( x \in C_n \),

\[
\hat{F}_Y(y|x) = \frac{\hat{\Psi}(y, x)f(x)}{f(x)} = \frac{F_Y(y|x) + O_p(a^\gamma \delta^{-1})}{1 + O_p(a^\gamma \delta^{-1})} = F_Y(y|x) + O_p(a^\gamma \delta^{-1}).
\]

2. Similarly, \( \frac{\partial}{\partial x} \hat{F}_y(y|x) \equiv \hat{f}_y(y|x) \equiv \hat{\Psi}(y,x) / \hat{f}(x) \), where \( \hat{\Psi}(y,x) \equiv (nh^d h_0)^{-1} \sum_{i=1}^n g(Y_i - y) K(H^{-1}(X_i - x)) \). Theorem 6 in Hansen (2008) implies \( \text{sup}_{x \in C_n, y \in Y} |\hat{\Psi}(y,x) - \mathbb{E}[\hat{\Psi}(y,x)]| = O_p\left( \left(\frac{\log n}{nh^d h_0}\right)^{1/2} \right) \). A similar calculation yields \( \text{Bias}_p(\hat{\Psi}(y,x)) = O(h^\nu + h_0^2) \).

Proof of Lemma 2. We suppress the subscript in \( h_1 \) and \( v_1 \) for notational simplicity. Denote \( \lambda \equiv (\tau, h) \in \mathcal{T} \times \mathcal{R}_+ \).

\[ U_n \equiv \frac{1}{n} \sum_{i=1}^n \psi_i(X_i; \tau) \nabla \hat{f}_i \mathbf{1}_i = \frac{1}{n(n-1)} \sum_{i=1}^n \sum_{j=1, j \neq i}^n p(X_i, X_j; \lambda), \]

where

\[ p(X_i, X_j; \lambda) \equiv \psi_i(X_i; \tau) \mathbf{1}_i \nabla K \left( \frac{X_i - X_j}{h} \right) \frac{1}{h^{d+1}}. \]  

(24)

The proof follows the procedure outlined at the beginning of Appendix B.

Step 1. Using the same arguments in Proof of Theorem 3, we show \( \mathcal{F}_1 \equiv \{(Z_i, Z_j) : \lambda \in \Lambda \} \) is euclidean for the envelope \( F_1(Z_i, Z_j) = \sup_{x \tau \in \mathcal{T}} \psi(X_i; \tau) \) satisfying \( \mathbb{P}^2 F_1^2 < \infty \). Assume \( nh^{2d+2} \to \infty \) and apply Corollary 4 in Sherman (1994). Then, Lemma 6 in Sherman (1994) implies the class of \( \mathbb{P} \)-degenerate functions of order 2 \( \{(Z_i, Z_j) \mapsto h^{d+1} r(Z_i, Z_j; \lambda) : \lambda \in \Lambda \} \) is euclidean.

Step 2.

\[ r_n(X_i; \lambda) \equiv \mathbb{E}[p(X_i, X_j; \lambda)|X_i] + \mathbb{E}[p(X_j, X_i; \lambda)|X_j] \]

\[ \int_{\mathcal{X}} \frac{1}{h^{d+1}} \nabla K_{ij} f(X_j) dX_j \psi_i \mathbf{1}_i + \int_{\mathcal{X}} \frac{1}{h^{d+1}} \nabla K_{ji} f(X_j) dX_j \psi_j \mathbf{1}_j \]

\[ = \psi_i \mathbf{1}_i \left( \frac{1}{h^{d}} K_{ij} f(X_j) \mathbf{1}_j + \frac{1}{h^{d}} \int_{\mathcal{X}} K_{ij} \nabla f(X_j) dX_j \right) \]

\[ + \frac{1}{h^d} \left( K_{ij} f(X_j) \psi_j \mathbf{1}_j \right) \nabla \phi \left( f(X_j) \psi_j \mathbf{1}_j \right) \]

\[ = \psi_i \mathbf{1}_i \int K(V) \nabla f(X_i + HV) dV - \int K(V) \nabla (f(\psi)(X_i + HV)) \mathbf{1}_{X_i + HV \in S} dV \]

\[ = r(X_i; \tau) + O_p(h^\nu). \]

