Another infinite tri-Sasaki family and marginal deformations

O. P. Santillan *

Abstract

Several Einstein-Sasaki 7-metrics appearing in the physical literature are fibered over four dimensional Kahler-Einstein metrics. Instead we consider here the natural Kahler-Einstein metrics defined over the twistor space \( Z \) of any quaternion Kahler 4-space, together with the corresponding Einstein-Sasaki metrics. We work out an explicit expression for these metrics and we prove that they are indeed tri-Sasaki. Moreover, we present an squashed version of them which is of weak \( G_2 \) holonomy. We focus in examples with three commuting Killing vectors and we extend them to supergravity backgrounds with \( T^3 \) isometry, some of them with \( AdS_4 \times X_7 \) near horizon limit and some others without this property. We would like to emphasize that there is an underlying linear structure describing these spaces. We also consider the effect of the \( SL(2,R) \) solution generating technique presented by Maldacena and Lunin to these backgrounds and we find some rotating membrane configurations reproducing the E-S logarithmic behaviour.

1. Introduction

A duality between quantum field theories and strings was proposed by t’ Hooft in [1], where it was noticed that any Feynman diagram of an \( U(N) \) gauge theory with matter fields can be drawn over a two dimensional surface. Few of these diagrams corresponds to
a plane or to an sphere, higher diagrams are drawn over a surface with non trivial genus, such as the torus. Any closed line contribute with a factor $N$ to the amplitude. The partition function results in an expansion in terms of the form $c_g(\lambda)N^{2-2h}$ being $h$ the genus (or the number of holes) of the two dimensional surface and $c_g(\lambda)$ certain function of the t Hooft coupling $\lambda = g^2 N$. In the large $N$ limit and keeping fixed $\lambda$ the powers $N^{2-2h}$ goes all to zero except for diagrams with $h = 0, 1$. For this reason this limit is called the planar limit. If $\lambda << 1$ then $g << 1$, this corresponds to the perturbative regime. On the other hand for $\lambda >> 1$ the amplitudes have been found to be a sum of terms of the form $A_g(\lambda)g^{h-1}$. In the practise $N = 3$ can be considered as a large number of colours and this expansion corresponds to non perturbative phenomena [1]-[2]. If in addition the variable $\lambda$ became large then more diagrams contribute and become dense in the sphere. It was suggested [1] that this diagrammatic expansion is describing a discrete version of an string theory in which $A_g$ is interpreted as a closed string amplitude. These string theory is defined as the result of summing all the planar diagrams.

This duality between strings and gauge theories was developed further in [3] and leaded to the AdS/CFT correspondence. As is well known, D-branes are solitonic objects in superstring theory which admit a gauge/gravity low energy interpretation. This is because the low energy dynamic of massless open string states on a Dp brane is, at first order, a $(p+1)$-dimensional supersymmetric gauge theory, and in the closed string channel a Dp brane is a solution of the low energy supergravity solution in presence of a $C_p$ Rammond-Rammond p-form. The Yang Mills coupling constant is related to the string coupling by $g_{YM} \sim g_s l_s^{p-3}$. This suggests that is possible to make gauge theory calculations from supergravity solutions and this is indeed one of the motivations of the AdS/CFT correspondence [3]. The original statement of AdS/CFT is that $\mathcal{N} = 4$ super-Yang Mills theory is dual to type IIB strings in $AdS_5 \times S^5$. In fact $SU(\mathcal{N}) = 4$ super-Yang Mills is the field theory on $\mathcal{N}$ D3 branes at low energies, and the near horizon limit of these branes is $AdS_5 \times S^5$. In addition, for the specific value $p = 3$, we have that $g_{YM} \sim g_s$ and one can take the limit $l_s \to 0$ and trust in the supergravity approximation. For $\mathcal{N} = 4$ super-Yang Mills theory the beta function vanish at all orders and is therefore conformally invariant, which means that the coupling constant is not renormalized. This is reflected in the $AdS_5$ factor of conjectured dual. The theory is also scale invariant quantum mechanically. As a consequence of the conformal symmetry the number of supercharges of the super Yang Mills side is 32, the same than IIB superstrings in $AdS_5 \times S^5$. The supergroups of both theories are the same. Besides, both sides contains two parameters. For the Yang-Mills theory they are $g_{YM}$ and $\mathcal{N}$ and for the superstring side they are the string tension $R^2/\alpha$ and $g_s$. In addition to the identification $g_{YM} \sim g_s$ the AdS/CFT conjecture implies that the t Hooft coupling is given by $\lambda = R^4/\alpha^2$.

