Abstract In this paper, using the Bestest Little Higgs Model (BLHM) we calculate at the one-loop level the contributions to the Anomalous Magnetic Dipole Moment (AMDM) and Anomalous Weak Magnetic Dipole Moment (AWMDM) of the tau-lepton. The implications from this model are studied, emphasizing the contributions of the new physics induced by the new scalar and vector bosons of the BLHM: \( S_1 = H_0, A_0, \phi^0, \eta^0, \sigma, H^\pm, \phi^\pm, \eta^\pm, \) and \( V_i = Z', W^\pm \) because these quantify the new physics. With these new contributions, we estimated bounds on the real and imaginary parts of the AMDM and AWMDM of the tau-lepton. Our study complements other one-loop-level research performed on models beyond the Standard Model.

1 Introduction

The study of the physics of the tau-lepton by the ATLAS and CMS experiments [1–5] at the Large Hadron Collider (LHC) has developed significantly and now represents a very active physics program. In addition, the following present and future colliders: hadron–hadron (\( pp \)), lepton–hadron (\( e^- p \)), and lepton–lepton (\( e^+ e^-, \mu^+ \mu^- \)) for the post LHC era will open up new horizons in the field of fundamental physics. All of these colliders contemplate in their physics programs the study of the physics of the tau-lepton.

In the Standard Model (SM) of elementary particle physics, as well as in many of its extensions, the search for Anomalous Magnetic Dipole Moments (AMDM), Electric Dipole Moments (EDM), and Anomalous Weak Magnetic Dipole Moments (AWMDM) of fundamental fermions, and in particular from the tau-lepton is an essential aspect of theoretical, phenomenological and experimental investigations hunting for physics beyond the Standard Model (BSM) of particle physics. For a review of the bounds on the electromagnetic and weak dipole moments, see Refs. [6–20].

In the lepton sector, the tau-lepton is a key particle in the SM and several extensions of the SM as it is considered a laboratory for many experimental or simulation aspects of the search for new physics. This particle is characterized by its high mass [21] compared to the mass of the electron or muon, so one would expect its electromagnetic and weak dipole moments to be much more sensitive to the effects of new physics than the electron or muon itself [19]. Unfortunately, the very short \( \tau \) lifetime [21] makes it very difficult to measure its dipole moments (AMDM, EDM, AWMDM) with a precision good enough to perform a significative test. The spin-precession technique adopted in the electron and muon \( g - 2 \) is no-longer feasible [19]. Instead, one measures the production of tau pairs at different high-energy processes. For instance, the most stringent current bound on the \( \tau \) EDM (see Table 1) was derived using the data collected by the DELPHI Collaboration from measurements in the cross-section of the process \( e^+ e^- \rightarrow e^+ e^- \tau^+ \tau^- \) at \( \sqrt{s} \) between 183 and \( 208 \) GeV at LEP2 [22]. As for the \( \tau \) AMDM, \( d_\tau \), the BELLE Collaboration searched for CP-violation effects in the \( e^+ e^- \rightarrow \gamma^* \rightarrow \tau^+ \tau^- \) process using triple momentum and spin correlations [23]. Through this reaction, they obtained the limits shown in Table 1 for the real and imaginary parts of the \( \tau \) EDM. In the SM scenario, the theoretical predictions on the \( \tau \) AMDM and EDM are: \( a_\tau^{SM} = 117721(5) \times 10^{-8} \) [24–26] and \( d_\tau^{SM} < 10^{-34} \) ecm [27–29], respectively. These results are well below current experimental limits.

Another intrinsic property of the \( \tau \)-lepton that has received attention in recent years due to important advances in the experimental domain consists of the weak dipole moments...
of the tau, which are associated with its interaction with the \( Z \) gauge boson. Both the AWMDM and the Weak Electric Dipole Moment (WEDM) of the \( \tau \)-lepton, \( a_\tau^W \) and \( d_\tau^W \), have been investigated with LEP data [30–32]. In Table 2 we show the current best experimental bounds on \( a_\tau^W \) and \( d_\tau^W \). These limits are obtained through \( e^+e^- \) production at LEP by the ALEPH Collaboration, corresponding to an integrated luminosity of 155 pb\(^{-1}\) [30]. On the theoretical side, the reached precisions in the AWMDM and WEDM of the tau-lepton are

\[
\begin{align*}
&\text{AWMDM}_\tau - \langle 0.20 \pm 0.61 \rangle \times 10^{-6} [33] \\
&\text{WEDM}_\tau < 8 \times 10^{-34} \text{ ecm} [34].
\end{align*}
\]

These values are well below the current experimental sensitivity. This opens the possibility of looking for deviations from the SM; therefore, studying extensions of the SM could generate significant contributions of new physics that are closer to the experimental bounds. With these motivations, we research on the electromagnetic and weak dipole moments of the tau-lepton in the context of the BLHM.

Based on everything already mentioned above, in this paper, we estimate the sensitivity bounds on the AMDM and AWMDM of the \( \tau \)-lepton in the SM and BLHM scenario, and emphasis will be placed on the contributions generated by the particles predicted by the BLHM, as these quantify the new physics.

The purpose of the BLHM is to solve the hierarchy problem without fine-tuning. This is achieved through the incorporation of one-loop corrections to the Higgs boson mass through heavy top-quark partners and heavy gauge bosons. This extension of the SM predicts the existence of new physical scalar bosons neutral and charged \( H_0, A_0, \phi^0, \eta^0, \sigma, H^\pm, \phi^\pm, \eta^\pm \), new heavy gauge bosons \( Z', W'^\pm \) and new heavy quarks \( B, T, T_3, T_6, T_{2/3}, T_{5/3} \). At the one-loop level, the AMDM \( a_\tau \) and AWMDM \( a_\tau^W \) of the \( \tau \)-lepton are induced via the Feynman diagrams represented in Figs. 1 and 2, where \( S_i, \Phi_i^\pm \) and \( H_i \) represent scalar bosons, \( V_i \) and \( W_i^\pm \) gauge bosons, and \( l_i \) leptons. In the framework of the BLHM, new model contributions are those arising from the vertices of scalars bosons, vector bosons and vector-scalar bosons, that is to say, vertices of the form (see Figs. 1 and 2):

\[
\begin{align*}
&\gamma W^+ W^-, \ Z W^+ W^-, \ Y W^+ \Phi_i^\pm, \ W_i^\pm = W^\pm, W'^\pm, \Phi_i^\pm = \phi^\pm, \eta^\pm, \ Z W_i^\pm \phi_i^\pm, \ Z Z H_0, \ Z Z' H_1, \ H_i = h_0, H_0, \ H_0^0, \ \tau \ l_i S_i, S_i = H_0, A_0, \phi^0, \eta^0, \sigma, H^\pm, \phi^\pm, \eta^\pm; \ \tau l_i V_i, \ V_i = Z', W'^\pm; \ \gamma l_i l_i, \ \text{and} \ Z l_i l_i, \ \text{where} \ l_i = \tau, \nu_i. \ \text{With these vertices, we calculate the one-loop contributions to the AMDM and AWMDM of the} \ \tau \text{-lepton and in several scenarios with} m_A^0 = 1000 \text{ GeV}, m_{\phi^0} = 100 \text{ GeV}, \tan \beta = 3, \\
f = [1000, 3000] \text{ GeV and} \ F = [3000, 6000] \text{ GeV}. \ \text{The paper is structured as follows. In Sect. 2, we give a brief review of the BLHM. In Sect. 3, we present the predictions of the BLHM on the electromagnetic and weak dipole moments of the \( \tau \)-lepton. In Sect. 4, we discuss the sensitivity bounds obtained on the AMDM and AWMDM of the \( \tau \)-lepton. Finally, we present our conclusions in Sect. 5. In Appendix A, we present the Feynman rules employed in the study of electromagnetic and weak dipole moments of the \( \tau \)-lepton in the context of the BLHM. In Appendix B, we provide the one-loop level SM predictions on the AMDM and AWMDM of the \( \tau \)-lepton.}

### 2 The bestest Little Higgs model

Various extensions of the SM, such as Little Higgs Models (LHM) [35,36], have been proposed to solve the problem of the mass hierarchy. This class of models employs a complex mechanism named collective symmetry breaking. The main idea is to represent the SM Higgs boson as a pseudo-Nambu-Goldstone boson of an approximate global symmetry that is spontaneously broken at a scale in the TeV range. In these models, the collective symmetry breaking mechanisms is implemented in the norm sector, fermion sector, and the Higgs sector, which predicts new particles within the mass range of a few TeV. These new particles play the role of partners of the top-quark, of the gauge bosons, and the Higgs boson, the effect of which is to generate radiative corrections for the mass of the Higgs boson and thus cancel the divergent corrections induced by SM particles. However, LHM [35–37] are already strongly constrained by electroweak precision data. These constraints typically require the new gauge bosons of LHM to be quite heavy [38,39]. In most LHM, the top partners are heavier than the new gauge bosons, which can lead to significant fine-tuning in the Higgs potential [40].

