REFINING THE TAMING OF THE REVERSE MATHEMATICS ZOO

SAM SANDERS

Abstract. Reverse Mathematics is a program in the foundations of mathematics. It provides an elegant classification in which the majority of theorems of ordinary mathematics fall into only five categories, based on the ‘Big Five’ logical systems. Recently, a lot of effort has been directed towards finding exceptional theorems, i.e. which fall outside the Big Five. The so-called Reverse Mathematics zoo is a collection of such exceptional theorems (and their relations). It was shown in [17] that a number of uniform versions of the zoo-theorems, i.e. where a functional computes the objects stated to exist, fall in the third Big Five category arithmetical comprehension, inside Kohlenbach’s higher-order Reverse Mathematics. In this paper, we extend and refine the results from [17]. In particular, we establish analogous results for recent additions to the Reverse Mathematics zoo, thus establishing that the latter disappear at the uniform level. Furthermore, we show that the aforementioned equivalences can be proved using only intuitionistic logic. Perhaps most surprisingly, these explicit equivalences are extracted from nonstandard equivalences in Nelson’s internal set theory, and we show that the nonstandard equivalence can be recovered from the explicit ones. Finally, the following zoo-theorems are studied in this paper: Π₀¹ G (existence of uniformly Π₀¹ generics), FIP (finite intersection principle), 1-GEN (existence of 1-generics), OPT (omitting partial types principle), AMT (atomic model theorem), SADS (stable ascending or descending sequence), AST (atomic model theorem with sub-enumerable types), NCS (existence of non-computable sets), and KPT (Kleene/Post theorem that there exist Turing incomparable sets).

1. Introduction: Reverse Mathematics and its zoo

The subject of this paper is the Reverse Mathematics classification in Kohlenbach’s framework ([13]) of uniform versions of principles from the Reverse Mathematics zoo ([8]), namely as equivalent to arithmetical comprehension. A number of theorems from the Reverse Mathematics zoo have been classified in this way in [17], and this paper continues and refines this classification. We first discuss the aforementioned italicised notions in more detail.

First of all, an overview of the foundational program Reverse Mathematics (RM for short), may be found in [19, 20]. Perhaps the main conceptual result of RM is that the majority of theorems from ordinary mathematics, i.e. about countable and separable objects, fall into only five classes of which the associated logical systems...
have been christened ‘the Big Five’ (See e.g. [14, p. 432] and [10, p. 69] for this point of view). Recently, considerable effort has been spent identifying theorems falling outside of the Big Five systems. For an overview, exceptional theorems (and their relations) falling below the third Big Five system ACA₀, are collected in Dzhafarov’s so-called RM zoo ([8]).

It was established in [17] that a number of exceptional principles inhabiting the RM zoo become non-exceptional at the uniform level, namely that the uniform versions of RM zoo-principles are all equivalent to arithmetical comprehension, the aforementioned third Big Five system of RM. As an example of such a ‘uniform version’, consider the principle UDNR from [17, §3].

\[(\exists \Psi^{1\to 1})[(\forall A^1)(\forall e^0)(\Psi(A)(e) \neq \Phi^A_e(e))]\].  \hspace{1cm} (UDNR)

Clearly, UDNR is the uniform version of the zoo principle DNR, defined as:

\[(\forall A^1)(\exists f^1)(\forall e^0)[f(e) \neq \Phi^A_e(e)]\]. \hspace{1cm} (DNR)

Now, the principle DNR was introduced in [9] and is strictly weaker than WWKL (See [1]) where the latter principle sports a small number of Reverse Mathematics equivalences ([14,23,24]), but is not counted as a ‘Big Five’ system. The exceptional status of DNR notwithstanding, it was shown in [17, §3] that UDNR \(\leftrightarrow (\exists^2)\), where the second principle is the functional version of arithmetical comprehension, the third Big Five system of RM, defined as follows:

\[(\exists \phi^2)(\forall f^1)(\phi(f) = 0 \leftrightarrow (\exists n)f(n) \neq 0)\]. \hspace{1cm} (\exists^2)

In other words, the ‘exceptional’ status of DNR disappears completely if we consider its uniform version UDNR. Furthermore, the proof of the equivalence UDNR \(\leftrightarrow (\exists^2)\) takes place in \(\text{RCA}_0^\omega\) (See Section 2), the base theory of Kohlenbach’s higher-order Reverse Mathematics. This system is a conservative extension of \(\text{RCA}_0\), the usual base theory of RM, for the second-order language.

More generally, a number of uniform zoo-principles are shown to be equivalent to arithmetical comprehension over \(\text{RCA}_0^\omega\) in [17]. A general template for classifying (past and future) zoo-principles in the same way was also formulated in the latter. In Section 3, we show that this template works for a number of new theorems from the RM zoo, and refine the associated results considerably, as discussed next.

The methodology by which the aforementioned equivalences are obtained, constitutes somewhat of a surprise: In particular, the equivalences in this paper are formulated as theorems of Kohlenbach’s base theory \(\text{RCA}_0^\omega\) (See [13] and Section 2.2), but are obtained by applying the algorithm \(\mathcal{RS}\) (See Section 2.4) to associated equivalences in Nonstandard Analysis, in particular Nelson’s internal set theory (See [15] and Section 2.1). Besides providing a streamlined and uniform approach, the use of Nonstandard Analysis via \(\mathcal{RS}\) also results in explicit equivalences without extra effort. In particular, we shall just prove equivalences inside Nonstandard Analysis without paying any attention to effective content, and extract the explicit equivalences using the algorithm \(\mathcal{RS}\). This new ‘computational aspect’ of Nonstandard Analysis is perhaps the true surprise of our taming of the RM zoo.

---

1 We sometimes refer to inhabitants of the RM zoo as ‘theorems’ and sometimes as ‘principles’.
2 An implication \((\exists \Psi)(A(\Phi) \rightarrow (\exists \Psi)B(\Psi))\) is explicit if there is a term \(t\) in the language such that additionally \((\forall \Psi)(A(\Phi) \rightarrow B(t(\Phi)))\), i.e. \(\Psi\) can be explicitly defined in terms of \(\Phi\).
The following zoo-theorems are studied in Section 3 in the aforementioned way: $\Pi^0_1 \text{G}$ (existence of uniformly $\Pi^0_1$-generics), FIP (finite intersection principle), 1-GEN (existence of 1-generics), OPT (omitting partial types principle), AMT (atomic model theorem), SADS (stable ascending or descending sequence), AST (atomic model theorem with sub-enumerable types), NCS (existence of non-computable sets), and KPT (Kleene/Post theorem that there exist Turing incomparable sets).

Furthermore, we shall refine the results from [17] and Section 3 of this paper as follows in Section 4: First of all, while all results sketched above are proved using classical logic, we show in Section 4.1 that they also go through for intuitionistic logic. Secondly, we formulate in Section 4.2 a special kind of explicit equivalence, called Herbrandisation, from which we can re-obtain the original equivalence in Nonstandard Analysis. In other words, the Herbrandisation is ‘meta-equivalent’ to the nonstandard implication from which it was extracted.

In conclusion, this paper continues and refines the ‘taming of the RM zoo’ initiated in [17], i.e. we establish the equivalence between uniform RM zoo principles and arithmetical comprehension using intuitionistic logic. Furthermore, thanks to a new computational aspect of Nonstandard Analysis, we obtain ‘for free’ explicit equivalences (not involving Nonstandard Analysis) from (non-effective) equivalences in Nonstandard Analysis, and vice versa.

2. About and around internal set theory

In this section, we introduce Nelson’s internal set theory, first introduced in [15], and its fragment $\text{P}$ from [3]. We shall also introduce Kohlenbach’s base theory $\text{RCA}_{\omega}^0$ from [13], and the system $\text{RCA}_{\omega}^\Lambda$, which is based on $\text{P}$. These systems are also introduced in [17, §2], but we include their definitions for completeness.

