Studies on Agrobacterium mediated in planta genetic transformation in black gram (*Vigna mungo* L.) cultivar VBN 3

Nukala Sumanth Kumar, Rohini Srivastava, Prakash M, Murugan S and Anandan R

**Abstract**

In planta genetic transformation protocols were standardized for the black gram (*Vigna mungo* L.) cv. VBN 3, an important grain legume. A binary vector p Bin AR harbouring *cry1AcF* gene isolated from E. coli competent cells was transformed into Agrobacterium strain EHA105 using freeze-thaw method and its presence was confirmed by colony PCR analysis of the selected single colonies for examining the presence of the *npt II* and *cry1AcF* genes. The integrity of plasmid was checked by restriction analysis. *Agrobacterium tumifaciens*-mediated transformation was performed using strain EHA105 harboring the binary vector p Bin AR carrying *cry1AcF* gene under the control of CaMV35s promoter where *cry1AcF* as insect resistance gene and *npt II* gene as a selectable markers. Antibiotic sensitivity test was conducted with sprouted half-seed and 1-week-old cotyledons with kanamycin at 50 mg/l completely inhibited the shoot formation and explants survival. Genetic transformation experiments were carried out using cotyledonary explants and it was found to be unsuccessful event while regenerating the transformed cotyledons due to its recalcitrance nature. Therefore, Agrobacterium mediated in planta transformation was performed using sprouted half-seed explants of VBN 3. The transformation event consisted of sonicating the explants for 3 minutes and vacuum infiltration (750 mm of Hg) for 2 minutes in Agrobacterium (pBinAR-cry1AcF) and co-cultivation for 3 days in MS medium with acetylsyringone (100µM). The transformed explants forming shoots were selected in MS medium supplemented with kanamycin 50 mg/l. The non-transformed shoots were completely bleached after selection. The presence and integration of *npt II* and *cry1AcF* transgenes into the black gram genome was confirmed by polymerase chain reaction (PCR). PCR analysis in 20 selected putative transformed black gram plantlets did not show amplification for *cry1AcF* and *npt II* genes. Work is in progress to grow the T0 seeds for molecular characterization of the inserted transgene among T1 plants.

**Keywords:** *Agrobacterium*, in-planta genetic transformation, *npt II*, pBinAR-cry1AcF

**Introduction**

Black gram (*Vigna mungo* L. Hepper) or urd bean is a widely grown grain legume belongs to family Fabaceae and genus Vigna. It is reported to have originated in South Asia and distributed in tropical and subtropical regions of India (Kapildev et al., 2016) [3]. It is a nitrogen fixing, short duration and tropical pulse grown as either sole or as intercrop or as fallow crop in many parts of India. Black gram seed consists of protein (25-28%), oil (1.0 - 1.5%), fibre (3.5-4.5%), ash (4.5-5.5%) and carbohydrates (62-65%) and are commonly used as ingredients in making dal for curries, soup, sweets and snacks. Globally pulses are grown on 81 million hectares of area with an annual production of 73.21 million tonnes (FAOSTAT, 2013-2014). Among the pulses, pigeon pea, black gram and green gram are the major contributors of the total pulses production. Black gram production in the country is largely concentrated in five states viz., Uttar Pradesh (U.P), Maharashtra, Madhya Pradesh, Andhra Pradesh and Tamil Nadu. These five states together contribute for about 70% of total production in the country. The average productivity of black gram in Tamil Nadu is about 412 kg/ha which is very low when compared to Indian average of 555 kg/ha. The major production constraints in black gram include several stress factors (biotic and abiotic), which led to significant yield loss are susceptibility to yellow mosaic virus (VMYMCV) (Sahoo et al., 2002) [8], fungal pathogens (powdery mildew, cercospora leaf spot), bruchids (Sahoo et al., 2002) [9], and pod borer (Rao and Chand, 2006) [7]. Gram pod borer (*Helicoverpa armigera*) is considered a serious lepidopteran pest of the crop, and has resulted in significant economic losses (40-60%) in the world and India has not been an exception. The production of black gram is still insufficient to meet the requirement of increasing human population. Hence, it is important to develop genetically
engineered black gram cultivars with cry genes for pod borer resistance.