An exciting and relatively recent model is the BLHM [41] which overcomes these difficulties by including separate symmetry breaking scales at which the heavy gauge boson and top partners obtain their masses. This model generates heavy gauge boson partner masses above the excluded mass range and has light top partners below the upper bound from fine-tuning. The BLHM is based on two independent non-linear sigma models. With the first field \( \Sigma \), the global symmetry
$SO(6)_A \times SO(6)_B$ is broken to the diagonal group $SO(6)_V$ at the energy scale $f$, while with the second field $\Delta$, the global symmetry $SU(2)_C \times SU(2)_D$ to the diagonal subgroup $SU(2)$ to the scale $F > f$. In the first stage are generated 15 pseudo-Nambu-Goldstone bosons that are parameterized as

$$\Sigma = e^{i\Pi/f} e^{i\Pi_\Delta/f} e^{i\Pi_\Delta/f},$$  
(1)

where $\Pi$ and $\Pi_\Delta$ are complex and antisymmetric matrices given in Ref. [41]. Regarding the second stage of spontaneous symmetry-breaking, the pseudo-Nambu-Goldstone bosons of the field $\Delta$ are parameterized as follows

$$\Delta = Fe^{i\Pi_d/F}, \quad \Pi_d = \chi_a \frac{r_a}{2} (a = 1, 2, 3),$$  
(2)

$\chi_a$ represents the Nambu-Goldstone fields and the $r_a$ correspond to the Pauli matrices [41], which are the generators of the $SU(2)$ group.

2.1 The scalar sector

The BLHM Higgs fields, $h_1$ and $h_2$, form the Higgs potential that undergoes spontaneous symmetry breaking [41–43]:

$$V_{Higgs} = \frac{1}{2} m_1^2 h_1^2 + \frac{1}{2} m_2^2 h_2^2 - B_\mu h_1^2 h_2 - \frac{\lambda_0}{2} (h_1^2 h_2)^2.$$  
(3)

The potential reaches a minimum when $m_1, m_2 > 0$, while to break the electroweak symmetry requires $B_\mu > m_1 m_2$. The symmetry-breaking mechanism is implemented in the BLHM when the Higgs doublets acquire their vacuum expectation values (VEVs), $\langle h_1 \rangle^T = (v_1, 0, 0, 0)$ and $\langle h_2 \rangle^T = (v_2, 0, 0, 0)$. By demanding that these VEVs minimize the Higgs potential of Eq. (3), the following relations are obtained

$$v_1^2 = \frac{1}{\lambda_0} \frac{m_2}{m_1} (B_\mu - m_1 m_2),$$  
(4)

$$v_2^2 = \frac{1}{\lambda_0} \frac{m_1}{m_2} (B_\mu - m_1 m_2).$$  
(5)

These parameters can be expressed as follows

$$v^2 \equiv v_1^2 + v_2^2 = \frac{1}{\lambda_0} \left( \frac{m_1^2 + m_2^2}{m_1 m_2} \right) (B_\mu - m_1 m_2)$$  
$$\simeq (246 \text{ GeV})^2,$$  
(6)

$$\tan \beta = \frac{v_1}{v_2} = \frac{m_2}{m_1}.$$  
(7)

From the diagonalization of the mass matrix for the scalar sector, three non-physical fields $G_0$ and $G^\pm$, two physical scalar fields $H^\pm$ and three neutral physical scalar fields $h_0$, $H_0$ and $A_0$ are generated [42,44]. The lightest state, $h_0$, is identified as the scalar boson of the SM. The masses of these fields are given as

$$m_{G_0} = m_{G^\pm} = 0,$$  
(8)

$$m_{A_0}^2 = m_{H_0}^2 = m_1^2 + m_2^2,$$  
(9)

$$m_{H_0}^2 = \frac{B_\mu}{\sin 2 \beta} + \frac{B_\mu^2}{\sin^2 2 \beta} - 2 \lambda_0 B_\mu v^2 \sin 2 \beta + \lambda_0^2 v^4 \sin^2 2 \beta.$$  
(10)

The four parameters present in the Higgs potential $m_1, m_2, B_\mu$ and $\lambda_0$ can be replaced by another more phenomenologically accessible set. That is, the masses of the states $h_0$ and $A_0$, the angle $\beta$ and the VEV $v$ [42]:

$$B_\mu = \frac{1}{2} \left( \lambda_0 v^2 + m_2^2 \right) \sin 2 \beta,$$  
(11)

$$\lambda_0 = \frac{m_2^2}{v^2} \left( \frac{m_2^2 - m_0^2}{m_2^2 - m_0^2 \sin^2 2 \beta} \right),$$  
(12)

$$\tan \alpha = \frac{B_\mu \cot 2 \beta + \sqrt{(B_\mu^2/\sin^2 2 \beta) - 2 \lambda_0 B_\mu v^2 \sin 2 \beta + \lambda_0^2 v^4 \sin^2 2 \beta}}{B_\mu - \lambda_0 v^2 \sin 2 \beta},$$  
(13)

$$m_{H_0}^2 = \frac{B_\mu}{\sin 2 \beta} \sqrt{\frac{B_\mu^2}{\sin^2 2 \beta} - 2 \lambda_0 B_\mu v^2 \sin 2 \beta + \lambda_0^2 v^4 \sin^2 2 \beta},$$  
(14)

$$m_0^2 = \langle \lambda_{56} + \lambda_{65} \rangle f^2 = 2 \lambda_0 f^2 K_\sigma.$$  
(15)

The variables $\lambda_{56}$ and $\lambda_{65}$ in Eq. (15) represent the coefficients of the quartic potential defined in [41], both variables take values different from zero to achieve the collective breaking of the symmetry and generate a quartic coupling of the Higgs boson [41,42]. The BLHM also contains scalar triplet fields that get a contribution to their mass from the explicit symmetry breaking terms in the model, as defined in Ref. [41], that depends on the parameter $m_4$.

$$m_{\phi_0}^2 = \frac{16}{3} F^2 \frac{3 \bar{g}^2 A^2 B^2}{32 \pi^2} \log \left( \frac{\Lambda^2}{m_{W^+}^2} \right).$$
SU\(L\) are given as follows:

\[
m_{\phi}^2 = \frac{16 F^2 3 g^2_{\text{A}} g^2_{\text{B}}}{52\pi^2} \log \left( \frac{\Lambda^2}{m^2_{W^\pm}} \right),
\]

\[
m_{\gamma}^2 = \frac{4 F^2 f^4 + F^4}{F^2(f^2 + F^2)},
\]

\[
m_{\eta^+}^2 = \frac{m^2_{\phi} + 3 f^2 g^2_{\text{Y}} \Lambda^2}{64\pi^2 F^2},
\]

\[
m_{\eta^0}^2 = m_{\eta^+}^2.
\]

2.2 The gauge sector

In the BLHM, the new gauge bosons develop masses proportional to \(\sqrt{f^2 + F^2} \sim F\). This makes the masses of the gauge bosons large relative to other particles that have masses proportional to \(f\). The kinetic terms of the gauge fields in the BLHM are given as follows:

\[
\mathcal{L} = \frac{f^2}{8} \text{Tr}(D_\mu \Sigma^\dagger D^\mu \Sigma) + \frac{F^2}{4} \text{Tr}(D_\mu \Delta^\dagger D^\mu \Delta),
\]

where

\[
D_\mu \Sigma = \partial_\mu \Sigma + ig_A A^a_{1\mu} T^a L \Sigma
\]

\[
-ig_B A^2_{2\mu} T^a L + ig_Y B^3_\mu (T^3_\Sigma - \Sigma T^3),
\]

\[
D_\mu \Delta = \partial_\mu \Delta + ig_A A^a_{1\mu} \tau^a \Delta - ig_B A^3_{2\mu} \tau^a \Delta.\]