2.1. Introduction: Internal set theory. In Nelson’s syntactic approach to Nonstandard Analysis ([15]), as opposed to Robinson’s semantic one ([16]), a new predicate ‘st($x$)’, read as ‘$x$ is standard’ is added to the language of ZFC, the usual foundation of mathematics. The notations ($\forall \text{st } x$) and ($\exists \text{st } y$) are short for ($\forall x$)(st($x$) $\rightarrow$ ...) and ($\exists y$)(st($y$) $\land$ ...). A formula is called internal if it does not involve ‘st’, and external otherwise. The three external axioms Idealisation, Standard Part, and Transfer govern the new predicate ‘st’; they are introduced in Definition 2.1 below, where the superscript ‘fin’ in (I) means that $x$ is finite, i.e. its number of elements are bounded by a natural number.

Definition 2.1. [External axioms of IST]

(I) ($\forall^{\text{st fin}_x}x$)($\exists y$)($\forall z \in x$)$\varphi(z,y)$ $\rightarrow$ ($\exists y$)($\forall^{\text{st}_x}x$)$\varphi(x,y)$, for internal $\varphi$ with any (possibly nonstandard) parameters.

(S) ($\forall^{\text{st}_x}x$)($\exists^{\text{st}_y}y$)($\forall^{\text{st}_z}z$)($z \in y \leftrightarrow (z \in y \land \varphi(z))$), for any formula $\varphi$.

(T) ($\forall^{\text{st}_t}t$)[$($($\forall^{\text{st}_x}x$)$\varphi(x,t)$ $\rightarrow$ ($\forall x$)$\varphi(x,t)$)$\land$ where $\varphi$ is internal and only has free variables $t,x$.

The system IST is (the internal system) ZFC extended with the aforementioned external axioms. Furthermore, IST is a conservative extension of ZFC for the internal language, as proved in [15].

---

3An implication ($\exists \Phi$)$A(\Phi) \rightarrow (\exists \Psi)B(\Psi)$ is explicit if there is a term $t$ in the language such that additionally ($\forall \Phi$)$A(\Phi) \rightarrow B(t(\Phi))$, i.e. $\Psi$ can be explicitly defined in terms of $\Phi$. 
In [3], the authors study Gödel’s system $T$ extended with special cases of the external axioms of IST. In particular, they consider nonstandard extensions of the (internal) systems $E$-$HA^\infty$ and $E$-$PA^\infty$, respectively Heyting and Peano arithmetic in all finite types and the axiom of extensionality. We refer to [3, §2.1] for the exact details of these (mainstream in mathematical logic) systems. We do mention that in these systems of higher-order arithmetic, each variable $x^\rho$ comes equipped with a superscript denoting its type, which is however often implicit. As to the coding of multiple variables, the type $\rho^*$ is the type of finite sequences of type $\rho$, a notational device used in [3] and this paper. Underlined variables $x$ consist of multiple variables of (possibly) different type.

In the next section, we introduce the system $P$ assuming familiarity with the higher-type framework of Gödel’s system $T$ (See e.g. [3, §2.1] for the latter).

2.2. The system $P$. In this section, we introduce the system $P$. We first discuss some of the external axioms studied in [3]. First of all, Nelson’s axiom Standard part is weakened to $\text{HAC}_{\text{int}}$ as follows:

$$(\forall^\ast x^\rho)(\exists^\ast y^\tau)(\forall y^\tau)(\exists^\ast x^\rho)(\exists y^\tau \in F(x)) \varphi(x, y), \quad (\text{HAC}_{\text{int}})$$

where $\varphi$ is any internal formula. Note that $F$ only provides a finite sequence of witnesses to $(\exists^\ast y)$, explaining its name Herbrandized Axiom of Choice. Secondly, Nelson’s axiom idealisation $I$ appears in [3] as follows:

$$(\forall^\ast x^\rho)(\exists y^\tau)(\forall z^\sigma \in x) \varphi(z, y) \rightarrow (\exists y^\tau)(\forall^\ast x^\rho)\varphi(x, y), \quad (1)$$

where $\varphi$ is again an internal formula. Finally, as in [3, Def. 6.1], we have the following definition.

**Definition 2.2.** The set $T^*$ is defined as the collection of all the constants in the language of $E$-$PA^\infty$. The system $E$-$PA^\infty_{\text{st}}$ is defined as $E$-$PA^\infty + T^*_{\text{st}} + \text{IA}^{\text{st}}$, where $T^*_{\text{st}}$ consists of the following axiom schemas.

1. The schema $(\text{st}(x) \wedge x = y \rightarrow \text{st}(y))$.
2. The schema providing for each closed term $t \in T^*$ the axiom $\text{st}(t)$.
3. The schema $\text{st}(f) \wedge \text{st}(x) \rightarrow \text{st}(f(x))$.

The external induction axiom $\text{IA}^{\text{st}}$ is as follows.

$$\Phi(0) \land (\forall^\ast n^0)(\Phi(n) \rightarrow \Phi(n + 1)) \rightarrow (\forall^\ast n^0)\Phi(n). \quad (\text{IA}^{\text{st}})$$

For the full system $P \equiv E$-$PA^\infty_{\text{st}} + \text{HAC}_{\text{int}} + I$, we have the following theorem. Here, the superscript ‘$S_{\text{st}}$’ is the syntactic translation defined in [3, Def. 7.1].

**Theorem 2.3.** Let $\Phi(\underline{a})$ be a formula in the language of $E$-$PA^\infty_{\text{st}}$ and suppose $\Phi(\underline{a})^{S_{\text{st}}} \equiv \forall^\ast x \exists y \varphi(x, y, \underline{a})$. If $\Delta_{\text{int}}$ is a collection of internal formulas and

$$P + \Delta_{\text{int}} \vdash \Phi(\underline{a}), \quad (2.1)$$

then one can extract from the proof a sequence of closed terms $t$ in $T^*$ such that

$$E$-$PA^\infty_{\text{st}} + \Delta_{\text{int}} \vdash \forall x \exists y \in \mathcal{L}(x) \varphi(x, y, \underline{a}). \quad (2.2)$$

**Proof.** Immediate by [3, Theorem 7.7]. \qed
It is important to note that the proof of the soundness theorem in [3 §7] provides a term extraction algorithm $A$ to obtain the term $t$ from the theorem.

The following corollary is essential to our results. We shall refer to formulas of the form $(\forall^\ast x)(\exists^\ast y)\psi(x, y, a)$ for internal $\psi$ as (being in) the normal form.

**Corollary 2.4.** If for internal $\psi$ the formula $\Phi(a) \equiv (\forall^\ast x)(\exists^\ast y)\psi(x, y, a)$ satisfies (2.1), then $(\forall x)(\exists y \in t(x))\psi(x, y, a)$ is proved in the corresponding formula (2.2).

**Proof.** Clearly, if for $\psi$ and $\Phi$ as given we have $\Phi(a)^{S_{\ast}} \equiv \Phi(a)$, then the corollary follows immediately from the theorem. A tedious but straightforward verification using the clauses (i)-(v) in [3 Def. 7.1] establishes that indeed $\Phi(a)^{S_{\ast}} \equiv \Phi(a)$. This verification is performed in full detail in [17 §2] and [18].

Finally, the previous theorems do not really depend on the presence of full Peano arithmetic. Indeed, let E-PRA$^\ast$ be the system defined in [13 §2] and let E-PRA$^{\ast \ast}$ be its extension with types for finite sequences as in [3 §2].

**Corollary 2.5.** The previous theorem and corollary go through for $P$ replaced by $P_0 \equiv E$-PRA$^{\ast \ast} + T_0^\ast + HAC_{\ast \ast} + 1$.

**Proof.** The proof of [3 Theorem 7.7] goes through for any fragment of E-PRA$^{\ast \ast}$ which includes EFA, sometimes also called $\Delta_0 + \text{EXP}$. In particular, the exponential function is (all what is) required to ‘easily’ manipulate finite sequences.

Finally, we define RCA$^\Lambda_0$ as the system $P_0 + \text{QF-AC}^{1,0}$. Recall that Kohlenbach defines RCA$^\rho_0$ in [13 §2] as E-PRA$^\ast + \text{QF-AC}^{1,0}$ where the latter is the axiom of choice limited to formulas $(\forall f^\ast)((\exists^\ast n^\ast))\phi_0(f, n)$, $\phi_0$ quantifier-free.