The gravity description of string theory, which occurs when the size of the graviton is much less than the radius of the space, corresponds to the limit $\lambda >> 1$. In these limit non perturbative phenomena of the super Yang-Mills side can be analyzed. This implies that the AdS/CFT correspondence relates the weak coupling limit of one of the theories to the strong coupling of the other and viceversa, which makes it a powerful tool in order to study
strongly coupled regimes in gauge theories. A precise statement of the correspondence was developed further in \cite{4}, where it was stated that composite operators of the form $O_{i_1...i_k}(x) = Tr(\phi_{i_1}\ldots\phi_{i_k})$ mix and are renormalized, therefore they acquire anomalous dimensions. These dimensions are identified with the energy eigenstates of IIB strings over $AdS_5 \times S^5$.

A more recent advance in understanding AdS/CFT is the BMN correspondence, in which the anomalous dimensions of large R-operators were related to the spectrum of string theory on the pp-wave limit of $AdS_5 \times S^5$ \cite{6}. This idea was refined in \cite{7} by stating that gauge theory operators with large spin are dual to strings rotating in the AdS space. The main observation providing this identification is that, for strings rotating in the AdS space, the difference between the energy and the spin of the configuration depends logarithmically on the spin. This logarithmic dependence is characteristic of the anomalous dimensions of the twist operators of the gauge theory. There is evidence about that the logarithmic dependence does not acquire corrections if we go from the perturbative to the strong coupling regime in the t ’Hooft coupling \cite{8}.

Although $\mathcal{N} = 4$ super-Yang Mills cannot be considered as a realistic theory, the AdS/CFT correspondence could be an useful tool in realistic calculations. This is because the finite temperature version of $\mathcal{N} = 4$ SYM has certain analogies with realistic elementary particle models, although the zero temperature version has not (see for instance \cite{17}). Also, the purely gravitational aspects of this correspondence are related to a wide variety of problems in differential geometry (see for instance \cite{14}). Nevertheless, it is of interest is to generalize this duality to other type of theories. This could be for instance theories with less number of supersymmetries than 32 \cite{15}-\cite{16}, or to consider non conformal field theories duals \cite{5}, such as the Klebanov-Strassler ones \cite{9}. For conformal field theories, the AdS/CFT correspondence has been generalized to the holographic principle \cite{4}, in which is stated that any AdS vacuum of string or M theory define a conformal field theory. In the case of $AdS_5 \times X_5$, being $X_5$ an Einstein manifold, the central charge of the conformal field theory is, in the large $N$ limit, inversely proportional to the volume of $X_5$ \cite{18}. The holographic principle permits to consider gauge/string duals with less number of supersymmetries, and have been generalized for eleven dimensional backgrounds of the form $AdS_4 \times X_7$, which are duals to three dimensional superconformal field theories \cite{4}.

The holographic principle renewed the interest in constructing 5 and 7-dimensional Einstein manifolds and in particular those admitting at least one conformal Killing spinor. The number of such spinors will be related to the number of supersymmetries of the conformal field theory. This leads to consider weak $G_2$ holonomy spaces, Einstein-Sasaki spaces and tri-Sasaki ones. Several examples have been constructed for instance in \cite{31}-\cite{44} and there have been certain success for finding gauge/gravity duals corresponding to these backgrounds \cite{45}-\cite{62}.