Legumes are extremely recalcitrant to in vitro culture and genetic transformation. Limited reports are available in connection with Agrobacterium-mediated transformation in black gram using different explants, such as cotedyledary node and shoot apex (Saini and Jaiwal, 2005) [9]. Although the previous reports showed positive results in black gram transformation, many constraints still exist to limit the improvement of black gram with desirable traits. Agrobacterium-mediated in planta transformation is an effective method to produce huge number of transgenic lines in a shorter time. In planta transformation method has been adopted in several crops such as Glycine max, Arachis hypogaea, Arabidopsis thaliana, Raphanus sativus, Cicer arietinum, Beta vulgaris, Gossypium hirsutum, Solanum lycopersicum and Brassica jancea. Molecular markers can be used as diagnostic tool to identify the presence of a specific gene with accuracy and transfer it to different backgrounds. During pyramiding of genes it is difficult to select plants with multiple resistance genes based on phenotype alone as there may be epistatic effects. The main objective of this study is to transform black gram cv. VBN 3 via sonication and vacuum infiltration of sprouted seeds with Agrobacterium harboring a synthetic cry1AcF gene.

Materials and Methods
Genetically pure black gram seeds of VBN 3 were collected from The National Pulses Research Centre at Vambam in Pudukkottai district, Tamil Nadu, India was used for the present investigation.

Surface sterilization and explants preparation
Sterilization is the method which results in the removal of all microorganisms and other pathogens from an object or surface by treating it with chemicals or subjecting it to high heat or radiation. Mature black gram seeds were surface sterilized in 0.1% mercuric chloride (HgCl₂) for 30 sec and rinsed thoroughly with sterile double distilled water for three times. The sprouted seeds were de-coated aseptically and dissected into two halves. Single cotyledon with embryo axis was used as explant for in planta transformation study.

Media preparations
All experiments were conducted using MS basal medium. Unless otherwise stated, 30g/l of sucrose was used as a carbon source and phytogel was used as a gelling agent at a rate of 4.0 g/l in all media, plant growth regulators were added prior to autoclaving. The pH of the medium was adjusted to 5.8 by 1N NaOH or 1N HCl. The media were steam sterilized in a autoclave under 1.5 kg/cm and 121˚C for 20 mins and allowed to grow overnight in a rotary shaker at 37˚C for 125 rpm. 1ml of overnight grown culture was inoculated in 30ml of LB broth and subculture is done. The cell suspension is maintained at 0˚C for 20 minutes by keeping it on ice. Then, it is centrifuged at 5000 rpm for 10 minutes at 4˚C. The supernatant was discarded and the pellet was resuspended in sterile ice cold 100 mM CaCl₂ and kept on ice for immediate use.

Preparation of E. coli DH5α competent cells
A single colony of DH5α was inoculated in 3 ml of LB broth and allowed to grow overnight in a rotary shaker at 37˚C for 125 rpm. 1ml of overnight grown culture was inoculated in 30ml of LB broth and subculture is done. The cell suspension is maintained at 0˚C for 20 minutes by keeping it on ice. Then, it is centrifuged at 5000 rpm for 10 minutes at 4˚C. The supernatant was discarded and the pellet was resuspended in sterile ice cold 100 mM CaCl₂ and kept on ice for immediate use.

Mobilization of Plasmid into E. coli DH5α component cells
To an aliquot of 200µl competent cell suspension of DH5α, 1 µl (100 ng) of the plasmid pBinAR – cry1AcF was mixed and incubated on ice for 30 min by giving a heat shock at 42˚C for 90 seconds and again it was incubated on ice for 5-10 min. Then, to the suspension 1ml LB broth was added and incubated at 37˚C for 1 hour. After incubation, 50-100 µl of the cell suspension was placed on LB agar medium with kanamycin (50 mg/l) and incubated at 37˚C overnight.