### 2.3. Notations and remarks.

We introduce some notations regarding RCA$^\Lambda_0$. First of all, we shall mostly follow Nelson’s notations as in [4].

**Remark 2.6** (Standardness). As suggested above, we write $(\forall^\ast x^\tau)\Phi(x^\tau)$ and also $(\exists^\ast x^\tau)\Psi(x^\rho)$ as short for $(\forall x^\tau)[st(x^\tau) \to \Phi(x^\tau)]$ and $(\exists x^\tau)[st(x^\tau) \land \Psi(x^\rho)]$. We also write $(\forall x^0 \in \Omega)\Phi(x^0)$ and $(\exists x^0 \in \Omega)\Psi(x^0)$ as short for $(\forall x^0)[\neg st(x^0) \to \Phi(x^0)]$ and $(\exists x^0)[\neg st(x^0) \land \Psi(x^0)]$. Furthermore, if $\neg st(x^0)$ (resp. $st(x^0)$), we also say that $x^0$ is ‘infinite’ (resp. ‘finite’) and write ‘$x^0 \in \Omega$’. Finally, a formula $A$ is ‘internal’ if it does not involve ‘st’, and $A^\ast$ is defined from $A$ by appending ‘st’ to all quantifiers (except bounded number quantifiers).

Secondly, the notion of equality in RCA$^\Lambda_0$ is important to our enterprise.

**Remark 2.7** (Equality). The system RCA$^\rho_0$ includes equality between natural numbers ‘$=^0$’ as a primitive. Equality ‘$=^\tau$’ for type $\tau$-objects $x, y$ is defined as follows:

$$[x =^\tau y] \equiv (\forall z_1^\tau \ldots z_k^\tau)(x z_1 = 0 y z_1 \ldots z_k)
\quad (2.3)$$

if the type $\tau$ is composed as $\tau \equiv (\tau_1 \to \ldots \to \tau_k \to 0)$. In the spirit of Nonstandard Analysis, we define ‘approximate equality $\approx^\tau$’ as follows:

$$[x \approx^\tau y] \equiv (\forall z_1^\tau \ldots z_k^\tau)(x z_1 \ldots z_k = 0 y z_1 \ldots z_k)
\quad (2.4)$$

with the type $\tau$ as above. Furthermore, the system RCA$^\rho_0$ includes the axiom of extensionality as follows:

$$(\forall \varphi^{0 \to \tau})(\forall x^\rho, y^\rho)[x =^\rho y \to \varphi(x) =^\tau \varphi(y)].
\quad (E)$$
However, as noted in [3] p. 1973, the axiom of standard extensionality (E) cannot be included in the system P (and hence RCA₀). Finally, a functional Ξ is called the following steps: (Let Template. Thirdly, with these definitions in place, our template is formulated as follows.

Definition 2.8. [Explicit implication] An implication (∃Π)A(Φ) → (∃Ψ)B(Ψ) is explicit if there is a term t in the language such that additionally (∀ψ)[A(Φ) → B(t(Φ))], i.e. Ψ can be explicitly defined in terms of Φ.

Given that an extensionality functional as defined in Remark 2.7 amounts to nothing more than an unbounded search, an implication as in the previous definition will still be called ‘explicit’ if the term t additionally involves an extensionality functional Ξ for Φ as defined in (2.5).

Secondly, we need the following functional version of arithmetical comprehension, called Feferman’s non-constructive search operator (See e.g. [2 §8.2]):

(∃²µ)(∀f¹)((∃µ⁰)f(n) = 0 → f(µ(f)) = 0),

(µ²)
equivalent to (3²) over RCA₀ by [13, Prop. 3.9]. We also require the following special case of the 1ST axiom Transfer:

(∀²¹μ¹)((∃µ⁰)f(n) = 0 → (∃²¹m⁰)f(m) = 0).

(Π¹⁻¹, TRANS)

Thirdly, with these definitions in place, our template is formulated as follows.

Template. Let T ≡ (∀X¹)(∃Y¹)φ(X,Y) be a RM zoo principle and let UT be (∃³¹Φ¹⁻¹)(∀X¹)φ(X, Φ(X)). To prove the explicit implication UT → (μ²), execute the following steps:

(i) Let UT⁺ be (∃³¹Φ¹⁻¹)(∀X¹)φ(X, Φ(X)) where the functional Φ is additionally standard extensional. We work in RCA₀ + UT⁺.
(ii) Suppose the standard function h¹ is such that (∃¹h(n) = 0 and (∃m)h(m) ≠ 0, i.e. h is a counterexample to Π¹⁻¹, TRANS.
(iii) For standard V¹, use h to define standard W¹ ≈₁ V such that Φ(W) ≠₁ Φ(V), i.e. W is V with the nonstandard elements changed sufficiently to yield a different image under Φ.
(iv) The previous contradiction implies that RCA₀ proves UT⁺ → Π¹⁻¹, TRANS.
(v) Bring the implication from the previous step into the normal form (∃¹x)(∃²y)ψ(x,y) (ψ internal) using the algorithm B from Remark 3.5.
(vi) Apply the term extraction algorithm A using Corollary 2.5. The resulting term yields the explicit implication UT → (μ²).
The explicit implication \((\mu^2) \rightarrow UT\) is usually straightforward; alternatively, establish \(\Pi^1_0\)-TRANS \(\rightarrow UT^+\) in \(\text{RCA}_0^\Lambda\) and apply steps (vi) and (vii).

The algorithm \(\mathfrak{A}\mathfrak{S}\) is defined as the steps (vi) and (vii) in the template, i.e. the application of the algorithms \(\mathcal{B}\) and \(\mathcal{A}\) to suitable implications.

By way of example, the following theorem was established in [17, §3], where \(\text{UDNR}(\Psi)\) and \(\text{MU}(\mu)\) are \(\text{UDNR}\) and \((\mu^2)\) without the leading existential quantifier.

**Theorem 2.9.** From the proof of \(\text{UDNR}^+ \iff \Pi^0_1\)-TRANS in \(\text{RCA}_0^\Lambda\), two terms \(s, u\) can be extracted such that \(\text{RCA}_0^\Lambda\) proves:

\[
(\forall \mu^2)[\text{MU}(\mu) \rightarrow \text{UDNR}(s(\mu)) \land (\forall \Psi^{1\rightarrow 1})]\left(\text{UDNR}(\Psi) \rightarrow \text{MU}(u(\Psi, \Phi))\right), \quad (2.6)
\]

where \(\Phi\) is an extensionality functional for \(\Psi\).

From this theorem, we may conclude that \(\text{RCA}_0^\Lambda\) proves \(\text{UDNR} \iff (\mu^2)\), and that this equivalence is ‘explicit’ as in Definition 2.8.

Finally, the above template treats zoo-principles in a kind of ‘\(\Pi^1_2\)-normal form’, for the simple reason that most zoo-principles are formulated in such a way. Nonetheless, it is a natural question, discussed in [17, §6], whether principles not formulated in this normal form gives rise to uniform principles not equivalent to \((\mu^2)\). Surprisingly, the answer to this question turned out to be negative.

## 3. Classifying the RM zoo

In this section, we apply the template from Section 2.4 to a number of new theorems from the RM zoo. In each case, we show that the uniform version of the RM zoo principle is (explicitly) equivalent to arithmetical comprehension.

### 3.1. Universal genericity

In this section, we study the principle \(\Pi^1_0 G\) from [11, §4] and [10, Def. 9.44], which is the statement that for every collection of uniform \(\Pi^0_1\)-dense predicates on \(2^{\omega}\), there is a sequence in \(2^{\omega}\) meeting all predicates. Like in [3], we use the notation \(\sigma^{\omega^*} \leq_0 1\) to denote that \(\sigma\) is a finite binary sequence.