A new step for finding gauge/gravity duals with less number of supersymmetries was achieved in \cite{12}, where it was considered a three parameter deformations of $\mathcal{N} = 4$ super-Yang Mills superpotential that preserves $\mathcal{N} = 1$ supersymmetry \cite{13} (see also \cite{11}). These deformations are called $\beta$ deformations. The original superpotential of the theory
\[ W = Tr[[\Phi_1, \Phi_2], \Phi_3] \] is transformed as

\[ Tr(\Phi_1 \Phi_2 \Phi_3 - \Phi_1 \Phi_3 \Phi_2) \to h Tr(e^{i\pi\beta} \Phi_1 \Phi_2 \Phi_3 - e^{-i\pi\beta} \Phi_1 \Phi_3 \Phi_2) + h' Tr(\Phi_1^2 + \Phi_2^2 + \Phi_3^2), \]

(1.1)

being \( h, h', \beta \) complex parameters, satisfying one condition by conformal invariance. One election could be \( h' = 0 \). Besides the \( U(1)_R \) symmetry, there is a \( U(1) \times U(1) \) global symmetry generated by

\[ U(1)_1 : (\Phi_1, \Phi_2, \Phi_3) \to (\Phi_1, e^{i\varphi_1} \Phi_2, e^{-i\varphi_1} \Phi_3), \]

\[ U(1)_2 : (\Phi_1, \Phi_2, \Phi_3) \to (e^{-i\varphi_2} \Phi_1, e^{i\varphi_2} \Phi_2, \Phi_3), \]

(1.2)

which leaves the superpotential and the supercharges invariant. Therefore there is a two dimensional manifold of \( N = 1 \) CFT with a torus symmetry. It was found in [12] that the \( U(1) \times U(1) \) action is realized in gravity part as an isometry. The effect of the \( \gamma \)-deformation of \( N = 4 \) super Yang-Mills induce in the gravity dual the simple transformation

\[ \tau \equiv B + i\sqrt{g} \to \tau \to \tau' = \frac{\tau}{1 + \gamma \tau}, \]

(1.3)

where \( \sqrt{g} \) is the volume of the two torus [12]. The transformation (1.3) indeed comes from a known solution generating technique explained in [10].

The transformations (1.3) are not the full \( SL(2, R) \) transformations. Indeed (1.3) is the subgroup of \( SL(2, R) \) for which \( \tau \to 0 \) implies that \( \tau' \to 0 \). In fact, from (1.3) it follows that \( \tau_\gamma = \tau + o(\tau^2) \) for small \( \tau \). Transformations with these properties are the only possible ones mapping a ten dimensional geometry which is non-singular to a new one also without singularities. The reason is that the only points where a singularity can be introduced by performing an \( SL(2, R) \) transformation is where the two torus shrinks to zero size. This shrink happens when \( \tau' \to 0 \) but for \( \gamma \) transformations, this implies that \( \tau \to 0 \). Therefore, if the original metric was non-singular, then the deformed metric is also non singular [12]. The transformation (1.3) is the result of doing a T-duality on one circle, a change of coordinates, followed by another T-duality. This is another reason for which it can be interpreted as a solution generating technique [10]. It has been applied recently in order to find several deformed backgrounds in [63]-[65], together with an analysis of their gauge field theory duals.

\textit{Sketch of the present work}

In the present work we construct an infinite family of tri-Sasaki metrics in seven dimensions and we find that all these metrics admit an squashed version which is of weak \( G_2 \) holonomy. The idea behind this construction is simple. Our starting point are the Swann hyperKahler metrics [79], which are fibrations over quaternion Kahler metrics \( g_4 \) of the form

\[ g_s = |u|^2 g_4 + |du + \omega u|^2, \]
being $u$ certain quaternion coordinate and $\omega$ an imaginary quaternion valued 1-form associated to the quaternion Kahler space. Under the transformation $u \to \lambda u$ these metrics are scaled by a factor $g_s \to \lambda^2 g_s$, thus are conical and define a family tri-Sasaki metrics. We find the explicit expression for these family, which is composed by fibrations over quaternion Kahler spaces. The six dimensional space formed by the orbits of the Reeb vector is indeed well known, it is the twistor space $Z$ associated to the quaternion Kahler base. The resulting reduced metric is the natural Kahler-Einstein metric defined over $Z$ [22]. This result are presented in the proposition 1 of section 2.