Let \( r(X_i; \tau) \equiv \psi_i(X_i; \tau) \nabla f_i - \nabla (\psi_i(X_i; \tau) f_i) = -f_i \nabla \psi_i(X_i; \tau) \). The conditions imply \( \mathbb{E}[r_n(X; \lambda) - r(X_i; \tau)]^2 = \mathbb{E}[\psi(X; \tau)^2] O(h_1^{2v_1}) = o(1), \) so \( n^{-1/2} \sum_{i=1}^n (r_n(X_i; \lambda) - r(X_i; \tau)) \to o_p(1). \)

Let \( r(X_i; \tau) = 2y(X_i; \tau) f(X_i) \). By similar arguments in Proof of Theorem 3, \( \mathbb{E}[r_n(X; \lambda) - r(X_i; \tau)]^2 = O \left( h_1^{2v_1} \right) = o(1), \) so \( n^{-1/2} \sum_{i=1}^n (r_n(X_i; \lambda) - r(X_i; \tau)) \to o_p(1). \)

Step 3 [Bias]. Assuming \( p_x > v + 2, \)

\[ \mathbb{E}^2 p(X_i, X_j; \lambda) = \mathbb{E} \left[ \psi(X; \tau) \mathbf{1}_{X \in S} \int K(u) \nabla f(X + uh) du \right] \]

\[ = \mathbb{E} \left[ \psi(X; \tau) \nabla f(X) \right] + \frac{h^\nu k_v}{v!} \sum_{k=1}^d \mathbb{E} \left[ \psi(X; \tau) \partial_k^v \nabla f(X) \right] + O_p(h^{v + 1}). \]
Thus, \( n^{-1} \sum_{i=1}^{n} \psi(X_i; \tau) \nabla \hat{j}_i 1_i = n^{-1} \sum_{i=1}^{n} -f_i \nabla \psi_i - E[\psi \nabla f] \). By integration by parts, 
\(-E[\psi \nabla f] = E[\nabla \psi f] = E[V \psi f] + E[\psi \nabla f]\). Thus, \(-2E[\psi \nabla f] = E[\nabla \psi f]\).

**Proof of Lemma 3.** By the same steps as in the proof of Lemma 2, define \( p(X_i, X_j; \lambda) \equiv K_h(X_i - X_j) \gamma(X_i; \tau) 1_i \). We only note the difference without repeating each step.

**Step 2.**

\[
r_n(X_i; \lambda) = \mathbb{E}[p(X_i, X_j; \lambda) 1_i] + \mathbb{E}[p(X, X_i; \lambda) 1_i]
\]

\[
= \int_{\mathcal{X}'} \left\{ \frac{1}{h^2} K_{ij}(X_i) dX_j \gamma_i 1_i + \int_{\mathcal{X}'} \left\{ \frac{1}{h^2} K_{ij} \gamma f_j 1_j dX_j \right\} \right\} dx
\]

\[
= \gamma_i 1_i \left\{ \int K(V)f_i + HV dx + \int K(V)(\gamma f)(X_i + HV) 1_i \right\} \mathbb{E}[S \in S] \mathbb{E}[V].
\]

Let \( r(X_i; \tau) = 2\gamma(X_i; \tau) f(X_i) \). The conditions imply \( E\|r_n(X; \lambda) - r(X; \tau)\|^2 = O(h^{2n}) = o(1) \), so \( n^{-1/2} \sum_{i=1}^{n} r_n(X_i; \lambda) - r(X_i; \tau) = o_p(1) \). Then, \( n^{-1} \sum_{i=1}^{n} \psi(X_i; \tau) \hat{f}(X_i) 1_i - \mathbb{E}[\gamma(X; \tau) f(X)] = n^{-1} \sum_{i=1}^{n} 2\gamma(X_i; \tau) f(X_i) - 2\mathbb{E}[\gamma(X; \tau) f(X)] + o_p(n^{-1/2}).