**Principle 3.1 (\(\Pi^1_0 G\)).** Define \(D_1(\sigma) \equiv \varphi(i, \sigma)\) with \(\varphi \in \Pi^1_0\). We have

\[
(\forall i^0)(\forall^\sigma \leq_0 1)(\exists^\sigma \geq \tau)D_1(\sigma) \rightarrow (\exists G^1 \leq_1 1)(\forall i^0)(\exists^\sigma \prec G^1 \varphi G 1)D_1(\sigma).
\]

The ‘fully’ uniform version of \(\Pi^1_0 G\) is then defined as follows. Note the function \(g^1\) which realise the antecedent of \(\Pi^1_0 G\) and the function \(\Phi(f, g)(2)\) which realises the numerical quantifier in the consequent of \(\Pi^1_0 G\).

**Principle 3.2 (\(\text{UII}^1_0 G\)).** Define \(D_1^1(\sigma) \equiv (\forall k^0)f(k, i, \sigma) \neq 0\). There is \(\Phi^{(1 \times 1)} \rightarrow (1 \times 1)^1\) such that for all \(f^1, g^1\)

\[
(\forall i^0)(\forall^\sigma \leq_0 1)[g(i, \tau) \geq \tau \land D_1^1(g(i, \tau)) \rightarrow (\forall i^0)[\Phi(f, g)(2)(i) \prec \Phi(f, g)(1))] \land D_1^1(\Phi(f, g)(2)(i))]
\]

\[
(3.1)
\]

**Theorem 3.3.** In \(\text{RCA}_0^\Lambda\), we have \(\text{UII}^1_0 G \iff (\mu^2)\), and this equivalence is explicit.

**Proof.** The reverse implication is immediate as \(\text{ACA}_0\) implies \(\text{UII}^1_0 G\) and \((\mu^2)\) easily (and explicitly) yields \(\text{UII}^1_0 G\) as all relevant notions are arithmetical. We will now apply the template from Section 2.4 to obtain the explicit implication \(\text{UII}^1_0 G \rightarrow (\mu^2)\).

Working in \(\text{RCA}_0^\Lambda + \text{UII}^1_0 G^+\), suppose \(\neg \Pi^0_1\)-TRANS, i.e. there is a function \(h\) such that \((\forall x^0)n^0(h(n) = 0 \land (\exists m^0)h(m) \neq 0). Recall from Section 2.4 that \(\text{UII}^1_0 G^+\)
expresses that UIP₀G holds, and the functional Φ in the latter is standard and standard extensional. Now let \( f^1, g^1 \) be standard functions such that the antecedent of (3.1) holds. Define the standard function \( g_0 \) as follows:

\[
g_0(i, \tau) := \begin{cases} 
  g(i, \tau \ast \langle k \rangle) & \tau \prec \Phi(f, g)(1) \land (\exists n \leq \lvert \tau \rvert) h(n) \neq 0 \land k \leq 1 \text{ is the least such that } \tau \ast \langle k \rangle \neq \Phi(f, g)(1) \\
  g(i, \tau) & \text{otherwise}
\end{cases}
\]

By the definition of \( g_0 \), we still have \( (\forall^0)(\forall^0 \leq 0) [g_0(i, \tau) \geq \tau \land D_i^0 \langle g_0(i, \tau) \rangle] \).

Furthermore define the standard function \( f_0 \) as follows:

\[
f_0(k, i, \tau) := \begin{cases} 
  f(k, i, \tau) & (\forall n \leq \max(\lvert \tau \rvert, \lvert k \rvert))(h(n) = 0) \lor \tau \neq \Phi(f, g)(1) \\
  0 & \text{otherwise}
\end{cases}
\]

Intuitively speaking, \( f_0 \) is just \( f \) with (long enough) initial segments of \( \Phi(f, g)(1) \) mapping to zero. Nonetheless, by the definition of \( f_0, g_0 \), we still have

\[
(\forall^0)(\forall^0 \leq 0) [f_0(i, \tau) \geq \tau \land D_i^{f_0} \langle f_0(i, \tau) \rangle],
\]

as the modification to \( g \) in (3.2) is such that ‘too long’ initial segments of \( \Phi(f, g)(1) \) are never output by \( g_0 \). Since \( f \approx_{\Pi^1_1} f_0 \) and \( g \approx_{\Pi^1_1} g_0 \), standard extensionality implies:

\[
\Phi(f, g) \approx_{1 \times 1} \Phi(f_0, g_0) \approx_{1 \times 1} \Phi(f_0, g_0). 
\]

Applying UIP₀\( \mathbf{G} \) for \( f_0, g_0 \), we obtain for any \( i \):

\[
\Phi(f_0, g_0)(2)(i) \prec \Phi(f_0, g_0)(1) \land D_i^{f_0} \langle \Phi(f_0, g_0)(2)(i) \rangle, 
\]

and by standard extensionality (3.3), we have \( \Phi(f_0, g_0)(2)(i) =_0 \Phi(f, g)(2)(i) \) and also \( \Phi(f, g)(1) \approx_{1} \Phi(f_0, g_0)(1) \) for standard \( i \). However, now consider the second conjunct of (3.4), which is \( (\forall k^0) f_0(k, i, \Phi(f_0, g_0)(2)(i)) \neq 0 \). For large enough \( k \) and standard \( i \), we are in the second case of the definition of \( f_0 \) as \( (\forall f_0, g_0)(2)(i) \prec \Phi(f_0, g_0)(1) \approx_{1} \Phi(f, g)(1) \), by standard extensionality, the first conjunct of (3.4), and the fact that \( \Phi(f_0, g_0)(2)(i) \) is standard. However, the second conjunct of (3.4) contradicts the second case of \( f_0 \), and this contradiction implies \( \Pi^1_1\text{-TRANS} \).

Hence, we have established \( UIP_0^G \rightarrow \Pi^1_1\text{-TRANS} \) inside \( RCA_0^\ast \). We now bring the former implication into normal form; first of all, note that \( \Pi^1_1\text{-TRANS} \) implies

\[
(\forall^0 f^1)(\exists^0 m^0)(\forall^0)f(n) \neq 0 \rightarrow (\exists i \leq m)f(i) \neq 0,
\]

which is a normal form, and where \( C(f, m) \) is the formula in square brackets in (3.5). Furthermore, \( UIP_0^G \) has the form

\[
\exists^0 \Phi \left[ (\forall^0 f^1, g^1) A(f, g, \Phi) \land \Phi \text{ is standard extensional} \right],
\]

where \( A(f, g, \Phi) \) is exactly (3.1). The second conjunct of (3.6) is:

\[
(\forall^0 f^1, g^1, u^1, v^1)(u \approx_{1} v \land f \approx_{1} g \rightarrow \Phi(f, g)(1) \approx_{1 \times 1} \Phi(u, v)(1)).
\]

Resolving all instances of ‘\( \approx_{1} \)’, we obtain that for all standard \( f^1, g^1, u^1, v^1 \):

\[
(\forall^0 N^0)(\forall N =_0 \forall N \land \forall N =_0 \forall N) \rightarrow (\forall i \leq 1)(\exists^0 k^0)(\Phi(f, g)(i)k =_0 \Phi(u, v)(i)k).
\]