We show that if the quaternion Kahler base is CP(2), the resulting tri-Sasaki metric is $N(1,1)_I$, which is known to admit an squashed version $N(1,1)_{II}$ of weak $G_2$ holonomy [34]. Guided by this result, we find that the squashed version of any of the tri-Sasaki metrics that we are presenting are of weak $G_2$ holonomy. They are indeed the weak $G_2$ holonomy metrics defined by the exactly conical family of Bryant-Salamon Spin(7) metrics [23].

We then manage to find tri-Sasaki (and weak $G_2$ holonomy) examples which are locally $T^3$ fibrations. These 7-dimensional Einstein metrics are fibered over certain quaternion Kahler orbifolds, the quaternion Kahler limit of the euclidean AdS-Kerr-Newman-Taub-Nut metrics. These 4-metrics itself corresponds to a Wick rotation of the Minkowski Plebanski-Demianski metric [81] and were considered in several contexts [82]-[87]. In some limiting cases for the parameters, the euclidean versions tends to $S^4$ or CP(2), which are smooth. We also consider the most general quaternion Kahler $T^2$ fibrations, which were found in [95]. The presence of orbifold singularities is of interest in the context of AdS/CFT correspondence, because they lead to situations generalizing those analyzed by Mandal et all in [76].

We then lift these 7-metrics to supergravity solutions possessing near horizon limit $AdS_4 \times X_7$, being $X_7$ a tri-Sasaki or weak $G_2$ holonomy space. We also construct solutions which does not have this horizon limit. In the manifold limit $S^4$ of the quaternion Kahler base we analyze rotating membrane configurations and we reproduce the logarithmic behaviour of E-S, thus these configurations are dual to the ”twist” operators of the dual conformal field theory.

We also consider the effect of the SL(2,R) deformation and construct new supergravity solutions, the deformed ones. We reproduce the logarithmic behaviour for the deformed background corresponding to $S^4$.

For completeness, we discuss another type of Kahler-Einstein examples that are present in the literature and present some Calabi-Yau metrics fibered over non symmetric Kahler spaces, by using the methods developed in [68], [69].

2. Conical internal spaces

A wide variety of supergravity backgrounds can be constructed as fibrations over Ricci flat conical metrics. An $n$-dimensional manifold $X_n$ develops a conical singularity if and
only if it is possible to find a coordinate system with a coordinate $r$ for which the metric has the local form

$$g_n = dr^2 + r^2 g_{n-1}, \quad (2.4)$$

being $g_{n-1}$ a metric tensor independent on $r$. The metric $g_n$ will be singular at $r = 0$, except if $g_{n-1}$ is the round $n - 1$ dimensional sphere. Any metric $g_n$ of the form (2.4) is called a cone over $g_{n-1}$. There also exist metrics taking the form (2.4) for large values of $r$, such metrics are called asymptotically conical. If the conical metric $g_n$ is Ricci-flat, that is, its Ricci tensor satisfies $R_{ij} = 0$, then $g_{n-1}$ is Einstein, which means that its Ricci tensor is given by $R_{ab} \sim g_{ab}$. In this section we discuss the geometrical properties of such cones and construct a large family. The geometrical objects that enter in this construction are Kahler-Einstein, Einstein-Sasaki, tri-Sasaki, hyperKahler, weak $G_2$ and $Spin(7)$ holonomy spaces. We use the word space instead of manifold in order to keep open the possibility of constructing spaces admitting orbifold or other type of singularities. The reader who is familiar with these concepts can jump to the last two subsections, in particular to the proposition 1.