\(T^a_L\) are the generators of the group \(SO(6)_A\) corresponding to the subgroup \(SU(2)_{1A}\), while \(T^3_\Sigma\) represents the third component of the \(SO(6)_{1B}\) generators corresponding to the \(SU(2)_{1B}\) subgroup. These matrices are provided in [41]. \(g_A\) and \(A^a_{1\mu}\) denote the gauge coupling and field associated with the gauge bosons of \(SU(2)_{1A}\); \(g_B\) and \(A^3_{2\mu}\) represent the gauge coupling and the field associated with \(SU(2)_{1B}\); while \(g_Y\) and \(B^3_\mu\) denote the hypercharge and the field. When \(\Sigma\) and \(\Delta\) get their VEVs, the gauge fields \(A^a_{1\mu}\) and \(A^3_{2\mu}\) are mixed to form a massless triplet \(A^a_{1\mu}\) and a massive triplet \(A^3_{H\mu}\),

\[
A^a_{1\mu} = \cos \theta_g A^a_{1\mu} + \sin \theta_g A^3_{2\mu},
\]

\[
A^3_{H\mu} = \sin \theta_g A^a_{1\mu} - \cos \theta_g A^3_{2\mu},\]

with the mixing angles

\[
s_g \equiv \sin \theta_g = \frac{g_A}{\sqrt{g^2_A + g^2_B}}, \quad c_g \equiv \cos \theta_g = \frac{g_B}{\sqrt{g^2_A + g^2_B}},
\]

which are related to the electroweak gauge coupling \(g\) through

\[
\frac{1}{g^2} = \frac{1}{g^2_A} + \frac{1}{g^2_B}.\]

After breaking the electroweak symmetry, when the Higgs doublets, \(h_1\) and \(h_2\) acquire their VEVs, the masses of the gauge bosons of the BLHM are generated. In terms of the model parameters, the masses are given by

\[
m_{\gamma}^2 = 0,
\]

\[
m_{Z}^2 = \frac{1}{4} (g^2 + g_Y^2) v^2 \times \left( 1 - \frac{v^2}{12 f^2} (2 + \frac{3 f^2}{f^2 + F^2} (g^2 - c^2_g)^2) \right),
\]

\[
m_{W^\pm}^2 = \frac{1}{4} g^2 v^2 \left( 1 - \frac{v^2}{12 f^2} (2 + \frac{3 f^2}{f^2 + F^2} (c^2_g - c^2_s)^2) \right),
\]

\[
m_{W^0}^2 = \frac{g^2 v^4}{16 c^2_\gamma g^2} (f^2 + F^2) - m_{W^\pm}^2.
\]

The weak mixing angle is defined as

\[
s_W \equiv \sin \theta_W = \frac{g_Y}{\sqrt{g^2 + g_Y^2}},
\]

\[
c_W \equiv \cos \theta_W = \frac{g}{\sqrt{g^2 + g_Y^2}},
\]

2.3 The Yang–Mills sector

The gauge boson self-interactions arise from the following Lagrangian terms:

\[
\mathcal{L} = F_{1\mu
\nu} F_{1\mu
\nu} + F_{2\mu
\nu} F_{2\mu
\nu},
\]

where \(F_{1\mu
\nu}\) and \(F_{2\mu
\nu}\) are given by:

\[
F_{1\mu
\nu} = \partial_\mu A^{aq}_{1\nu} - \partial_\nu A^{aq}_{1\mu} + g_A \sum_b c_{\mu \nu} c_{ab} A^{b\mu}_{1\nu} A^{c\nu}_{1\mu},
\]

\[
F_{2\mu
\nu} = \partial_\mu A^{aq}_{2\nu} - \partial_\nu A^{aq}_{2\mu} + g_B \sum_b c_{\mu \nu} c_{ab} A^{b\mu}_{2\nu} A^{c\nu}_{2\mu}.
\]

In these equations, the indices \(a, b\) and \(c\) run over the three gauge fields [45]; \(c_{abc}\) is the anti-symmetric tensor.

2.4 The fermion sector

To construct the Yukawa interactions in the BLHM, the fermions must be transformed under the group \(SO(6)_A\) or \(SO(6)_B\). In this model, the fermion sector is divided into two parts. First, the sector of massive fermions is represented by Eq. (36). This sector includes the top and bottom quarks of the SM and a series of new heavy quarks arranged in four multiplets, \(Q\) and \(Q'\) which transform under \(SO(6)_A\), while
$U^c$ and $U_5^c$ are transformed under the group $SO(6)_R$. Second, the sector of light fermions contained in Eq. (37), in this expression, all the interactions of the remaining fermions of the SM with the exotic particles of the BLHM are generated.

For massive fermions, the Lagrangian that describes them is given by [41]

$$L_m = y_u f q_i^c S U^c + y_d f q_i^c T S U^c + y_3 f Q^c S U_5^c$$

$$+ y_b f q_i^c (-2i T_R^2 \Sigma) U_b^c + h.c.,$$

where $S = \text{diag}(1, 1, 1, 1, -1, -1)$. The explicit representation of the multiplets involved in Eq. (36) is provided in Refs. [41,44]. For simplicity, the Yukawa couplings are assumed to be real $y_1, y_2, y_3 \in \mathbb{R}$.

For light fermions the corresponding Lagrangian is [41,44,45]

$$L_{\text{light}} = \sum_{i=1,2} y_3 f q_i^c \Sigma u_i^c + \sum_{i=1,2} y_d f q_i^c (-2i T_R^2 \Sigma) d_i^c$$

$$+ \sum_{i=1,2,3} y_e f l_i^c (-2i T_R^2 \Sigma) e_i^c + h.c.$$

2.5 The currents sector

The Lagrangian that describes the interactions of fermions with the gauge bosons is [41,44]

$$\mathcal{L} = \tilde{Q} \tau^\mu D_\mu Q + \tilde{U} \tau^\mu D_\mu U + U^c \tau^\mu D_\mu U^c$$

$$- U^c \tau^\mu D_\mu U^c - U_5^c \tau^\mu D_\mu U_5^c + \sum_{i=1,2} q_i^c \tau^\mu D_\mu q_i$$

$$+ \sum_{i=1,2,3} l_i^c \tau^\mu D_\mu l_i - \sum_{i=1,2,3} e_i^c \tau^\mu D_\mu e_i$$

$$- \sum_{i=1,2} u_i^c \tau^\mu D_\mu u_i - \sum_{i=1,2} d_i^c \tau^\mu D_\mu d_i,$$

where $\tau^\mu$ and $\tilde{\tau}^\mu$ are defined according to [46]. On the other hand, the respective covariant derivatives are provided in Refs. [44,45].

3 Electromagnetic and weak dipole moments of the tau-lepton in the BLHM

The electromagnetic properties of fermions are characterized by physical magnitudes called form factors. These measure properties such as the electric charge, the AMDM, the EDM, the AWMDM, the WEDM, and others. Some of these quantities are already present in classical theory, while others arise for the first time as a quantum fluctuation of one-loop or higher orders. In quantum field theory, the electromagnetic and weak properties of fermions arise through their interaction with the gauge boson $V$, $V = \gamma, Z$. The most general Lorentz-invariant vertex function describing the interaction of a gauge boson with two fermions can be written in terms of ten form factors [47,48], which are functions of the kinematic invariants. In the low energy limit, these correspond to couplings that multiply dimension-four or-five operators in an effective Lagrangian and may be complex. If the gauge boson $V$ is on-shell, or if $V$ couples to effectively massless fermions, the number of independent form factors is reduced to eight. In addition, if the fermions are on-shell, the number is further reduced to four. In this way, the $V \tilde{f} f$ vertex function can be written in the form

$$ie\bar{u}(p')\sigma_{\mu\nu}f(p)u(p) = ie\bar{u}(p') \gamma^\mu \left[ F_V^V(q^2) - F_A^V(q^2)\gamma^5 \right]$$

$$+ ie\bar{u}(p') \left[ F_Y^V(q^2) - iF_E^V(q^2)\gamma^5 \right]u(p),$$

where $e$ is the proton charge and $q = p' - p$ the $V$ gauge boson transferred four-momentum. The terms $F_V^V(0)$ and $F_A^V(0)$ in the low energy limit are the $V \tilde{f} f$ vector and axial-vector form factors in the SM, while $F_Y^V(q^2)$ and $F_E^V(q^2)$ are associated with the form factors of the electromagnetic or weak dipole moments. The latter arise at the loop level and are a valuable tool to study the effects of new physics indirectly, through virtual corrections of new particles predicted by extensions of the SM. The AWMDM and WEDM are given by $a_Y^W = -2m_f F_M^W(q^2 = m_Z^2)$ and $a_Y^W = -eF_E^W(q^2 = m_Z^2)$, whereas the electromagnetic properties, $a_Y^V$ and $d_f$, are defined by analogue expressions but with the replacement $q^2 = 0$.