Bringing all standard quantifiers outside, we obtain

\[
(\forall^0 f^1, g^1, u^1, v^1, k^0, i^0 \leq 1)(\exists^0 N^0) B(f, g, u, v, k, i, N, \Phi),
\]

where \( B \) is the formula

\[
(\forall N =_0 \forall N \land \forall N =_0 \forall N) \rightarrow (\Phi(f, g)(i)k =_0 \Phi(u, v)(i)k).
\]
Combining all the previous, \( \text{UIP}_0^1 \rightarrow \Pi^1_0 \text{-TRANS} \) implies that
\[
[(\exists^* \Phi)[(\forall^* h, g^1) A(h, g, \Phi) \land (\forall^* Z^1)(\exists^* N^0) B(Z, N, \Phi)] \rightarrow (\forall^* f^1)(\exists^* m^0) C(f, m),
\]
where \( Z^1 \) codes all the variables in the leading quantifier of (3.7). This yields
\[
(\forall^* \Phi, \Xi)[[(\forall^* h, g^1) A(h, g, \Phi) \land (\forall^* Z^1) B(Z, \Xi(Z), \Phi)] \rightarrow (\forall^* f^1)(\exists^* m^0) C(f, m)],
\]
and dropping some ‘\( t \)’ and bringing all standard quantifiers to the front:
\[
(\forall^* \Phi, \Xi, f)(\exists^* m^0)[[(\forall h^1, g^1) A(h, g, \Phi) \land (\forall Z^1) B(Z, \Xi(Z), \Phi)] \rightarrow C(f, m)], \tag{3.9}
\]
which is a normal form provable in \( \text{RCA}_0^3 \). Applying Corollary 2.5, there is a term \( t \) such that \( \text{RCA}_0^0 \) proves
\[
(\forall \Phi, \Xi, f)(\exists m^0 \in t(\Phi, \Xi, f))[[(\forall h^1, g^1) A(h, g, \Phi) \land (\forall Z^1) B(Z, \Xi(Z), \Phi)] \rightarrow C(f, m)],
\]
where \( \Phi \) is as in \( \text{UIP}_0^1 \) by \( (\forall h, g) A(h, g, \Phi) \) and \( \Xi \) is the associated extensionality functional by \( (\forall Z^1) B(Z, \Xi(Z), \Phi) \). Now define \( s(\Phi, \Xi, f) \) as the maximum of all \( t(\Phi, \Xi, f) \) for \( i < |t(\Phi, \Xi, f)| \) and note that \( (\forall f^1) C(f, s(\Phi, \Xi, f)) \) expresses that \( s(\Phi, \Xi, f) \) is Feferman’s non-constructive search operator. In other words, we have obtained the explicit implication \( \text{UIP}_0^1 \rightarrow (\mu^2) \), and we are done. \( \square \)

We immediately obtain the following ‘more explicit’ corollary, where \( \text{UIP}_0^1 \) is just \( \text{UIP}_0^0 \) with the leading existential quantifier omitted.

**Corollary 3.4.** From the proof of \( \text{UIP}_0^1 \leftrightarrow \Pi^1_0 \text{-TRANS} \) in \( \text{RCA}_0^3 \), two terms \( s, u \) can be extracted such that \( \text{RCA}_0^0 \) proves:
\[
(\forall \mu^2)[\mu(\mu) \rightarrow \text{UIP}_0^1 G(s(\mu)) \land (\forall \Phi)[\text{UIP}_0^1 G(\Phi) \rightarrow \mu(u(\Phi, \Xi))]], \tag{3.10}
\]
where \( \Xi \) is an extensionality functional for \( \Phi \).

**Proof.** The second conjunct is immediate from the theorem. The first conjunct can be obtained by establishing \( \Pi^1_0 \text{-TRANS} \rightarrow \text{UIP}_0^1 \) (which is almost trivial) in \( \text{RCA}_0^1 \) and applying Corollary 2.5 to this implication in normal form. \( \square \)

The proof of the theorem also provides a template as follows.

**Remark 3.5** (Algorithm B). Let \( T \equiv (\forall X^1)(\exists Y^1) \varphi(X, Y) \) be an internal formula and define the ‘strong’ uniform version \( UT^+ \) as
\[
(\exists^* \Phi^1 \rightarrow 1)[(\forall^* X^1) \varphi(X, \Phi(X)) \land \Phi \text{ is standard extensional}].
\]
The proof of Theorem 3.3 provides a normal form algorithm B to convert the implication \( UT^+ \rightarrow \Pi^1_0 \text{-TRANS} \) into a normal form \( (\forall^* x)(\exists^* y) \varphi(x, y) \) as in (3.9).

The previous theorem implies that we may extract an explicit equivalence from a nonstandard one. It is then a natural question (especially in the light of Reverse Mathematics) if we can also re-obtain the (proof of the) nonstandard equivalence from the (proof of the) explicit equivalence. This question will be answered in the positive in Section 4.2.
3.2. The finite intersection principle and 1-genericity. In this section, we study uniform versions of the finite intersection principle FIP from \[\text{[7]}\] and the principle 1-GEN related to Cohen forcing from \[\text{[5]}\]. By \[\text{[5]}\, \text{Theorem 5.8}\], the aforementioned principles are equivalent over RCA\(_0\).

First of all, to study 1-GEN in the higher-order framework, we define \(\sigma^0 \in S^X_f \equiv (\exists \tau^0) f(\sigma, \tau, X|\tau) = 0\) and let 1-GEN and its uniform version be as follows.

**Principle 3.6** (1-GEN).

\[
(\forall X^1)(\exists Y^1)(\forall f^1)[(\exists n^0)(\exists Y n \in S^X_f) \lor (\exists m^0)(\forall \sigma \geq Y n)(\sigma \notin S^X_f)].
\]

**Principle 3.7** (U1G). There is \(\Phi^{1 \rightarrow (1 \times 2 \times 2)}\) such that for all \(X^1, f^1\), we have

\[
(\Phi(X)(1) \Phi(X)(2)(f) \in S^X_f) \lor (\forall \sigma \geq \Phi(X)(1) \Phi(X)(3)(f))(\sigma \notin S^X_f). \tag{3.11}
\]

Note that the witnessing functional in the first disjunct is actually superfluous, as the base theory includes QF-AC\(^{1,0}\). We have the following theorem.

**Theorem 3.8.** In RCA\(_0^\omega\), we have U1G \(\iff (\mu^2)\), and this equivalence is explicit.

**Proof.** The reverse implication is immediate as ACA\(_0\) implies 1-GEN and \((\mu^2)\) easily (and explicitly) yields U1G in light of e.g. \[\text{[6]}\, 2.24.2\]. We now prove the remaining explicit implication using the template from Section 2.4. Thus, working in ACA\(_0^\omega\) + U1G\(^+\), suppose \(-\Pi^0\_\text{TRANS}\), i.e. there is a function \(h\) such that \((\forall n^0)h(n) = 0 \land (\exists m^0) h(m) \neq 0\). Let \(f_0\) and \(X_0\) be standard sequences such that the first conjunct of (3.11) is false, and define the standard function \(f_1\) as:

\[
f_1(\sigma, \tau, \rho) := \begin{cases} f_0(\sigma, \tau, \rho) & \text{otherwise} \\ 0 & (\exists n \leq |\sigma|)(h(n) \neq 0). \end{cases}
\]

With this definition, we observe that \(\sigma_1 := \Phi(X_0)(1) \Phi(X_0)(2)(f_1) =_0 \Phi(X_0)(1) \Phi(X_0)(2)(f_0) =: \sigma_0\), by standard extensionality, implying the following sequence of equivalences:

\[
[\sigma_1 \in S^X_{f_1}] \equiv [(\exists \tau^0) f_1(\sigma_1, \tau, X|\tau) = 0] \\
\equiv [(\exists \tau^0) f_0(\sigma_1, \tau, X|\tau) = 0] \equiv [(\exists \tau^0)(f_0(\sigma_0, \tau, X|\tau)) = 0] \equiv [\sigma_0 \in S^{X_0}_{f_0}],
\]

where the second step holds by the definition of \(f_1\) and the fact that \(\sigma_1\) is standard. In other words, the first conjunct of (3.11) is false for \(X_0, f_1\). Hence, the second conjunct of (3.11) must hold for \(X_0\) and for \(f_1\), i.e. we have

\[
(\forall \sigma \geq \Phi(X_0)(1) \Phi(X_0)(3)(f_1))(\forall \tau^0)(f_1(\sigma, \tau, X_0|\tau)) \neq 0.
\]

Since \(\Phi(X_0)(1) \Phi(X_0)(3)(f_1)\) is standard, we can apply the previous for \(\sigma = \Phi(X_0)(1)M\) for any nonstandard \(M\). However, this yields a contradiction as \(f_1\) is zero for long enough \(\sigma\). From this contradiction, we conclude that RCA\(_0^\omega\) proves U1G\(^+\) \(\rightarrow \Pi^0\_\text{TRANS}\). Analogous to the proof of Theorem 3.3, U1G\(^+\) \(\rightarrow \Pi^0\_\text{TRANS}\) may be brought into a normal form of the form (3.9), and applying Corollary 2.3 now finishes the proof.