### 2.1 Spin(7) and weak $G_2$ holonomy

A weak $G_2$ holonomy space $X_7$ is a seven dimensional space with a metric $g_7$ and admitting at least one conformal Killing spinor, that is, a spinor satisfying $D_i \eta \sim \lambda \eta$ [107]. Here $\lambda$ is a constant and $D_i$ is the covariant derivative in spinor representation, which is defined by $D_i = \partial_i + \omega_{iab} \gamma^{ab}$. The one form $\omega_{ab}$ is the spin connection on $X_7$ defined by the first Cartan equation with zero torsion and $\gamma^{ab}$ is the antisymmetric product of Dirac $\gamma^a$ matrices in seven dimensions. If the constant $\lambda$ is zero, then the spinor will be covariantly constant and it will be preserved after parallel transport along any closed curve. This means that the holonomy will be in $G_2$, which is the subgroup of $SO(7)$ which possess a one-dimensional invariant subspace. The reduction of the holonomy to $G_2$ is equivalent to the existence of a $G_2$ invariant three form

$$\Phi = c_{abc} e^a \wedge e^b \wedge e^c$$

which is covariantly constant, that is, $\nabla_X \Phi = 0$ for any vector field $X$. We denote as $e^a$ seven soldering forms for which the metric is diagonal, i.e, $g_7 = \delta_{ab} e^a \otimes e^b$ and $c_{abc}$ are the octonion multiplication constants. This condition holds if and only if $\Phi$ and its dual $\ast \Phi$ are closed. Instead for a weak $G_2$ holonomy space the existence of a conformal Killing vector is equivalent to the condition $d \Phi = \lambda \ast \Phi$. Such spaces have generically $SO(7)$ holonomy and there exist a frame for which the spin connection $\omega_{ab}$ satisfies

$$\omega_{ab} = \frac{c_{abcd}}{2} \omega_{cd} - \lambda c_{abc} e^c,$$

being $c_{abcd}$ the dual octonion constants. The last condition implies that a weak $G_2$ holonomy manifold is always Einstein, i.e, $R_{ij} = \lambda g_{ij}$. In the limit $\lambda \to 0$ the space will be
Ricci flat. This is the case for a $G_2$ holonomy space or for any euclidean space admitting covariantly constant Killing spinors.

By another side, spaces with holonomy in $\text{Spin}(7) \in SO(8)$ are eight dimensional and also admitting one covariantly constant Killing spinor, thus are Ricci flat. Similarly to its $G_2$ counterpart, they are characterized by a closed $\text{Spin}(7)$ invariant four form

$$\Phi_4 = \tilde{c}_{abcd} e^a \wedge e^b \wedge e^c \wedge e^d.$$  

We are in the middle dimension here and $\Phi_4 = *\Phi_4$. Here $\tilde{c}_{abcd}$ are constants related to the octonion constants and from its values it follows that $\Phi_4$ can be reexpressed as

$$\Phi_4 = e^8 \wedge \Phi + *\Phi$$  \hspace{1cm} (2.5)

being $\Phi$ a $G_2$ invariant three-form constructed with the seven remaining soldering forms. The expression (2.5) is the origin of a correspondence between conical $\text{Spin}(7)$ holonomy metrics of cohomogeneity one and weak $G_2$ holonomy ones. More precisely, any of such $\text{Spin}(7)$ metrics is of the form

$$g_8 = dr^2 + r^2 g_7,$$

being $g_7$ a metric of weak $G_2$ holonomy and conversely, for any weak $G_2$ holonomy metric $g_7$ the cone $g_8$ will be of $\text{Spin}(7)$ holonomy. This can be seen as follows. Let us consider the choice of the frame $\tilde{e}^a$ given by

$$\tilde{e}^8 = dr, \quad \tilde{e}^a = -\frac{\lambda}{4} r e^a,$$  \hspace{1cm} (2.6)

being $e^a$ seven soldering forms corresponding to $g_7$. In principle there is an $SO(8)$ freedom to choose our frame, but if the element $\tilde{e}^8$ is fixed as $\tilde{e}^8 = dr$, then there it remains an $SO(7)$ freedom only. The first Cartan structure

$$d\tilde{e}^a + \tilde{\omega}^{ab} \wedge \tilde{e}^b = 0,$$

gives the decomposition

$$\omega^{ab} = \tilde{\omega}^{ab}, \quad \tilde{\omega}^8 = \frac{\lambda}{4} e^a,$$  \hspace{1cm} (2.7)

being $\omega_{ab}$ the spin connection for the seven dimensional part. Let us assume that the form $\tilde{\Phi}$ constructed with (2.6) is closed, this is what we mean about cohomogeneity one. Then (2.6) and (2.5) gives