**Step 3 [Bias].** Assuming \( p_\tau \geq v + 1 \),

\[
\mathbb{E}[r_n(X_i; \lambda)] = \mathbb{E}\left[\gamma(X; \tau) \int K(u)f(X + uh)du\right]
\]

\[
= \mathbb{E}\left[\gamma(X; \tau) f(X)\right] + \frac{h^v k_v}{v!} \mathbb{E}\left[\gamma(X; \tau) \sum_{k=1}^{d} \partial_k^v f(X)\right] + o_p(h^{v+1}).
\]

**Proof of Lemma 4.** Following Lavergne and Vuong (1996), choose \( \epsilon_n \) such that \( \epsilon_n^{-1} \sup_{X \in S, \tau \in T} |\hat{j}_{XY}(X, \hat{Q}(\tau X)) - f_{XY}(X, Q(\tau X))| = o_p(1) \) and \( \epsilon_n / \delta = o(1) \), which exists because

\[
\sup_{X \in S, \tau \in T} |\hat{j}_{XY}(X, \hat{Q}(\tau X)) - f_{XY}(X, Q(\tau X))|
\]

\[
\leq \sup_{X \in S, \tau \in T} |\hat{j}_{XY}(X, \hat{Q}(\tau X)) - f_{XY}(X, Q(\tau X))|
\]

\[
+ \sup_{X \in S, \tau \in T} |f_{XY}(X, \hat{Q}(\tau X)) - f_{XY}(X, Q(\tau X))|
\]

\[
= O_p((\log n / (nh^d))^{1/2} (h_0^{-1/2} + \delta^{-1})).
\]

Since \( \epsilon_n / \delta = o(1) \), we can work with the bound \( \delta + \epsilon_n \) instead of \( \delta \). Define \( S_c \equiv \{ x : \inf_{\tau \in T} f_{XY}(x, Q(\tau X)) \geq \delta + \epsilon_n \} \) and \( S_{c-} \equiv \{ x : \inf_{\tau \in T} f_{XY}(x, Q(\tau X)) \geq \delta - \epsilon_n \} \).

\[
\sqrt{n} (\beta - \hat{\beta}) = \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \hat{Q}_t \hat{f}_i \left( 1_{X_i \in S_c} - 1_{X_i \in \hat{S}} \right)
\]

\[
= \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \hat{Q}_t \hat{f}_i \left( 1_{X_i \in S_c, X_i \notin \hat{S}} - 1_{X_i \notin S_c, X_i \in \hat{S}} \right).
\]

For any \( x \in \mathcal{X} \) and \( \tau \in T \), the event \( \{ x \in S_c, x \notin \hat{S} \} \subseteq \{ \hat{j}_{XY}(x, \hat{Q}) - f_{XY}(x, Q) \geq \epsilon_n, x \in S_c \} \leq \{ \sup_{x \in \mathcal{X}, \tau \in T} |\hat{j}_{XY}(x, \hat{Q}) - f_{XY}(x, Q)| 1_{x \in \mathcal{S}} > \epsilon_n \} \) has asymptotic probability zero.
Hence, \(1\{X_i \in S_c, X_i \notin \hat{S}\} = 0\) \(\forall p.a.1\), for all \(i\). So we need to consider the second term only. Define \(I_{ni} \equiv 1\{X_i \notin S_c, X_i \in \hat{S}\} \).

\[
\sup_{\tau \in T} \left\| \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \hat{Q}_i \hat{\phi}_i I_{ni} \right\| \\
\leq \sup_{\tau \in T} \left\| n^{-1/2} \sum_{i=1}^{n} (\hat{Q}_i - Q_i) \phi_i I_{ni} \right\| + \sup_{\tau \in T} \left\| n^{-1/2} \sum_{i=1}^{n} Q_i (\hat{\phi}_i - \phi_i) I_{ni} \right\| \\
+ \sup_{\tau \in T} \left\| n^{-1/2} \sum_{i=1}^{n} (\hat{Q}_i - Q_i) (\hat{\phi}_i - \phi_i) I_{ni} \right\| + \sup_{\tau \in T} \left\| n^{-1/2} \sum_{i=1}^{n} Q_i \phi_i I_{ni} \right\|. 
\]

(25)