Secondly, we briefly study the principle FIP in the following remark.
Remark 3.9. By [11] Prop. 2.3, ACA₀ is equivalent to a strengthened version of FIP where a set \( I \) is given such that \( i \in I \iff A_i \in \mathcal{B} \), where the latter is the maximal subfamily with the finite intersection property. It is straightforward to prove a uniform version (involving (\( \mu^2 \))) of this equivalence.

However, the uniform version of FIP will provide such a set \( I \) as in the strengthened version of FIP. In other words, the aforementioned results immediately imply that the uniform version of FIP is equivalent to (\( \mu^2 \)). Similarly, [7] Prop. 2.3 implies that the uniform versions of nIP (\( n \geq 2 \)) are all equivalent to (\( \mu^2 \)).

### 3.3. The omitting partial types principle

In this section, we study uniform versions of the Omitting Partial Types principle OPT which may be found in [11] §5 and [10] Def. 9.64.

In light of [11] Theorems 5.6-5.7 and particularly [10] 9.66-9.67, the uniform versions of OPT and HYP are (explicitly) equivalent. Hence, we study the latter, which is essentially the statement that for every set \( X \), there is a function which is not dominated by any \( X \)-computable function. In symbols, we have

\[
(\forall f^1)(\exists g^1)(\forall e^0, k^0)(\exists n^0 \geq k)(\forall m^0, s^0)[\varphi_{e,s}^f(n) = m \to m < g(n)],
\]

(HYP)

following the definition in [21] p. 189, 3.7]. Hence, the uniform version is

\[
(\exists \Phi^1 \to (1^1))(\forall e^0, k^0, m^0, s^0) [\Phi(f)(2)(e, k) \geq k \land \varphi_{e,s}^f(\Phi(f)(2)(e, k)) = m \to m < \Phi(f)(1)(\Phi(f)(2)(e, k))].
\]

(UHYP)

Theorem 3.10. In \( \text{RCA}_0^\dagger \), we have UHYP \( \leftrightarrow (\mu^2) \), and the equivalence is explicit.

**Proof.** The reverse implication is trivial as (\( \mu^2 \)) can check if a given Turing machine halts, and avoid the output if necessary. Working in \( \text{RCA}_0^\dagger + \text{UHYP}^+ \), suppose \( \neg \text{II}^1_1 \text{-TRANS} \), i.e. there is a function \( h \) such that \( (\forall^* n^0) h(n) = 0 \land (\exists m^0) h(m) \neq 0 \).

First of all, let the standard number \( e_0 \) be the code of the following program for \( \varphi_{e_0}^f \): On input \( n \), set \( k = n \) and check if \( f(k) > 0 \); If so, return this number; If \( f(k) = 0 \), repeat for \( k + 1 \). Intuitively speaking, \( e_0 \) is such that \( \varphi_{e_0}^f(n) \) outputs \( m > 0 \) if starting at \( k = n \), we eventually find \( m = f(k) > 0 \), and undefined otherwise. Furthermore, let \( f_0 \) be the sequence 00... and define

\[
f(e) := \begin{cases} 
\Phi(f_0)(1)(\Phi(f_0)(2)(e_0, e_0)) & (\exists s \leq e) h(s) \neq 0 \\
0 & \text{otherwise} 
\end{cases},
\]

where \( h \) is the exception to \( \text{II}^1_1 \text{-TRANS} \) from the first paragraph of this proof. Note that \( f \equiv_1 f_0 \) by definition, implying that \( \Phi \) satisfies \( \Phi(f) \equiv_{1^\dagger} \Phi(f_0) \) due to standard extensionality. However, the latter combined with UHYP gives us:

\[
\Phi(f_0)(1)(\Phi(f_0)(2)(e_0, e_0)) =_0 \Phi(f)(1)(\Phi(f)(2)(e_0, e_0)) \quad (3.12)
\]

\[
>_0 \varphi_{e_0, s_0}^f(\Phi(f)(2)(e_0, e_0)) =_0 \Phi(f_0)(1)(\Phi(f_0)(2)(e_0, e_0)),
\]

for large enough \( s_0 \) such that \( (\exists i \leq s_0) h(i) \neq 0 \). Note that it is essential for the first step in (3.12) that \( \Phi(f)(2)(e_0, e_0) \) and \( \Phi(f)(1)(\cdot) \) are standard. The contradiction in (3.12) implies that UHYP \( \rightarrow \text{II}^1_1 \text{-TRANS} \) in \( \text{RCA}_0^\dagger \). Now bring this implication in normal form and apply Corollary 2.5 to obtain the explicit implication. \( \square \)
In light of the proof of [10] 9.66, the uniform version of the atomic model theorem AMT is also (explicitly) equivalent to ($\mu^2$) by the previous theorem. Similarly, the proof of SADS $\rightarrow$ AMT in [11] Theorem 4.1 is sufficiently uniform to (explicitly) yield USADS $\rightarrow$ UAMT in RCA_0^\omega.

3.4. Non-computable sets. In this section, we study the uniform version of a principle ‘very close to RCA Non-computable sets.

3.4. Non-computable sets. In this section, we study the uniform version of a principle ‘very close to RCA Non-computable sets. The related principle is stated as follows:

$$
(\forall f^1)(\exists g^1)(\forall e^0)(\exists n^0)(\exists s^0)[g(n) \neq_0 \varphi_{e,s}^f(n)],
$$

which has the following uniform version:

$$(\exists \Phi^{1^\omega_r(1\times 1)})((\forall f^1)(\forall e^0,s^0)[\Phi(f)(1)(\Phi(f)(2)(e)) \neq_0 \varphi_{e,s}^f](\Phi(f)(2)(e))]].$$

Theorem 3.11. In RCA_0^\omega, we have UNCS $\leftrightarrow (\mu^2)$ and this equivalence is explicit.

Proof. The explicit implication ($\mu^2$) $\rightarrow$ UNCS is trivial as ($\mu^2$) supplies the Turing jump of any set. Working in RCA_0^\omega + UNCS^+, suppose $-\Pi^0_1$-TRANS, i.e. there is a function $h$ such that $(\forall^o n^0)h(n) = 0 \land (\exists^o m^0)h(m) \neq 0$.

First of all, fix a standard pairing function $\pi^1$ and its inverse $\xi^1$. Now let the standard number $e_{1}$ be the code of the following program: On input $n$, set $k = n$ and check if $k \in A$ and if $\xi(k)(2) > 0$; If so, return this non-zero component; If $k \notin A$ or $\xi(k)(2) = 0$, repeat for $k + 1$. Intuitively speaking, $e_{1}$ is such that $\varphi^{A}_{e_{1}}(n)$ outputs $m > 0$ if starting at $k = n$, we eventually find $\pi((l, m)) \in A$, and undefined otherwise. Furthermore, let $f_{0}$ be the sequence $00\ldots$ and define

$$f(e) := \begin{cases} 
\Phi(f_{0})(1)(\Phi(f_{0})(2)(e_{1})) & (\exists i \leq e)h(i) \neq 0 \\
0 & \text{otherwise}
\end{cases},$$

where $h$ is the exception to $\Pi^0_1$-TRANS from the first paragraph of this proof. Note that $f \equiv_{1} f_{0}$ by definition, implying that $\Phi$ satisfies $\Phi(f) \equiv_{1 \times 1} \Phi(f_{0})$ due to standard extensionality. However, the latter combined with UNCS gives us:

$$\Phi(f_{0})(1)(\Phi(f_{0})(2)(e_{1})) =_{0} \Phi(f)(1)(\Phi(f)(2)(e_{1})) \neq_{0} \varphi^{f}_{e_{1},s_{0}}(\Phi(f)(2)(e_{1}))$$

for large enough (infinite) $s_{0}$. Note that it is essential for the first step in 3.13 that $\Phi(f_{0})(2)(e_{1})$ and $\Phi(f)(1)(\cdot)$ are standard. The contradiction in 3.13 implies that RCA_0^\omega proves UNCS$^+$ $\rightarrow$ $\Pi^0_1$-TRANS. Now bring the latter in normal form and apply Corollary 2.5 to obtain the explicit implication.