Isolation of plasmid DNA E. coli by alkaline lysis method
2 ml of bacterial culture is added in a centrifuge tube and centrifuged at 12000 rpm for 1min at 4˚C. The supernatant was discarded and the suspending pellet was added with 100 µl ice cold solution I (25 mM Tris base, 10 mM EDTA and 50 mM glucose) and vortex it followed by which 200 µl of solution II (0.2 N NaOH and 1% SDS,) was added and 150 µl of solution III (5 M Potassium acetate, Glacial acetic acid and double distilled water) was added and kept on ice for 5mins and centrifuged at 12000 rpm for 5 mins at 4˚C. Now the supernatant is added to a new epppendorf tube along with 300 µl of cold isopropanol solution and allowing it for 10-20 mins at 25˚C. The above mentioned ingredients were centrifuged for 5mins at 4˚C. Decanting the isopropanol the pellet is dried and rinsed with 70% ethanol and again the pellet was dried removing the supernatant. And the pellet is dissolved in 50 µl of TE buffer and stored at -20˚C.

Restriction digestion of plasmid DNA
Restriction digestion of plasmid DNA isolated from transformed DH5α cells was done as per the standard procedures with the view to confirm the presence of pBinAR and to check the structural integrity of the construct. Approximately 200-250 ng of plasmid DNA was digested with restriction enzymes HindIII + EcoRI, BamHI + SalI, nptII in appropriate buffers at 37˚C for 1 hour. The DNA sample along with buffer and restriction enzymes were added to a clean tube and incubated at the digestion temperature (usually 37˚C) for 1 hour. The digestion was stopped by heat inactivation (65˚C for 15 minutes) or by addition of 10Mm final concentration EDTA. The digested products were analyzed in 0.8% agarose gel.

Agarose gel electrophoresis
Required amount of agarose was weighed (0.8% w/v) and melted in 1xTBE buffer. Ethidium bromide (1-2 µl) was added from the stock (10 mg/l H₂O). After cooling to 50-55˚C, the mixture was poured on to a preset template with an appropriate comb. DNA to be analysed was mixed with the gel loading buffer and loaded into the well. Electrophoresis was carried out at 60 V, to separate the restriction products.
Transformation of pBinAR construct to EHA105 cells
The binary vector pBinAR harbouring cry1AcF isolated from E. coli competent cells was transformed into Agrobacterium strain EHA105 using the freeze-thaw method. The Agrobacterium competent cells were prepared in a similar way as for E. coli and stored at -80°C. Thaw the competent Agrobacterium cells on ice if it is stored on -70°C or use the freshly prepared competent cells (use 250 µl per transformation reaction) and add DNA (1-5µl of CaCl2 purified DNA or 10 µl of standard E. coli miniprep DNA). Incubate the mixture on ice for 5minutes. Transfer the mixture to liquid nitrogen and incubate for 5minutes and again, do the same for another 5 minutes in a water bath at 37°C. Add 1ml of LB broth to each tube, seal it and place the tubes on a rocking table for 2-4 hours at room temperature. Collect the cells by spinning briefly in a micro centrifuge and spread them on two LB agar plates containing antibiotic (kanamycin 50 mg/l) for the T-DNA vector. Incubate the cells for 2 days at 28°C.

Colonv PCR
PCR was conducted in a thermocycler using the plasmid DNA of selected single colonies. It was carried out for examining the presence of the nptII and cry1AcF genes. The primers used for amplification of the nptII gene were 5'-GAGGCTATCAGCTGACTG-3' and 5'-TCGGGAGGCGATACCGTAGC-3', generating a 750 bp product and the primers for cry1AcF gene were 5'-AACCCCAACATCAACGGAGTGC -3' and 5'-TATGCGATCCAAAGATGCCC -3'resulting in a 664 bp product. The PCR reaction mixture (20µl) contained 0.3 U Taq DNA polymerase, 1X assay buffer (10 mM PH 9.0 Tris-HCl 50 mM Kcl, 1.5 mM MgCl2, 0.01% gelatin), 150 µM of each dNTPs, 1 µl of each forward and reverse primer at a final concentration of 0.25 µM, and a single colonies of bacteria.

The PCR reaction profile for cry1AcF gene comprised of 30 cycles, with strand separation at 94°C for 30 seconds annealing at 60°C for 30 seconds and extension at 72°C for 1 minute. The program was extended for 10minutes at 72°C. The PCR reaction profile for nptII gene comprised 32 cycles, with denaturation at 94°C for 1 min, annealing at 58°C for 1 minute 30 seconds and an extension at 72°C for 1minute, with final extension at 72°C for 10minutes. The PCR products were electrophoresed on a 1% agarose gel, stained with ethidium bromide, and visualized under transilluminator.