For the last term in (25),

\[
\mathbb{E} \left[ \left\| n^{-1/2} \sum_{i=1}^{n} Q_i \phi_i I_{ni} \right\|^2 \right] \\
\leq n^{-1} \mathbb{E} \left[ \left( \sum_{i=1}^{n} \|Q_i \phi_i\| 1\{X_i \notin S_c\} \right)^2 \right] \\
= \mathbb{E} \left[ \|Q_i \phi_i\|^2 1\{X_i \notin S_c\} \right] + (n-1) \left( \mathbb{E} \left[ \|Q_i \phi_i\| 1\{X_i \notin S_c\} \right] \right)^2 = o(1),
\]

where the first term is \(o(1)\) by Lebesgue dominated convergence theorem with \(\mathbb{E} \|Q_i \phi_i\|^2 \leq \infty\) and \(\delta + \epsilon_n \to 0\). For the second term, \(\int_{B_{\epsilon_n}} \|Q_i \phi_i\| f_{XY} dX_i = o(n^{-1/2})\) in Assumption 3 or 4, where \(B_{\epsilon_n} \equiv \{X : \sup_{\tau \in T} f_{XY}(X, Q(\tau |X)) < \delta + \epsilon_n\}\).

Now, consider the first term of (25). The event \(\{x \notin S_c, x \in \hat{S}, |\hat{f}_{XY}(x, \hat{Q}) - f_{XY}(x, Q)| > \epsilon_n\} \subseteq \{|\hat{f}_{XY}(x, \hat{Q}) - f_{XY}(x, Q)| > \epsilon_n\}\) has asymptotic probability zero. Observe that \(\{x \notin S_c, x \in \hat{S}, |\hat{f}_{XY}(x, \hat{Q}) - f_{XY}(x, Q)| \leq \epsilon_n\} \subseteq \{x \in S_{c-}\}\).

\[
\sup_{\tau \in T} \left\| n^{-1/2} \sum_{i=1}^{n} \phi_i (\hat{Q}_i - Q_i) \right\| I_{ni} \\
\leq \sup_{\tau \in T} n^{-1/2} \sum_{i=1}^{n} \|\phi_i (\hat{Q}_i - Q_i)\| I_{ni} \\
\leq \sup_{\tau \in T, x \in S} \left\{ |\hat{Q}(\tau |x) - Q(\tau |x)| 1\{x \in S_{c-}\} \right\} n^{-1/2} \sum_{i=1}^{n} \|\phi_i\| I_{ni} \\
= O_p(\delta^{-1} (nh^d)^{-1/2}) O_p(1) = o_p(1),
\]

where \(n^{-1/2} \sum_{i=1}^{n} \|\phi_i\| I_{ni} = O_p(1)\) by the central limiting theorem by \(\mathbb{E} \|\phi_i\|^2 < \infty\), and the uniform convergence of \(\hat{Q}_i\) is implied by Theorem 1 and Assumption 3 or 4. By the similar arguments, the remaining terms of (25) vanish in probability.
Proof of Lemma 5. Define the operator $\Gamma_v$ on a function $f : \mathcal{V} \to \mathcal{R}$, where $\mathcal{V}$ is an open and convex subset of $\mathcal{R}^d$ by

$$
\Gamma_v f(X + HV) \equiv \Gamma_v f(\bar{X}) = h \sum_{k=1}^d \partial_k f(X)V_k + \frac{h^2}{2} \sum_{k_1=1}^d \sum_{k_2=1}^d \left[ \partial_{k_1} \partial_{k_2} f(X) \right] V_{k_1} V_{k_2} + \ldots
$$

$$
+ \frac{h^v}{(v-1)!} \sum_{k_1=1}^d \cdots \sum_{k_{v-1}=1}^d \left[ \partial_{k_1} \cdots \partial_{k_{v-1}} f(X) \right] V_{k_1} \cdots V_{k_{v-1}}
$$

$$
+ \frac{h^v}{v!} \sum_{k_1=1}^d \cdots \sum_{k_v=1}^d \left[ \partial_{k_1} \cdots \partial_{k_v} f(\bar{X}) \right] V_{k_1} \cdots V_{k_v},
$$