Related to the above is the Kleene-Post theorem (See [12] and [21], Chapter VI) stating the existence of (Turing) incomparable sets. The related principle is:

$$(\forall f^1)(\exists g^1, h^1)[f \leq_T (g, h) \land g \upharpoonright_T h],$$

We denote by UKPT the fully uniform, i.e. with all existential quantifiers removed, version of KPT. Clearly, UKPT implies UNCS and the equivalence UKPT $\leftrightarrow (\mu^2)$ is now straightforward in light of [21] VI.1.1, p. 93.
4. Refining our results: meta-reversal and intuitionistic logic

In this section, we refine some of the results from [17] and the previous sections. First of all, we derive Theorem 3.3 using only systems based on intuitionistic logic in Section 4.1. The associated proof gives rise to a refinement of our template from Section 2.4. Secondly, we provide a ‘meta-reversal’ for Corollary 3.4 in Section 4.2 as follows: We show that a version of (3.11), called the Herbrandisation of $\text{UIP}_1^0 \rightarrow \Pi^0_1$-TRANS, implies the nonstandard implication $\text{UIP}_1^0 \rightarrow \Pi^0_1$-TRANS from which it was obtained. As we will see, these results generalise to all explicit equivalences proved above and in [17].

4.1. Non-classical equivalences. The explicit equivalences from the previous sections and [17] were established in $\text{RCA}_0^\lambda$ and $\text{RCA}_0^\omega$, i.e. systems based on classical logic. We show in this section that Corollary 3.4 essentially goes through for systems based on intuitionistic logic. As will become clear, the same technique applies to all theorems in this paper and [17].

This ‘constructive result’ is somewhat surprising, as our hitherto obtained results seem to make essential use of non-constructive principles: For instance, $\text{UIP}_1^0 \rightarrow \Pi^0_1$-TRANS was proved via a proof-by-contradiction, while obtaining the normal form of this implication involves the independence of premises principle to bring the standard quantifiers up front. Furthermore, basic results from computability theory, like Post’s complementation theorem ([21, Theorem 1.12]), already require non-constructive principles ([22, §4.5.3]), while our nonstandard technique will turn out to have a constructive counterpart.

The previous observations notwithstanding, let $H$ be the conservative extension of Heyting arithmetic introduced in [3, §5.2]. Note that $P$ from Section 2.2 is just $H$ with classical instead of intuitionistic logic. We consider two axioms of $H$, essential for the proof of Theorem 4.2 below.

**Definition 4.1.** [Two axioms of $H$]

1. **HIP**

   $$[(\forall x \phi(x) \rightarrow (\exists y \Psi(y))) \rightarrow (\exists y'((\forall x \phi(x) \rightarrow (\exists y \in y')\Psi(y)))],$$

   where $\Psi(y)$ is any formula and $\phi(x)$ is an internal formula of $E-HA^{\omega^*}$.

2. **HGMP**

   $$[(\forall x \phi(x) \rightarrow \psi) \rightarrow (\exists x'((\forall x \phi(x) \rightarrow \psi))],$$

   where $\phi(x)$ and $\psi$ are internal formulas in the language of $E-HA^{\omega^*}$.

Intuitively speaking, the two axioms of Definition 4.1 allow us to perform a number of non-constructive operations (namely Markov’s principle and independence of premises) on standard objects. In other words, the standard world of $H$ is ‘a little non-constructive’, but this does not affect the conservation result over Heyting arithmetic: $H$ and $E-HA^{\omega}$ prove the same internal formulas by [3, Cor. 5.6].

Surprisingly, we will observe that the axioms from Definition 4.1 are exactly what is needed for the proof of Corollary 3.4 to go through constructively. As in the proof of Theorem 3.3, we shall focus on the implication $\text{UIP}_1^0 \rightarrow \Pi^0_1$-TRANS, while the other implication is treated analogously. Note that $\text{UIP}_1^0(\Phi)$ is $\text{UIP}_1^0G$ with the leading quantifier omitted and $\text{MU}(\mu)$ is $(\forall f^1)\text{MUP}(f,\mu)$. 
Theorem 4.2. From the proof of $\text{UIP}_1^0 \mathcal{G}_1^+ \rightarrow \Pi^0_1\text{-TRANS}$ in $H$, a term $t$ can be extracted such that $E\text{-HA}^*\omega$ proves:

$$\forall \Phi \to \Phi\left[\text{UIP}_1^0 \mathcal{G}(\Phi) \rightarrow \text{MUP}(f, t(\Psi, \Phi, f))\right],$$

where $\Psi$ is an extensionality functional for $\Phi$.

Proof. To show that $H$ proves $\text{UIP}_1^0 \mathcal{G}_1^+ \rightarrow \Pi^0_1\text{-TRANS}$, it is straightforward to verify that the second part of the proof of Theorem 3.3 yields that

$$\text{UIP}_1^0 \mathcal{G}_1^+ \to \forall \Phi \exists f^1 \left[\exists n f(n) = 0 \to \neg \exists n f(n) \neq 0\right],$$

since $H$ is based on intuitionistic logic. However, by Definition 4.1, the system $H$ proves Markov’s principle relative to ‘st’, and hence:

$$\neg \exists n f(n) \neq 0 \to \exists n f(n) = 0.$$

Combining (4.2) and (4.3), we obtain $\text{UIP}_1^0 \mathcal{G}_1^+ \to \Pi^0_1\text{-TRANS}$ inside $H$. Now, the latter system also has a term extraction result, namely [3, Theorem 5.9], which is identical to Corollary 2.4. Hence, we only need to bring $\text{UIP}_1^0 \mathcal{G}_1^+ \to \Pi^0_1\text{-TRANS}$ into a normal form like (3.9) inside $H$, and (4.1) follows. We now bring $\text{UIP}_1^0 \mathcal{G}_1^+ \to \Pi^0_1\text{-TRANS}$ into a slight variation of the normal form (3.9) inside $H$.

First of all, applying the principle $\text{HIP}_{\forall \sigma}$ from Definition 4.1 to $\Pi^0_1\text{-TRANS}$, the latter implies (3.5), i.e. the former has a normal form, say (1.16) in Definition 4.1, and the latter now has exactly the right structure to apply $\text{HIP}_{\forall \sigma}$. Secondly, the second conjunct of $\text{UIP}_1^0 \mathcal{G}_1^+$ immediately implies (in $H$) that for all standard $f^1, g^1, u^1, v^1, k^0, i^0 \leq 1$, we have

$$(\forall^1 N^0) (\exists i^0) \left[\forall N =_0 N \wedge f N =_0 g N\right] \to \Phi(f, g)(i) =_0 \Phi(u, v)(i),$$

and applying $\text{HGMP}_{\forall \sigma}$ to (4.1), we obtain

$$(\exists^1 N^0) (\forall N =_0 N \wedge f N =_0 g N) \to \Phi(f, g)(i) =_0 \Phi(u, v)(i).$$