3.1 The AMDM and AWMDM of the tau-lepton at the BLHM

In this subsection, we are interested in the contributions generated by the new BLHM particles to the electromagnetic and weak dipole moments of the tau-lepton. At the one-loop level, the $\tau$ EDM and WEDM are absent, so they do not receive contributions of the radiative corrections. However, the $\tau$ AMDM and AWMDM are induced by scalar bosons, vector bosons and, leptons via the Feynman diagrams depicted in Figs. 1 and 2. In these figures, $S_i$ and $\Phi_i^\pm$ represent the new scalars $A_0, H_0, H^\pm, \eta^0, \phi^0, \sigma, \eta^\pm, \phi^\pm$; $V_i$ stands for the new gauge bosons $Z', W^\pm$, and $W^\pm$ the gauge bosons $W^\pm, W^\pm$; and finally, $l_i$ denotes the leptons $\tau, \nu_\tau$. To obtain the amplitude of each contribution, we use the Feynman rules provided in Appendix A [49]. We used the unitary gauge for our calculations and implemented the Passarino–Veltman reduction scheme to solve the loop integrals involved in the amplitudes. Such amplitudes are also gauge independent since the $V$ gauge boson is on-shell, as well as the tau-lepton pair. It is worth mentioning that the contributions for the AMDM and AWMDM of the $\tau$-lepton are free of divergences.
sified in terms of the six classes of triangle diagrams. Each category can be written in the following compact notation

\[ \mathcal{M}_n(S_{i,l_1}; l_i) = C_{n,l_1}^i \int \frac{d^4k}{(2\pi)^4} \bar{u}(p_2) \left[ \frac{k^+ + p_2 + m_i}{(k + p_2)^2 - m_i^2} \right] u(p_1) \left( \gamma^\mu (F_{\mu} + F_{\mu} \gamma^5) \right) \]

\[ \times \left( \gamma^\nu (F_{\nu} + F_{\nu} \gamma^5) \right) \left( \frac{k^+ + p_1 + m_i}{(k + p_1)^2 - m_i^2} \right) \left( \frac{i}{k^2 - m_i^2} \right). \]  

(40)

\[ \mathcal{M}_n^V(V_{i,l_1}; l_i) = \int \frac{d^4k}{(2\pi)^4} \bar{u}(p_2) \left[ \frac{k^+ + p_2 + m_i}{(k + p_2)^2 - m_i^2} \right] u(p_1) \left( \gamma^\mu (F_{\mu} + F_{\mu} \gamma^5) \right) \]

\[ \times \left( \gamma^\nu (F_{\nu} + F_{\nu} \gamma^5) \right) \left( \frac{k^+ + p_1 + m_i}{(k + p_1)^2 - m_i^2} \right) \left( \frac{i}{k^2 - m_i^2} \right) \left( C_{i,l_1}^{\gamma_\alpha \gamma_\beta} \gamma_\alpha P_{\alpha} \gamma_\beta P_{\beta} \right) \]

\[ \times \left( \gamma^\mu (F_{\mu} + F_{\mu} \gamma^5) \right) \left( \frac{i}{k^2 - m_i^2} \right). \]  

(41)

\[ \mathcal{M}_n^\phi(W^++l_1;l_i) = \int \frac{d^4k}{(2\pi)^4} \bar{u}(p_2) \left[ C_{i,l_1}^{\gamma_\alpha \gamma_\beta} \gamma_\alpha P_{\alpha} \gamma_\beta P_{\beta} \right] \]

\[ \times \left( \gamma^\mu (F_{\mu} + F_{\mu} \gamma^5) \right) \left( \frac{i}{k^2 - m_i^2} \right) \left( \gamma^\nu (F_{\nu} + F_{\nu} \gamma^5) \right) \left( \frac{i}{k^2 - m_i^2} \right). \]

(42)

\[ \mathcal{M}_n^\phi(W^-\Phi^+l_1) = \int \frac{d^4k}{(2\pi)^4} \bar{u}(p_2) \left[ C_{i,l_1}^{\gamma_\alpha \gamma_\beta} \gamma_\alpha P_{\alpha} \gamma_\beta P_{\beta} \right] \]

\[ \times \left( \gamma^\mu (F_{\mu} + F_{\mu} \gamma^5) \right) \left( \frac{i}{k^2 - m_i^2} \right) \left( \gamma^\nu (F_{\nu} + F_{\nu} \gamma^5) \right) \left( \frac{i}{k^2 - m_i^2} \right) \left( \gamma^\nu (F_{\nu} + F_{\nu} \gamma^5) \right) \left( \frac{i}{k^2 - m_i^2} \right). \]

(43)

\[ \mathcal{M}_n^\phi(W^+W^-l_1;l_i) = \int \frac{d^4k}{(2\pi)^4} \bar{u}(p_2) \left[ C_{i,l_1}^{\gamma_\alpha \gamma_\beta} \gamma_\alpha P_{\alpha} \gamma_\beta P_{\beta} \right] \]

\[ \times \left( \gamma^\mu (F_{\mu} + F_{\mu} \gamma^5) \right) \left( \frac{i}{k^2 - m_i^2} \right) \left( \gamma^\nu (F_{\nu} + F_{\nu} \gamma^5) \right) \left( \frac{i}{k^2 - m_i^2} \right) \left( \gamma^\nu (F_{\nu} + F_{\nu} \gamma^5) \right) \left( \frac{i}{k^2 - m_i^2} \right). \]

a Scalar contributions, $S_i \equiv A_0, H_0, H^\pm, \eta^\pm, \phi^\pm, \sigma, \eta^\pm, \phi^\pm, \eta^\pm$.

b, c Vector contributions, $V_i \equiv Z', W'^\pm, \Phi'^\pm$.

d-g Scalar–vector contributions, $W_i'^\pm = W'^\pm, \Phi_i'^\pm = \phi'^\pm, \eta'^\pm$.

and $H_i = h_0, H_0$
where \( F_V \) and \( F_A \) denote the form factors of the vector and axial-vector. On the other hand, \( Z = Z' \), while \( C \) (or \( C^* \)) denotes the coupling constants of the corresponding vertices. The tensor \( \mathcal{A}_{VW}^{BLHM} \) is provided in Table 9 of Appendix A. From these amplitudes, we obtain the new physics contributions induced by the scalar and vector bosons, particles of the BLHM. The effects of the new physics are determined in the following way

\[
\begin{align*}
\alpha_t &= \alpha_t^{BLHM} = [\alpha_t^S + \alpha_t^V] + [\alpha_t^S - \alpha_t^V], \\
\alpha_t^W &= \alpha_t^{W-BLHM} = [\alpha_t^W] + [\alpha_t^W - \alpha_t^V] \quad \text{(46)}
\end{align*}
\]

We also consider the total contributions, that is, which result from the sum of the contributions of the SM (see Appendix B) and BLHM.

\[
\begin{align*}
\alpha_t &= \alpha_t^{SM} + \alpha_t^{BLHM}, \\
\alpha_t^W &= \alpha_t^{W-SM} + \alpha_t^{W-BLHM}. \quad \text{(47)}
\end{align*}
\]

4 Numerical results

For our numerical analysis of the electromagnetic and weak properties of the tau-lepton in the context of the SM and BLHM, we briefly review the free parameters of the BLHM. Subsequently, we discuss the numerical contributions generated for the AMDM and AWMDM of the \( \tau \)-lepton in each study scenario.

4.1 Parameters space of the BLHM

We consider the following BLHM input parameters: \( m_{A_0}, m_{h_0}, \tan \beta, \tan \theta_g, f \) and \( F \).

The pseudoscalar mass \( A_0 \): This parameter is fixed around 1000 GeV, our choice is consistent with the current search results for new scalar bosons [50]. Data recorded by the ATLAS experiment at the LHC, corresponding to an integrated luminosity of 139 fb\(^{-1}\) from proton-proton collisions at a center-of-mass energy 13 TeV, were used to search for a heavy Higgs boson, \( A_0 \), decaying into \( ZH \), where \( H \) denotes another heavy Higgs boson with mass \( m_H > 125 \text{ GeV} \).

The scalar mass \( h_0 \): In the BLHM scenario, the free parameters \( m_{A_5, A_6} \) [41] are introduced to break all the axial symmetries in the Higgs potential, giving positive masses to all scalars. Specifically, the \( h_0 \) scalar receives a mass equal to \( m_4 = m_{h_0} = 100 \text{ GeV} \), according to the BLHM, and the restriction \( m_4 > 10 \text{ GeV} \) must be considered [41].

The ratio of the VEVs of the two Higgs doublets, \( \tan \beta \): Several theoretical constraints can be applied to this parameter, primarily due to perturbativity requirements. Two constraints limit the value of \( \tan \beta \), the first of which is the requirement that \( \lambda_0 < 4\pi \), leading to an upper bound according to Eq. (50). A lower bound also exists and is set by examining the radiatively induced contributions to \( m_1 \) and \( m_2 \) in the model, which suggests that \( \tan \beta > 1 \) [41].

From this inequality, we can find the range of allowed values for the parameter \( \tan \beta \). In particular, for \( m_{A_0} = 1000 \text{ GeV} \), it is obtained that \( 1 < \tan \beta < 10.45 \).