Agrobacterium mediated transformation of black gram with cry1AcF gene using Tissue culture dependent genetic transformation using cotyledony explants
Explant and Media preparation
Kanamycin sensitivity assay
For selection of transformed shoots an optimal concentration of kanamycin was determined by culturing non transformed (control) cotyledony explants on regeneration medium (MS + 3.0 mg/l BAP) containing various concentrations of kanamycin (15, 30, 50, 70, 90, 100, 120 mg/l). For each treatment, data on drying and survival percentage of explants were scored 2 to 3 weeks after initiation of culture.

Preparation of Agrobacterium culture
Agrobacterium bacterium strain EHA105 (pBinAR) was streaked on a YEP agar medium (10g yeast extract, 10g bacto peptone, 5g Nacl, 15g/l of agar, pH7.0). A single colony was transferred to 5 ml of YEP liquid medium with kanamycin (50 mg/l) and the culture was incubated at 28°C on a rotary shaker at 200 rpm from the overnight culture, 0.5 ml was transferred to 20 ml YEP liquid medium with kanamycin (50 mg/l). The culture was allowed to grow for 12 h. The culture was centrifuged at 3000 rpm for 10 minutes and the pellet resuspended in 20 ml of YEP liquid medium containing 100 µM acetosyringone at the density of 106cells/ml (OD600= 1) (Toriyama and Hinata 1985; Hiei et al., 1994).

Infection, cocultivation, and selection of transformants
The cotyledonal explants excised from 1-week-old seedlings were immersed in bacterial suspension for 20–25 min with occasional shaking. Inoculated explants were blotted on sterile filter paper and cocultured in Petri dishes containing co-cultivation medium (MS medium supplemented with 100 µM acetosyringone for 3 days under a 16 h photoperiod at 25 ± 2°C. After co-cultivation, the explants were washed three to four times with sterile distilled water and blotted dry on sterile filter paper. The explants were cultured on MS medium containing BAP (3 mg/l), 50 mg/l kanamycin, 400 mg/l cefotaxime and 0.8% agar for shoot regeneration. The explants were sub-cultured on fresh medium containing the same level of antibiotics every 2 weeks for 4–6 weeks. Green shoots recovered on selection medium were rooted on MS medium containing 0.5 mg/l NAA and 50 mg/l kanamycin. The putative transformed plants were established in soil and grown to maturity to collect to seeds.

Effect of kanamycin on black gram seeds of cv. VBN 3
For selection of transformed plants from explants an optimal concentration of kanamycin was determined cultivating the seeds on MS medium supplemented with different concentrations of kanamycin (15, 30, 50, 70, 90, 100, 120 mg/l). A total of twenty explants were used with five replications per treatment and the experiment was repeated thrice. For each treatment, data on drying and survival percentage of explants were scored 2 to 3 weeks after initiation of culture.

Preparation of Agrobacterium culture
Transformation via Sonication and Vacuum infiltration
The in planta transformation protocols in black gram genotypes using sonication and vacuum infiltration durations, and acetosyringone concentrations were followed according to Kapil dev et al. (2016) [3], with some slight modifications. The sterilized half-seed explants were transferred into Agrobacterium suspensions containing acetosyringone (100µM). Sonication was carried for 0, 1, 2, 3, 4, 5 and 6-min using a bath sonicator (model 1510 Branson, Branson Ultrasonics, Kanagawa, Japan). Then the seeds were transferred into fresh Agrobacterium suspension and subjected to vacuum infiltration for 0, 1, 2, 3, 4, 5 and 6-min at 750 mm of Hg using a desiccator (Tarsons, Kolkata, India) connected to a vacuum pump (Indian high vacuum pumps, Bangalore, India). The sonicated cum vacuum-infiltrated explants were incubated in Agrobacterium suspension medium supplemented with optimized concentration of acetosyringone 100 µM for 1 h under dark for Agrobacterium infection. Following this, the Agrobacterium infected seeds were blotted dry and then co-cultivated in MS medium without hormone containing 100 µM of acetosyringone for 3 dyas. The infected seeds were washed with sterile distilled water containing 500 mg/l cefotaxime (Alkem laboratories, Mumbai, India) and blot-dried on a sterilized filter paper and inoculated onto solid MS basal medium containing and
incubated at 25 ± 2 °C under 16 h photo period. The explants were sub-cultured twice at 5 days interval. After 4 weeks, the well rooted survival seedlings were transferred to earthen pots containing the potting mixture (1:1:1 of red soil, sand and farm yard manure) kept in greenhouse and maintained 85% relative humidity at 25 ± 2°C for acclimatization.