where $V_k$ is the $k$th component of the vector $V$ and $\bar{X}$ is on the line segment of $X$ and $X + HV$. Hence, Taylor’s theorem expands $f(X + HV) = f(X) + \Gamma_v f(X + HV)$ for small $H$. By (18), for all $X_i$,

$$
\mathbb{E} \left[ \frac{1}{|H|} K_{ij} (G_{ij} - \tau) | x_i \right]
$$

$$
= \int_{\mathcal{V}} \frac{1}{|H|} K_{ij} \left( -\tau + F_Y(Q_i | X_i) + \frac{h^2}{2} f'_Y(Q_i | X_i) \kappa G2 + O(h^3_0) \right) f(X_i) dX_i
$$

$$
= \int_{\mathcal{V}} K(V) \left( -\tau + F_Y(Q_i | X_i + HV) + \frac{h^2}{2} f'_Y(Q_i | X_i + HV) \kappa G2 + O(h^3_0) \right) f(X_i + HV) dV
$$

$$
= \int_{\mathcal{V}} K(V) \left( -\tau + F_Y(Q_i | X_i) + \Gamma_v F_Y(Q_i | \bar{X}) + \frac{h^2}{2} \kappa G2 f'_Y(Q_i | X_i) \Gamma_v f(\bar{X}) \right) dV
$$

$$
+ \frac{h^2}{2} \kappa G2 F'_Y(Q_i | X_i) f(X_i) + \frac{h^2}{2} \kappa G2 f'_Y(Q_i | \bar{X}) \Gamma_v f(X_i) + O(h^3_0)
$$

$$
= \frac{h^2}{2} \kappa G2 f'_Y(Q_i | X_i) f(X_i) + \frac{h^v}{v!} \kappa v \sum_{k=1}^d \partial^v_k F_Y(Q_i | X_i) f_i + \int K(V) \Gamma_v F_Y(Q_i | \bar{X}) \Gamma_v f(\bar{X}) dV
$$

$$
+ \frac{h^2}{2} \kappa G2 f'_Y(Q_i | X_i) f(X_i) + \frac{h^v}{v!} \kappa v \sum_{k=1}^d \partial^v_k f'_Y(Q_i | X_i) f_i + \frac{h^2}{2} \kappa G2 f'_Y(Q_i | X_i) f(X_i) + O(h^{v+1} + h^3_0)
$$

$$
= \frac{h^2}{2} \kappa G2 f'_Y(Q_i | X_i) f(X_i) + \frac{h^v}{v!} \kappa v \sum_{k=1}^d \partial^v_k F_Y(Q_i | X_i) f_i
$$

$$
+ \sum_{l=1}^{v-1} \frac{h^v}{(v-l)!} \kappa v \sum_{k=1}^d \partial^v_k f_Y(Q_i | X_i) \partial^{v-l}_k f(X_i) + h^v h^2_0 R_I(X_i) + O(h^3_0 + h^{v+1}).
$$
where $\tilde{X}_i$ is on the line segment between $X_i$ and $X_i + HV$, by the dominated convergence theorem and the uniform continuity of $\partial_{k_1} \cdots \partial_{k_\nu} f(X)$ and $\partial_{k_1} \cdots \partial_{k_\nu} f'_Y (y|X)$ for $k_1, \ldots, k_\nu \in \{1, \ldots, d\}$ in $X$.

Since $1 \{X_i \notin S\} = o(1)$ by $\delta \to 0$ and the moments exist, by the dominated convergence theorem,

$$
E[U_{np}] = -E \left[ \frac{\phi_i}{f_i f_Y (Q_i|X_i)} \left\{ \frac{h_0^2}{2} G_2 f_Y (Q_i|X_i) f_i 
+ h^\nu \kappa_\nu \sum_{\ell=1}^\nu \frac{1}{\ell! (\nu - \ell)!} \sum_{k=1}^d \partial_{k}^\ell f_Y (Q_i|X_i) \partial_{k}^{\nu-\ell} f(X_i)
+ h^\nu h_0^2 R_f (X_i) \right\} \right] + o(h^\nu + h_0^2) = O(h^\nu + h_0^2).
$$