The mixing angle \( \theta_g \): The gauge couplings \( g_A \) and \( g_B \), associated with the \( SU(2)_L \times SU(2)_R \) gauge bosons, can be parametrized in a more phenomenological fashion in terms of a mixing angle \( \theta_g \) and the \( SU(2)_L \) gauge coupling:

\[
\tan \theta_g = \frac{g_A}{g_B} \quad \text{(50)}
\]

For simplicity, it is assumed that \( \tan \theta_g = 1 \) [44], which implies that the gauge couplings \( g_A \) and \( g_B \) are equal. The \( g^{A,B} \) values are generated using the restriction \( g = 0.6525 \).

Symmetry breaking scale \( f \): The BLHM features a global \( SO(6)_A \times SO(6)_B \) symmetry that is broken to a diagonal \( SO(6)_V \) at a scale \( f \sim O(\text{TeV}) \) when a nonlinear sigma field, \( \sum \), develop a VEV. Bounds on the \( f \) scale arise when \( \tan \beta \) limits, fine-tuning constraints on the heavy quark masses, and experimental restrictions from producing of heavy quarks are considered. Refs. [42] and [51] establish that \( f \in [700, 3000] \text{ GeV} \).

Symmetry breaking scale \( F \): A second global symmetry of the \( SU(2)_C \times SU(2)_R \) form is also present in the BLHM, and is broken to a diagonal \( SU(2) \) at a scale \( F > f \) when a second nonlinear sigma field, \( \Delta \), develops a VEV. Due to the characteristics of the BLHM, the energy scale \( F \) acquires sufficiently large values compared to the \( f \) scale. The purpose is to ensure that the new gauge bosons are much heavier than the exotic quarks. In this way, \( F \in [3000, 6000] \text{ GeV} \) [41,42].

To predict the estimates of the AMDM and AWMDM of the tau-lepton, in Table 3, we summarize the values used for the parameters involved in our analysis.
Table 3: Values assigned to the free parameters involved in our numerical analysis in the context of the BLHM

| Parameter | Value                  |
|----------|------------------------|
| $m_{A_0}$ | 1000 GeV               |
| $m_{A^0}$ | 100 GeV                |
| $\tan \beta$ | 3                     |
| $\tan \theta_g$ | 1                    |
| $f$      | [1000, 3000] GeV       |
| $F$      | [3000, 6000] GeV       |

4.2 AMDM of the tau-lepton at the BLHM

At the one-loop level, the electromagnetic properties of the tau-lepton are induced by the scalar and vector bosons of the BLHM via the Feynman diagrams of Fig. 1. The contributions generated by these diagrams are classified into three types for analysis: scalar, vector, and scalar–vector. Below, we focus on the potential effects of the new particles that contribute to the AMDM of tau-lepton, as they could generate a significant enhancement in the value of $\alpha_t$ ($\alpha_t \equiv a_t^{BLHM}$) compared to the SM prediction $\alpha_t^{SM}$. In the BLHM, as in the SM, the $\tau$ EDM is multiloop suppressed. Therefore, in this subsection, we report only the values of $\alpha_t$.

For this purpose, we start by solving the amplitudes generated by Eqs. (40)–(44), the method we use to solve is the Passarino–Veltman reduction scheme. As indicated above, Table 3 assigns values to the free parameters involved in our numerical analysis. The parameter $\tan \theta_g = g_A/g_B$ is of particular interest since in this paper, as in Ref. [44], it is assumed for simplicity that $\tan \theta_g = 1$ which implies that the gauge couplings $g_A$ and $g_B$ are equal. Another possible study scenario is to choose $\tan \theta_g \neq 1$ (sin $\theta_g \neq \cos \theta_g$). In this case, we can predict that the values for $\alpha_t$ and $a_t^{SM}$ do not change significantly in this new scenario. As will be shown later, the reason for this is that the Feynman rules for vertices that involve diagrams that provide the largest contributions (see Figs. 1a and 2a), that is, the terms that contain sin $\theta_g$ and cos $\theta_g$ are inversely proportional to $(f^2 + F^2)$ (see Table 9 in Appendix A), and therefore suppress these additional contributions since $f \in [1000, 3000]$ GeV and $F \in [3000, 6000]$ GeV. When $\tan \theta_g = 1$, the Feynman rules for the $A_\gamma W^+\phi^-$ and $A_\gamma W^+\eta^-$ vertices, as well as their respective Hermitian conjugates, are canceled (see Table 10 in Appendix A). Thus, they lead to the non-contribution of specific Feynman diagrams shown in Fig. 1d, e.

After solving for the amplitudes, we extract the form factors proportional to the $\sigma^{\mu\nu}q_\nu$ tensor, these form factors contain in coded away the $[\alpha_t]^{S_{\pm}V_{\pm}}$, $[\alpha_t]^{V_{\pm}V_{\pm}}$ and $[\alpha_t]^{S_{\pm}V_{\pm}V_{\pm}}$. Concerning $[\alpha_t]^{S_{\pm}V_{\pm}}$ that represents the scalar–vector contributions to the AMDM of the $\tau$-lepton, its corresponding form factors turn out to be zero. Therefore, $[\alpha_t]^{S_{\pm}V_{\pm}}$ has no effect on $\alpha_t$. The only non-zero contributions to the AMDM $\alpha_t$ of the tau-lepton arise due to the scalar contributions and vector contributions shown in Fig. 1a and 1b, c, respectively.

In Fig. 3, we show the partial contributions to $\alpha_t$ due to the different particles involved, and these individual contributions are classified in $\alpha_t(S_{\pm})$ and $\alpha_t(V_{\pm})$, depending on the energy scale $f$ and generate purely real values. Specifically, Fig. 3a shows the curves of the contributions generated by the scalars $\eta^0$, $A_0$, $\phi^0$, $\sigma$ and $H_0$. In this figure, we can appreciate that the scalar $\eta^0$ provides the largest positive contribution with $Re[\alpha_t(\eta^0)] = [2.22 \times 10^{-11}, 2.43 \times 10^{-12}]$ while the smallest negative contribution is given by the $H_0$ scalar with $Re[\alpha_t(H_0)] = [-2.24, 2.27] \times 10^{-12}$. The remaining scalars generate suppressed contributions, one or more orders of magnitude smaller compared to the main contribution $Re[\alpha_t(\eta^0)]; Re[\alpha_t(A_0)] = [2.72, 2.67] \times 10^{-12}$, $Re[\alpha_t(\phi^0)] = [1.07 \times 10^{-12}, 7.82 \times 10^{-14}]$ and $Re[\alpha_t(\sigma)] = [2.09 \times 10^{-14}, 2.96 \times 10^{-16}]$. On the other hand, the vector contributions arise from the gauge bosons $W^\pm$ and $Z'$ (see Fig. 3b). So for the range of analysis set for the symmetry breaking scale $f$, the contribution of the gauge bosons $W^\pm$ and $Z'$ are $Re[\alpha_t(W^\pm)] = [9.81, 6.67] \times 10^{-10}$ and $Re[\alpha_t(Z')] = [3.92, 2.67] \times 10^{-10}$, respectively. According to Fig. 3a, b, we observe that the main partial contribution to $Re[\alpha_t]$ is generated by the $W^\pm$ gauge boson. We also notice that as the energy scale $f$ takes values closer to 3000 GeV, the values of $Re[\alpha_t]$ become smaller and smaller. In Table 4 we show the magnitudes of all partial contributions to $\alpha_t$ that correspond to the virtual particles circulating in the $\gamma \tau^+\tau^-$ vertex loop.

In Fig. 4, we also describe the behavior of $Re[\alpha_t(\text{scalar})]$ and $Re[\alpha_t(\text{vector})]$, as well as the total of these two contributions. $Re[\alpha_t(\text{scalar})]$ and $Re[\alpha_t(\text{vector})]$ stand for the sum of all individual contributions to $Re[\alpha_t]$ due to the scalar and vector bosons, respectively. Note that the magnitude of the vector contribution dominates concerning the scalar contribution so that the total contribution receives significant contributions from the vector sector. The numerical estimates obtained for the three sectors are $Re[\alpha_t(\text{vector})] = [1.37 \times 10^{-9}, 9.34 \times 10^{-10}], Re[\alpha_t(\text{scalar})] = [2.38 \times 10^{-11}, 2.90 \times 10^{-12}]$ and $Re[\alpha_t(\text{total})] = [1.40 \times 10^{-9}, 9.37 \times 10^{-10}]$ for $f = [1000, 3000]$ GeV. According to these numerical data, we find that effectively the vector and total contribution acquire values of the same order of magnitude, which does not occur with the scalar contribution, which generates slightly small contributions, thus interfering very weakly with the total contribution.