Define $Z^1$ as a code for the tuple of variables $f^1, g^1, u^1, v^1, k^0, i^0 \leq 1$ and let $B(Z, N^1, \Phi)$ be the formula in square brackets in the previous centred formula. Thus, the second conjunct of $\text{UIP}_1^0 \mathcal{G}_1^+$ has the normal form $\forall^1 Z^1 (\exists^1 M^0) B(Z, M, \Phi)$ and $\text{UIP}_1^0 \mathcal{G}_1^+ \to \Pi^0_1\text{-TRANS}$ implies:

$$(\forall^1 N^0) (\exists^1 \forall^0) \left[\forall^1 h^1, g^1, A(h, g, \Phi)(\exists^1 \exists^1 Z^2) (\forall^1 Z^1) B(Z, \Xi(Z), \Phi)\right] \to (\forall^1 f^1) (\exists^1 y^0) C(f, y),$$

where $A(\cdot)$ is (4.1) and the antecedent is strengthened by introducing $\Xi$. Inside $H$, we can bring outside the quantifiers involving the variables $\Psi, \Xi, f$, and $y$, yielding:

$$(\forall^1 \Xi, f) \left[\left(\forall^1 h^1, g^1, A(h, g, \Phi)(\forall^1 Z^1) B(Z, \Xi(Z), \Phi)\right) \to (\exists^1 y^0) C(f, y)\right],$$

which has exactly the right syntactic structure to apply $\text{HIP}_{\forall \sigma}$, and we obtain:

$$(\forall^1 \Xi, f)(\exists^1 \forall^0) \left[\left(\forall^1 h^1, g^1, A(h, g, \Phi)(\forall^1 Z^1) B(Z, \xi(Z), \Phi)\right) \to (\exists^1 y^0) C(f, y)\right],$$

and the latter now has exactly the right structure to apply $\text{HGMP}_{\forall \sigma}$, and we obtain:

$$(\forall^1 \Xi, f)(\exists^1 \forall^0, W^1),$$

$$\left[\left(\forall h^1, g^1 \in W A(h, g, \Phi)(\forall^1 Z^1) B(Z, \xi(Z), \Phi)\right) \to (\exists^1 y^0) C(f, y)\right],$$

which is a slight variation of the normal form (3.9), and the theorem follows by applying the term extraction result from [3] Cor. 5.9.

<sup>5</sup>Take $\psi \equiv [0 = 1]$ and $\phi$ a decidable formula in $\text{HGMP}_{\forall \sigma}$ in Definition 4.1.
Corollary 4.3. In E-HA^{ω}, \Pi_0^1G \leftrightarrow (\mu^2).

Note that we could have worked in a fragment of H similar to RCA^ω β. We finish this section with a remark stipulating the refinement using intuitionistic logic of the template in Section 2.4.

Remark 4.4. Based on the proof of Theorem 4.2, the template from Section 2.4 can be refined as follows to work for intuitionistic instead of classical logic.

1. Replace RCA^ω β and RCA^ω 0 by H and E-HA^{ω}.
2. In step (iv) of the template, we obtain that H ⊢ UT^+ → \Pi_1^0-TRANS from

   UT^+ → (\forall^st f^1)(\exists n) f(n) = 0 \rightarrow \neg[(\exists^st n) f(n) \neq 0],

   and HGMP^st as in (4.3) from the proof of Theorem 4.2.
3. In step (vi) of the template, use HGMP^st and HIF^st as in the proof of Theorem 4.2 to obtain a normal form of UT^+ → \Pi_1^0-TRANS.
4. In step (vi) of the template, apply the term extraction result formulated in Theorem 5.9 to the normal form of UT^+ → \Pi_1^0-TRANS.

Finally, it is surprising -in our opinion- that H includes exactly the right ‘non-constructive’ axioms -relative to ‘st’- as in Definition 4.1 to make the proof of Theorem 4.4 go through in a constructive setting.

4.2. Herbrandisations.

In this section, we provide a positive answer to the following natural RM-style question:

The algorithm \mathcal{RS} takes as input implications in Nonstandard Analysis and produces explicit implications related to the RM zoo. Is it possible to re-obtain these nonstandard ‘pre-cursor’ implications from their ‘post-cursor’ explicit implications?

To answer this question, we shall study the explicit implication \Pi_0^1G → (\mu^2) from Theorem 3.3, in particular a variation of the second conjunct of (3.10), defined as:

\[(\forall \Psi, \Xi, f^1)(\forall Z^1 \in i(\Psi, \Xi, f^1)1) B(Z, \Xi(Z), \Phi) \land (\forall f, g^1 \in i(\Phi, \Xi, f^1)2) A(f, g, \Phi)\]

\[\rightarrow ((\exists n) f(n) = 0 \rightarrow (\exists j \leq o(\Psi, \Xi, f) f(j) = 0))\] (HIO(i, o))

where A(\cdot) is (3.1) from \Pi_0^1G and B(\cdot) is (3.8) and expresses that \Xi is an extensionality functional for \Phi. We refer to HIO(i, o) as the Herbrandisation of \Pi_0^1G^+. Intuitively speaking, the functional i in the Herbrandisation tells us ‘how much’ \Phi has to satisfy \Pi_0^1G for a particular f^1 in order to obtain the value of the mu-operator at f via o (and the same for \Xi). In other words, the Herbrandisation is a ‘pointwise’ version of the second conjunct of (3.10).

We have the following theorem establishing a ‘meta-reversal’ between \Pi_0^1G^+ → \Pi_1^0-TRANS and its Herbrandisation HIO(i, o).

Theorem 4.5 (Meta-reversal). From the proof of \Pi_0^1G^+ → \Pi_1^0-TRANS in RCA^ω β, two terms i, o can be extracted such that RCA^ω β proves HIO(i, o). If there are terms i, o such that RCA^ω β proves HIO(i, o), then RCA^ω β proves \Pi_0^1G^+ → \Pi_1^0-TRANS.

Proof. Indeed, consider (3.9), but without the ‘st’ in the antecedent dropped, as follows:

\[(\forall^st \Phi, \Xi, f)(\exists^st m^0)\] \[\left[ (\forall^st h^1, g^1) A(f, g, \Phi) \land (\forall^st Z^1) B(Z, \Xi(Z), \Phi) \right] \rightarrow C(f, m)\].
Apply Corollary 2.5 to \( \text{RCA}_0 \) to obtain a term \( t \) such that \( \text{RCA}_0 \) proves

\[
(\forall \Phi, \Xi, f) (\exists m^0, h^1, g^1, Z^1) \left[ A(h, g, \Phi) \land B(Z, \Xi(Z), \Phi) \right] \rightarrow C(f, m),
\]

(4.6)

Define the term \( o \) as the maximum of all entries of \( t \) pertaining to \( m \); define \( i(\Psi, \Xi, f)(i) \) for \( i = 1 \) (resp. \( i = 2 \)) as all entries of \( t \) pertaining to \( h, g \) (resp. pertaining to \( Z \)). Then \( \text{HIO}(i, o) \) follows and this part is done.

For the second part of the theorem, suppose \( i, o \) are terms such that \( \text{RCA}_0^\omega \) proves \( \text{HIO}(i, o) \). By the second standardness axiom (See Definition 2.2), these terms are standard in \( \text{RCA}_0^\omega \), i.e. the latter proves \( \text{HIO}(i, o) \land \text{st}(i) \land \text{st}(o) \). Hence, for standard \( \Phi, \Xi, f \), the terms \( o(\Phi, \Xi, f) \) and \( i(\Phi, \Xi, f) \) are standard (by the third standardness axiom in Definition 2.2), and the consequent of \( \text{HIO}(i, o) \) clearly yields \( \Pi_0^1 - \text{TRANS} \), while the antecedent of the \( \text{HIO}(i, o) \) holds if \( \text{UII}^{\omega}_{1} G^+ \) does. Thus, we obtain that \( \text{RCA}_0^\omega \) proves \( \text{UII}^{\omega}_{1} G^+ \rightarrow \Pi_0^1 - \text{TRANS} \), and we are done.

Similar results hold for the first disjunct in (3.10). In general, one can obtain the Herbrandisation for any nonstandard equivalence from this paper and [17], and prove a result similar to the previous theorem. Intuitively speaking, the nonstandard implication \( \text{UII}^{\omega}_{1} G^+ \rightarrow \Pi_0^1 - \text{TRANS} \) and its Herbrandisation \( \text{HIO}(i, o) \) can be said to be ‘meta-equivalent’ or ‘share the same computational content’ in the sense of the theorem, namely that one can be obtained from the latter via an algorithmic manipulation.

Acknowledgement 4.6. This research was supported by the following funding bodies: FWO Flanders, the John Templeton Foundation, the Alexander von Humboldt Foundation, LMU Munich, and the Japan Society for the Promotion of Science. The author expresses his gratitude towards these institutions. The anonymous referee of this paper has offered a number of suggestions which greatly improved this paper.