**Molecular analysis of putative transgenic plantlets**

The antibiotic resistant plants were subjected to molecular confirmation of the transgene using PCR with gene specific primers.

**DNA extraction**

Extraction of the DNA from the samples was carried out according to the procedures of Doyle and doyle (1990). Leaf tissue samples (2g) were collected from the putative transgenics of cotyledonary explants, and grinded in pestle and mortar by using pre heated (65°C) Cetyl Trimethyl Ammonium Bromide (CTAB) buffer. Around 15µl of CTAB buffer was added. Extracted samples were incubated in the water bath for 30 minutes at 65°C. After incubation equal volume of chloroform: isoamyl alcohol (24:1) was added in to the tubes and inverted for 5 to 10 min to mix. Then the tubes were kept in centrifuge for 10 minutes at 4000 rpm. Then the aqueous layer was transferred in to the new eppendorf tubes. An amount of equal volume of isopropanol (stored at -20°C) was added to each sample and inverted gently to mix and kept at overnight at 4°C. The samples were centrifuged at 10000 rpm for 10 minutes on the next day. The supernatant was discarded from each sample and the pellets settled in the bottom were air dried for 30 minutes. A quantity of 100 µl of TE buffer was added into each sample and stored it overnight at 4°C. RNAse (5µl) was added into each sample to exclude the RNA contamination and kept for incubation at 37°C for 30 minutes. An amount of equal volume of chloroform: isoamyl alcohol (24:1) was added to the tubes and centrifuged at 1000 rpm for 5 minutes and the supernatant was taken into the fresh tubes. To which the twice the volume of absolute ethanol and 1/10th volume of 3M sodium acetate was added and kept the samples at -70°C for 1 hour. Centrifuge the tubes at 10000 rpm for 10 minutes. The supernatant was discarded and 200 µl of 70% ethanol was added and centrifuged at 5000 rpm for 5 minutes. The supernatant was discarded and the pellet was air dried for 30 minutes. The pellet was resuspended by using 100 µl TE buffer and kept at -20°C for long term use.

**DNA quality and quantity estimation**

The concentration of DNA was estimated spectrophotometrically. In spectrophotometric analysis, 5 µl of DNA was diluted to 3000 µl of TE buffer. The spectrophotometer readings were recorded at 260 and 280 nm. DNA concentration was calculated using OD values at 260 nm using the following formula concentration of DNA (µl/ml) = OD at 260 nm X 50.

*Agrobacterium* mediated in planta transformation of black gram cv. VBN-3 through Sonication and vacuum infiltration.
PCR analysis

Reactions were performed in a final volume of 25 µl and the mixture contained 50 ng of genomic DNA, 2.5 µl of 10X PCR buffer (10 mM Tris-HCl pH 9.0, 50 mM KCl, 1.5 mM MgCl₂, 0.001% (w/v) gelatin), 200 mM of each of dNTPs, 70 ng of upstream and downstream primers and 2 units of *Taq* DNA polymerase. Amplification was performed in a thermocycler (Mastercycler Personal, Eppendorf, USA).

**cry1AcF**

Forward primer (5’- GAGGCTATTCGCTATGACTG-3’) and reverse primer (5’- ATCGGGAGGGCAGATCCGTA-3’) were used to amplify a 750 bp long fragment of the *cry1AcF* gene. The PCR reaction profile for *cry1AcF* gene comprised 30 cycles, with strand separation at 94°C for 30 seconds, annealing at 60°C for 30 seconds, and extension at 72°C for 1 minute. The program was extended for 10 minutes at 72°C. After amplification, 10µl of the product was used for electrophoretic analysis on 1.5% agarose gels.