Until now, the sensitivity of the total AMDM of the tau-lepton has been measured by varying the first symmetry breaking scale $f$. However, it also depends on the second symmetry breaking scale $F$. Therefore, it is worthwhile to examine the dependence of $\alpha_t$ on the scale $F$. Thus, in Fig. 5a, we show the level of sensitivity exhibited by the
AMDM are energy scales, we find that the numerical predictions in the scale are $1000, 2000$ and $3000$ GeV. For the three distinct

$$\tau$$

AMDM when varying the $F$ energy scale while keeping the $f$ scale fixed, the fixed values assigned to the $f$ scale are $1000, 2000$ and $3000$ GeV. For the three distinct energy scales, we find that the numerical predictions in the $\tau$ AMDM are $\text{Re}(\alpha_{\tau}) = [2.36 \times 10^{-9}, 6.54 \times 10^{-10}]$, $\text{Re}(\alpha_{\tau}) = [1.80 \times 10^{-9}, 5.89 \times 10^{-10}]$ and $\text{Re}(\alpha_{\tau}) = [1.30 \times 10^{-9}, 5.21 \times 10^{-10}]$, respectively. It is important to note that these contributions to $\alpha_{\tau}$ acquire only real values and are all of the same order of magnitude, $10^{-9}-10^{-10}$. These values decrease drastically as the $F$ scale increases up to $6000$ GeV. As we observed in the plot, the dominant contribution arises for small values of the $f$ scale, particularly when $f = 1000$ GeV. Concerning, Fig. 5b, we plot the curves of the contributions to $\alpha_{\tau}$ in the analysis range of $f = [1000, 3000]$ GeV, now we fix the scale $F$ and assign values such as $3000, 4000, 5000$ and $6000$ GeV. For these fixed values of $F$, we explore the sensitivity of $\text{Re}(\alpha_{\tau})$ and find that the corresponding numerical estimates are $\text{Re}(\alpha_{\tau}) = [2.36, 1.30] \times 10^{-9}$, $\text{Re}(\alpha_{\tau}) = [1.40 \times 10^{-9}, 9.37 \times 10^{-10}]$, $\text{Re}(\alpha_{\tau}) = [9.21, 6.89] \times 10^{-10}$ and $\text{Re}(\alpha_{\tau}) = [6.54, 5.21] \times 10^{-10}$. Again, $\text{Re}(\alpha_{\tau}) \sim 10^{-9}-10^{-10}$ and also acquires large values for small values of the $F$ scale, this being $F = 3000$ GeV. By comparison, we find that $\text{Re}(\alpha_{\tau})$ takes values of the same order of magnitude if $F$ is varied while $f$ is fixed or the opposite. Although specifically, $\text{Re}(\alpha_{\tau})$ obtains larger values when $f = 1000$ GeV or $F = 3000$ GeV.

We now turn to examine the behavior of the real part of $\alpha_{\tau}$ as a function of the mass of the pseudoscalar $A_0$ or the charged scalar $H^\pm$, which by the particular char-

Fig. 5  
\(a\) Total contribution to \(\text{Re}(a_\tau)\) for different values of the energy scale \(f\). \(b\) Total contribution to \(\text{Re}(a_\tau)\) for different values of the energy scale \(F\). The plots are obtained for specific fixed values of the \(f\) or \(F\) scale. The values provided in Table 3 are used for the remaining parameters of the model.

Fig. 6  Total contribution to \(\text{Re}(a_\tau)\) for different values of \(\tan \beta\). The plot is obtained with fixed values of the \(f = 1000\) GeV and \(F = 4000\) GeV. The values provided in Table 3 are used for the remaining parameters of the model.

Characteristics of the BLHM \(m_{A_0} = m_{H^\pm}\). In this case, we are interested in investigating the phenomenological details associated with the increase of \(m_{A_0}\) (or \(m_{H^\pm}\)) vs. \(\text{Re}(a_\tau)\). According to Eq. (50), the parameter \(\tan \beta\) is directly related to \(m_{A_0}\), since the range of values that \(\tan \beta\) could take is established precisely by the value assigned to \(m_{A_0}\), i.e., for \(m_{A_0} = 1000\) GeV and \(m_{A_0} = 1500\) GeV the respective ranges of values for the parameter \(\tan \beta\), \(\tan \beta \in (1, 10.45)\) and \(\tan \beta \in (1, 11.99)\) are generated. To evaluate the numerical contributions of \(\text{Re}(a_\tau)\), we propose to vary the \(m_{A_0}\) parameter from 1000 GeV to 1500 GeV and also take certain values of \(\tan \beta\) in the allowed value space, that is, \(\tan \beta = 3, 4, 6, 8\) and 10. Figure 6 shows the dependence of \(\text{Re}(a_\tau)\) on \(m_{A_0}\), we observe that the main signal is reached for \(\tan \beta = 3\) while the lowest signal is obtained for \(\tan \beta = 10\), \(\text{Re}(a_\tau) = [1.3971, 1.3968] \times 10^{-9}\) and \(\text{Re}(a_\tau) = [1.3969, 1.3967] \times 10^{-9}\), respectively. For the remaining curves, \(\text{Re}(a_\tau) \sim 10^{-9}\). According to our predictions, \(\text{Re}(a_\tau)\) shows a dependence on the \(m_{A_0}\) parameter. However, \(\text{Re}(a_\tau)\) has a small sensitivity to changes in the parameter \(\tan \beta\) since the numerical values obtained by \(\text{Re}(a_\tau)\) are of the same order of magnitude for different choices in the values of \(\tan \beta\).

4.3 AWMDM of the tau-lepton at the BLHM

In this subsection, we perform the numerical estimation of the AWMDM \(a^W_\tau (a^W_\tau \equiv a^WBLHM_\tau)\) of the tau-lepton induced by a scalar, vector and scalar–vector bosons of the BLHM depicted in Fig. 2a, b, c and d, e, respectively. As in Sect. 4.2, in the \(\tan \theta_g = 1\) scenario implying that \(\sin \theta_g = \cos \theta_g\) leads to the cancellation of some Feynman diagrams in Fig. 2d, e, this is because the Feynman rules for the involved vertices \(Z W^+ \phi^-\), \(Z W^+ \eta^-\) and \(Z \mu Z' \eta H\) are made zero by the condition mentioned above (see Table 10 in Appendix A). The remaining Feynman diagrams provide non-zero contributions to \(a^W_\tau\).

In this sense, we start by showing in Fig. 7 the contributions of the different scalars to the \(\tau\) AWMDM, here and in the subsequent cases \(a^W_\tau\) acquire a real part and an imaginary part. We plot the behavior of \(a^W_\tau\) as a function of the new physical scale \(f\) for the interval \(f = [1000, 3000]\) GeV, while the other parameters assume fixed values. In the left plot of Fig. 7, it can see that the great majority of the scalars involved gener-
Fig. 7 Individual scalar contributions to $a_W^\tau$. a $\text{Re}(a_W^\tau)$. b $\text{Im}(a_W^\tau)$. The plots are obtained with the fixed value of $F = 4000$ GeV. The values provided in Table 3 are used for the remaining model parameters.

ate positive contributions to $\text{Re}[a_W^\tau]$, and only the $H_0$ and $\sigma$ scalars contribute negatively. Of all the scalars, the heaviest of them is $\sigma$ and it contributes quite small values to $\text{Re}[a_W^\tau]$, $|\text{Re}[a_W^\tau(\sigma)]| = [5.16 \times 10^{-16}, 8.20 \times 10^{-18}]$. In contrast, the scalars $\eta^\pm$ and $H^\pm$ generate the main contributions to $\text{Re}[a_W^\tau]$ in the range of analysis established for the $f$ energy scale, i.e., $\text{Re}[a_W^\tau(\eta^\pm)] = [1.38 \times 10^{-13}, 9.51 \times 10^{-14}]$ for the interval $f = [1000, 1100]$ GeV and $\text{Re}[a_W^\tau(H^\pm)] = (9.51, 9.35) \times 10^{-14}$ for $f = (1100, 3000)$ GeV. Concerning the right plot of Fig. 7, it can be observed that again the $H_0$ and $\sigma$ scalars contribute negatively, in this case to $\text{Im}(a_W^\tau)$, while the rest of the scalars contribute positively. The $\eta^0$ scalar provides the largest contributions to $\text{Im}[a_W^\tau]$, while the smallest contribution is induced by $\sigma$: $\text{Im}[a_W^\tau(\eta^0)] = [3.28 \times 10^{-13}, 3.58 \times 10^{-14}]$ and $\text{Im}[a_W^\tau(\sigma)] = [1.14 \times 10^{-16}, 1.38 \times 10^{-18}]$.

We discuss the contributions induced by the vector and scalar–vector bosons to the $\tau$ AWMDM. We begin by examining the real and imaginary parts of the BLHM partial contributions to $a_W^\tau$. Thus, from Fig. 8, we can see that all the generated contributions are positive except the real part of the scalar–vector contribution, induced by $Z$ and $H_0$. The dominant contributions for both the real and imaginary part of $a_W^\tau$ are achieved when the vector boson $W'^\pm$ circulates.
The magnitude of the partial contributions to $a_t^W$ of the BLHM. The data are obtained by fixing the $f$ and $F$ scales, $f = 1000$ GeV and $F = 4000$ GeV. The values provided in Table 3 are used for the rest of the model parameters. $abc$ denotes the different particles running in the loop of the vertex $Z \tau^+ \tau^-$. 

$F = 1000$ GeV, $F = 4000$ GeV

in the $Z \tau^+ \tau^-$ vertex loop. In this case, the corresponding numerical contributions are $\text{Re}[a_t^W(W^{\pm})] = [2.72, 1.85] \times 10^{-9}$ and $\text{Im}[a_t^W(W^{\pm})] = [9.01, 4.16] \times 10^{-13}$. Other subdominant contributions appear when particles $W^{\pm} \phi^-$, $\phi^+ W^-$ and $Z'$ circulate in the above-mentioned vertex loop: $\text{Re}[a_t^W(W^{\pm} \phi^-)] = \text{Re}[a_t^W(\phi^+ W^-)] = [4.67, 3.23] \times 10^{-10}$ and $\text{Im}[a_t^W(Z')] = [2.42, 1.12] \times 10^{-13}$. Complementarily, the minor contributions arise for the following cases: $\text{Re}[a_t^W(Z H_0)] = [5.69, 5.83] \times 10^{-12}$ and $\text{Im}[a_t^W(Z H_0)] = \text{Im}[a_t^W(W^{\pm} \phi^-)] = \text{Im}[a_t^W(W^{\pm} \eta^-)] = 0$. If we compare our numerical estimates, we find that the real parts of the partial contributions provide significant contributions to $a_t^W$ since they are at least one order of magnitude larger than the imaginary parts. In Table 5, we show the magnitudes of all partial contributions to $a_t^W$ that correspond to the virtual particles circulating in the $Z \tau^+ \tau^-$ vertex loop.

In the following, we show the curves that represent the sum of all individual contributions due to the scalar and vector bosons and the scalar–vector contributions. The magnitude of these contributions is shown in Fig. 9. Here, we observe that the total vector contribution dominates over the scalar and scalar–vector contributions since the latter are suppressed. With respect to the real part of $a_t^W$ depicted in Fig. 9a, we can observe more closely that $\text{Re}[a_t^W(\text{total})]$ and $\text{Re}[a_t^W(\text{vector})]$ obtain values of the same order of magnitude, $10^{-9}$, while $\text{Re}[a_t^W(\text{s-v})] = 10^{-10}$ and $\text{Re}[a_t^W(\text{scalar})] = 10^{-13}$. With the imaginary part of $a_t^W$ (see Fig. 9b) the same happens as the real part, in this case, $\text{Im}[a_t^W(\text{total})] \sim \text{Im}[a_t^W(\text{vector})] \sim 10^{-12} - 10^{-13}$, $\text{Im}[a_t^W(\text{scalar})] \sim 10^{-13} - 10^{-14}$ and $\text{Im}[a_t^W(\text{s-v})] = 0$. It is worth mentioning that Fig. 9(ab) were obtained for a fixed value of the other physical scale of the BLHM, $F = 4000$ GeV, which is also involved in our calculations. We later present the sensitivity of $a_t^W$ for other values of the $F$ scale.

As already commented, the BLHM is based on two distinct global symmetries that break into diagonal subgroups at different scales, $f$ and $F > f$. These scales represent the scales of the new physics. Therefore, it is very convenient to analyze the behavior of the $\tau$ AWMDM as a function of these energy scales since the masses of the new scalar and vector bosons strongly depend on them. Thus, similar to what was performed in the previous subsection, we study the dependence of $a_t^W$ on $F$ while maintaining fixed the $f$ scale or the opposite. In Fig. 10, we begin by showing a variation of the scale $F$ from 3000 GeV to 6000 GeV for three different $f$ energy scales, i.e., $f = 1000$ GeV, 2000 GeV, 3000 GeV. In this plot, we appreciate that the main contributions to $a_t^W$ arise for $f = 1000$ GeV. This occurs for both the real and the imaginary part of $a_t^W$: $\text{Re}[a_t^W] = [6.64, 1.80] \times 10^{-9}$ and $\text{Im}[a_t^W] = [3.68 \times 10^{-12}, 6.00 \times 10^{-13}]$, respectively. On the other hand, the weakest contributions appear when the scale $f$ takes larger values, especially when $f = 3000$ GeV: $\text{Re}[a_t^W] = [3.71, 1.47] \times 10^{-9}$ and $\text{Im}[a_t^W] = [1.06 \times 10^{-12}, 2.05 \times 10^{-13}]$.

Now, we examine the dependence of $a_t^W$ on the $f$ scale for certain fixed values of the $F$ scale, i.e., $F = 3000$ GeV, 4000 GeV, 5000 GeV, 6000 GeV. With these values of $F$, we plot the curves shown in Fig. 11. In this case, the largest contributions to $a_t^W$ are reached for $F = 3000$ GeV, these contributions are $\text{Re}[a_t^W] = [6.64, 3.71] \times 10^{-9}$ and $\text{Im}[a_t^W] = [3.68, 1.06] \times 10^{-12}$. On the opposite side, the smallest contributions to $a_t^W$ are generated when $F = 6000$ GeV: $\text{Re}[a_t^W] = [1.80, 1.47] \times 10^{-9}$ and $\text{Im}[a_t^W] = [6.00, 2.05] \times 10^{-13}$.

According to the numerical results, it is found that $a_t^W$ is sensitive to a slight change in the values of the $f$ and $F$ scales, this occurs as long as these parameters are in the established intervals. When $a_t^W$ depends on $F$, we observe that $a_t^W$ has a decrease of about one order of magnitude as $F$ increases up to 6000 GeV. For the following case, when $a_t^W$ depends on $f$, we also have a decrease of at most one order of magnitude as $f$ reaches 3000 GeV. In summary, we can affirm that $a_t^W$ gets large values when $f = 1000$ GeV or $F = 3000$ GeV, while smaller values are obtained for $a_t^W$ when the scales tend to take values close to their established upper limits. In short, $a_t^W = 6.64 \times 10^{-9} + 3.68 \times 10^{-12} i$ is the largest value found when $f = 1000$ GeV and $F = 3000$ GeV.

Finally, Fig. 12 show the $a_t^W$ behavior as a function of $m_{A_0}$ or $m_{H^\pm}$, for tan $\beta = 3, 4, 6, 8$ and 10. From this fig-
Fig. 9 Scalar–vector (s–v), scalar, vector, and total contributions to $a_W^{\tau}$. a Re($a_W^{\tau}$). b Im($a_W^{\tau}$). The plots are obtained with the fixed value of $F = 4000$ GeV. The values provided in Table 3 are used for the remaining model parameters.

Fig. 10 Total contribution to $a_W^{\tau}$ for different values of the energy scale $f$. a Re($a_W^{\tau}$). b Im($a_W^{\tau}$). The plots are obtained for specific fixed values of the $f$ scale. The values provided in Table 3 are used for the remaining parameters of the model.

ure, we can observe that the largest contributions to the $\tau$ AWMDM arise when $\tan \beta = 3$. This happens for the real and imaginary part of $a_W^{\tau}$: Re[$a_W^{\tau}$] = [3.91307, 3.91301] × $10^{-9}$ and Im[$a_W^{\tau}$] = [1.50892, 1.50353] × $10^{-12}$. As the parameter, $\tan \beta$, increases more suppressed curves are generated. This occurs in the case of $\tan \beta = 10$ which gives the following values corresponding to $a_W^{\tau}$, Re[$a_W^{\tau}$] = [3.91298, 3.91297] × $10^{-9}$ and Im[$a_W^{\tau}$] = [1.50500, 1.50288] × $10^{-12}$. Furthermore, $a_W^{\tau}$ acquires smaller values as the mass of the pseudoscalar $A_0$ increases up to 1500 GeV. However, we can say that the changes or effects on $a_W^{\tau}$ are not so great since the numerical values they acquire remain of the same order of magnitude.

4.4 Contributions of the SM and BLHM to the AMDM and AWMDM of the tau-lepton

As previously defined (Eqs. (48) and (49)), the contribution of the SM and BLHM particles to the AMDM and AWMDM of the tau-lepton will be represented by $\alpha_\tau$ and $\alpha_W^{\tau}$, respectively. In this way, in Tables 6 and 7 we provide the partial and total numerical values for $\alpha_\tau$ and $\alpha_W^{\tau}$. In these tables, we find that all new diagrams arising in the BLHM have a small numerical impact on the AMDM and AWMDM of the $\tau$-lepton. This is partly because both $\alpha_\tau$ and $\alpha_W^{\tau}$ acquire values inversely proportional to the energy scales $f$ and $F$. Only some partial contributions are comparable to the SM partial contributions (see Appendix B) but not larger than them. The SM particles...
provide the largest contributions to $\alpha_\tau$ and $\alpha_\tau^W$. According to the numerical data, we find that $\alpha_\tau = 116090.46 \times 10^{-8}$ and $\alpha_\tau^W = -1.92 \times 10^{-6} - 0.57 \times 10^{-6} i$.