**nptII**

Forward primer (5’- AACCCAAAATCAACGAGTGC -3’) and reverse primer (5’- TTATGCAGTCCAAGATGTC -3’) were used to amplify a 664 bp long fragment of *cry1AcF*. The PCR reaction profile for *cry1AcF* gene comprised of 30 cycles, with strand separation at 94°C for 30 seconds, annealing at 60°C for 30 seconds, and extension at 72°C for 1 minute. The program was extended for 10 minutes at 72°C. After amplification, 10µl of the product was used for electrophoretic analysis on 1.5% agarose gels.
Table 4: Effect of kanamycin concentration on survival and adventitious shoot initiation from 1-week-old cotyledons of black gram cv. VBN 3.

| Kanamycin concentration (mg/l) | No. of cotyledons/ treatment | No. of cotyledons survived | Survival % | Shoot initiation |
|-------------------------------|------------------------------|----------------------------|------------|------------------|

* - explants on section medium (MS + kanamycin 50 mg/l)

Results and Discussion

It is mandatory to develop genetically engineered black gram cultivars. Legumes particularly V. mungo, are extremely recalcitrant to in vitro culture and genetic transformation. In the particle bombardment method, germinated embryos of black gram were used as explant (Bhargava and Smigocki 1994). Although the previous reports showed positive results in black gram transformation, many constraints still exist to limit the improvement of black gram with desirable traits.
Vamban 3 an Indian black gram cultivar was selected for this study. In the present study 50 mg/l kanamycin concentration in the medium caused a drastic decrease in both the frequency of regeneration and number of shoots per explant, hence this concentration was used for the selection of transformed shoots. Using nptII as a selectable marker gene and kanamycin as a selection agent is widely used system for screening trans formants in a large variety of plants like mulberry (Bhatnagar and Khurana, 2003) [3], chickpea (Mehrotra et al. 2011) [6]. Here, also we used the same selectable marker and were able to achieve complete suppression of non-transformed plants with optimized dose of kanamycin (50 mg/l). The identification and development of cry genes in transgenic crops for pest management has turned out to be a major accomplishment. A major limitation has been specificity of the Bt toxins to only a certain group of lepidopterans pests.

In planta transformation a single colony from Agrobacterium tumefaciens strains was inoculated separately into 30ml YEP medium amended with the aforementioned antibiotics and incubated at 28 °C in an orbital shaker set at 180 rpm (Ganapathi et al., 2015). Following co-cultivation, the infected seeds were washed with sterile liquid MS medium containing cefotaxime (Alkem laboratories, Mumbai, India). They were then blot-dried on a sterilized filter paper and inoculated onto solid MS basal medium. A total of surviving plants of transformation were used for confirmation of putative transgenic lines by PCR analysis using gene specific primers cry1AcF and nptII. However the PCR analysis in 10 selected putative plantlets of blackgram did not shown amplification for cry1AcF and nptII genes. This indicates no transgenic shoots were obtained in this study. These results are negatively correlated with the previous works of Ganapathi et al., 2016; Saini and Jaival et al., 2003; Jaival et al., 2005, where they have achieved transformation efficiency of 46.2%, 2.05% and 17% respectively. The transformation efficiency (0.0%) in the present study may be due to the usage of the cotyledons explants excised from 7 days old seedlings. Future line of research is needed to generate huge number of stable transgenic plants by employing different dilution of overnight bacterial culture (1:10, 1:25, 1:50 and 1:100) to improve regeneration efficiency. In another in planta experiment, presoaked seeds with just emerging plumule were infected by pricking using sterile needle and incubated in Agrobacterium culture. Out of 30 seeds that were subjected to Agrobacterium infection, 20 plantlets that survived the infection process were transferred to the greenhouse.

To sum up biotechnological approaches for the improvement of black gram for growth and yield parameters is a continuous parameter to be assessed. In the present study investigation, genetic transformation using Agrobacterium mediated in planta transformation methods we attempted to evaluate the best methodology for reliable protocol development. Regeneration attempts using different sources of cytokinins indicated BAP is the best. Nevertheless these attempts need to be refined and approached with still better methodologies which will open up new vistas in the era of black gram transformation and molecular breeding techniques.