5 Conclusions

We have calculated the contributions generated by the SM (see Appendix B) and BLHM particles to the AMDM and AWMDM of the tau-lepton at the one-loop level. Within the SM, we find that our predictions for $a_{\nu}^{SM}$ and $a_{\nu}^{W-SM}$ are in agreement with the results reported in the literature. Concerning the new physics, this arises in the BLHM scenario and is induced by the new scalar and vector bosons. The new contributions that these generate to $a_{\tau}$ and $a_{\tau}^W$ are emphasized.

The BLHM has two global symmetries that break at different energy scales, so $f$ and $F$ represent the scales of the new physics, and at this level, the new scalar and vector bosons acquire their respective masses. Therefore, we have analyzed the dependence of $a_{\tau}$ and $a_{\tau}^W$ on the physical scales $f$ and $F$, and we find that both $a_{\tau}$ and $a_{\tau}^W$ are sensitive to changes in $f$ and $F$. Large values of these energy scales, as long as they are in the allowed intervals, sup-
press the contributions to \(a_\tau\) and \(a_\tau^W\). However, when these scales acquire the respective minimum values, \(f = 1000\) GeV and \(F = 3000\) GeV, large values are reached for the \(\tau\) AMDM and AWMDM: \(a_\tau = 2.36 \times 10^{-9} + 0i\) and \(a_\tau^W = 6.64 \times 10^{-9} + 3.68 \times 10^{-12}i\), respectively. In this work, we also examine the dependence of \(a_\tau\) and \(a_\tau^W\) on the \(m_{A_0}\) parameter. Our results indicate that both show a small sensitivity to changes in the \(m_{A_0}\) parameter since the contributions they acquire remain of the same order of magnitude, \(a_\tau \sim 10^{-9}\) and \(a_\tau^W \sim 10^{-9}\).

It is interesting to study the contributions of the new physics as they could significantly improve the AMDM and AWMDM of the tau-lepton. This is because, for now, the sensitivity reached by the colliders is beyond the level of precision required to test the SM predictions on \(a_\tau\) and \(a_\tau^W\). Therefore, it is worth studying the effects of new particles not described by the SM as they could generate potentially significant contributions and be within reach of future experimental measurements. In the BLHM scenario, we found that the contributions generated by the new scalar and vector bosons to the \(\tau\) AMDM and AWMDM are \(a_\tau \sim 10^{-9}\) and \(a_\tau^W \sim 10^{-9}\). These numerical values are smaller than the SM contributions. However, they are similar in size and even more significant than those arising in some SM extensions, such as the Simplest Little Higgs model, \(a_\tau \sim 10^{-9}\) and \(a_\tau^W \sim 10^{-9}\) [52]; the Two-Higgs Doublet models (type-I and type-II), \(a_\tau^W \sim 10^{-9} - 10^{-10}\) [53,54]; the Two-Higgs Doublet model-type-III with textures, \(a_\tau \sim 10^{-7} - 10^{-8}\) and \(a_\tau^W \sim 10^{-7} - 10^{-10}\) [55]; Scalar Leptoquark models, \(a_\tau \sim 10^{-9}\) and \(a_\tau^W \sim 10^{-9}\) [56]; the Minimal Supersymmetric Standard Model with a mirror fourth generation, \(a_\tau \sim 10^{-6} - 10^{-10}\) [57]; unparticle physics (for \(U = 10\) TeV), \(a_\tau \sim 10^{-9} - 10^{-10}\) and \(a_\tau^W \sim 10^{-9} - 10^{-10}\) [58]; the type-I and type-III seesaw models, \(|a_\tau^I| < 1.87 \times 10^{-8}\) and \(|a_\tau^III| < 7.55 \times 10^{-9}\) [59]; and finally, in the framework of the effective lagrangian approach and the Fritzsch–Xing lepton mass matrix, \(a_\tau \sim 10^{-11}\) [60].

Currently, the experimental limits in the \(\tau\) AMDM and AWMDM are well above theoretical predictions. Our results are also outside the detection range of future experiments, so there is insufficient sensitivity to be tested and cross-checked with experimental values. The results presented here complement other studies performed on models with an extended scalar sector and may be helpful to the scientific community.

### Appendix A: The Feynman rules for the BLHM

In this appendix, we present the Feynman rules for the BLHM involved in our calculation for the AMDM and AWMDM of the tau-lepton. It is convenient to define the following useful notation:

\[
\begin{align*}
    c_\beta &= \cos \beta, \\
    s_\beta &= \sin \beta, \\
    c_\alpha &= \cos \alpha, \\
    s_\alpha &= \sin \alpha, \\
    c_g &= \cos \theta_G, \\
    s_g &= \sin \theta_G, \\
    x_s &= \frac{1}{2 \cos \theta_W} \sin \theta_G \cos \theta_G (\sin^2 \theta_G - \cos^2 \theta_G), \\
    y_\tau &= \frac{m_\tau}{v \sin \beta} \left(1 - \frac{v^2}{3 f^2}\right)^{-1/2}.
\end{align*}
\]

**Table 8** Feynman rules for the BLHM involving the escalar $\sigma$, $h_0$, $H_0$, $\phi^0$, $\eta^0$, $W^\pm$, $\phi^\pm$, $\eta^\pm$, the pseudoscalar $A_0$ and the vector bosons $Z'$ and $W'^\pm$.

Fig. 13 Generic Feynman diagrams that contributes to the AMDM of the tau-lepton, \( l_i \equiv \tau, \nu_\tau \). a Scalar contribution, \( S_i \equiv h_0 \). b, c Vector contributions, \( V_i \equiv \gamma, Z \).

Fig. 14 Generic Feynman diagrams that contributes to the AWMDM of the tau-lepton, \( l_i \equiv \tau, \nu_\tau \). a Scalar contribution, \( S_i \equiv h_0 \). b, c Vector contributions, \( V_i \equiv \gamma, Z \). d Scalar–vector contribution.
Table 11 Partial contributions to $a^{SM}_{\gamma\tau\tau}$. $abc$ denotes the different particles running in the loop of the vertex $\gamma\tau^+\tau^-$

| Couplings abc | $(a^{SM}_{\gamma\tau\tau})^{abc}$ | Value |
|---------------|---------------------------------|--------|
| $\gamma\tau\tau$ | $1.16140.97 \times 10^{-8} + 0i$ | |
| $Z\tau\tau$ | $51.55 \times 10^{-8} + 0i$ | |
| $h_0\tau\tau$ | $0.09 \times 10^{-8} + 0i$ | |
| $\nu_\tau W^+W^-$ | $-102.29 \times 10^{-8} + 0i$ | |
| Total | $a^{SM}_{\gamma\tau\tau} = 1.16090.33 \times 10^{-8} + 0i$ | |

Table 12 Partial contributions to $a^{W-SM}_{\gamma\tau\tau}$. $abc$ denotes the different particles running in the loop of the vertex $\gamma\tau^+\tau^-$

| Couplings abc | $(a^{W-SM}_{\gamma\tau\tau})^{abc}$ | Value |
|---------------|---------------------------------|--------|
| $\gamma\tau\tau$ | $3.09 \times 10^{-7} - 1.24 \times 10^{-7} i$ | |
| $Z\tau\tau$ | $4.03 \times 10^{-8} + 1.86 \times 10^{-8} i$ | |
| $h_0\tau\tau$ | $-6.72 \times 10^{-12} - 1.38 \times 10^{-11} i$ | |
| $W^\pm W^\mp \nu_\tau$ | $-9.14 \times 10^{-7} - 4.66 \times 10^{-7} i$ | |
| $\nu_\tau W^+W^-$ | $-1.37 \times 10^{-6} + 0 i$ | |
| $\tau h_0 Z$ | $1.35 \times 10^{-8} + 0i$ | |
| Total | $a^{W-SM}_{\tau\tau\tau} = -1.92 \times 10^{-6} - 0.57 \times 10^{-6} i$ | |

is $-1.9193 \times 10^{-6} - 0.5713 \times 10^{-6} i$. Our result is comparable to that reported in Ref. [33], although a slight difference prevails. This is due to the fact that we used current values for the input parameters $m_Z$, $m_W$, $m_\tau$, $\sin \theta_W$, and $\alpha$ (fine-structure constant).