$$\bar{\Phi} = \left(\frac{\lambda r}{4}\right)^3 dr \wedge \Phi + \left(\frac{\lambda r}{4}\right)^4 *\Phi,$$

$$d\bar{\Phi} = -\left(\frac{\lambda r}{4}\right)^3 dr \wedge (d\Phi - \lambda *\Phi) + \left(\frac{\lambda r}{4}\right)^4 d *\Phi,$$  \hspace{1cm} (2.8)

where $\Phi$ and $*\Phi$ are the usual seven-dimensional 3- and 4-form constructed with the frame $e^a$. It is directly seen from (2.8) that $\text{Spin}(7)$ holonomy condition, namely $d\bar{\Phi} = 0$
is equivalent to weak $G_2$ holonomy of the seven-dimensional base space, that is, to the condition
\[ d\Phi - \lambda \star \Phi = 0, \quad d \star \Phi = 0. \]
The converse of this statement is also true. Indeed, equations (2.6) are equivalent to
\[ \tilde{\omega}^{ab} = \frac{1}{2} c_{abcd} \tilde{\omega}^{cd}, \]
which is the eight-dimensional self-duality condition implying the reduction of the holonomy to a subgroup of $Spin(7)$. This is the one to one correspondence we wanted to show [29] (see also [30]).

For applications to marginal deformations of field theories it is needed to focus on metrics with weak $G_2$ holonomy admitting $T^3$ actions. Examples are the Aloff-Wallach spaces $N(k,l) = SU(3)/U(1)$, which possesses two different metrics $N(k,l)_I$ and $N(k,l)_{II}$. Except for $N(1,1)_I$, which is tri-Sasaki, the remaining metrics are of weak $G_2$ holonomy. For $N(1,1)$ we have the isometry group $SU(3) \times SO(3)$ while for the other cases we have $SU(3) \times U(1)$. Another example is the squashed seven sphere $SO(5) \times SO(3)/SO(3) \times SO(3)$ with isometry group $SO(5) \times SO(3)$. If the manifold is homogeneous, that is, if $X_7$ is of the form $G/H$ then it will be one of this type, see [32]-[33] for a detailed discussion.

Our aim is to construct a more large class of weak $G_2$ holonomy manifolds admitting a $T^3$ action, not necessarily homogeneous.

### 2.2 Einstein-Sasaki and Kahler-Einstein spaces

As in the previous subsection, let us consider an eight dimensional space $X_8$ endowed with a metric $g_8$ and with holonomy in $Spin(7)$. If $X_8$ possess two Killing spinors instead of one, then the holonomy will be reduced further to $SU(4) \in Spin(7)$. In fact, $SU(4)$ is the subgroup of $SO(8)$ with a two dimensional invariant subspace. As is well known, any $2n$-dimensional metric with holonomy $SU(n)$ is Calabi-Yau, an so is $g_8$. If in addition $g_8$ is conical, then the seven dimensional metric $g_7$ over which $g_8$ is fibered will be called Einstein-Sasaki. This metric will possess two conformal Killing spinors. If there is a third Killing spino, we have a further reduction of the holonomy to $Sp(2) \in SU(4)$. Any 4$n$ dimensional space with holonomy in $Sp(n)$ is hyperKahler, in particular $g_8$. In this case $g_7$ will be called tri-Sasaki because it admits three conformal Killing spinors. We can take this notions as definitions, for any value of $n$. Clearly, any tri-Sasaki metric is Einstein-Sassaki and if we are in seven dimensions they will be of weak $G_2$ holonomy. Also any hyperKahler metric is Calabi-Yau, and in $d = 8$ they will be $Spin(7)$ metrics. The converse of these statements are obviously non true.

Any Calabi-Yau space is Ricci flat due to the presence of Killing spinors, and is also Kahler. A Kahler structure over an space $X_{2n}$ is defined by a doublet $(g_{2n}, I)$ composed by an even dimensional metric $g_{2n}$, a $(1,1)$ antisymmetric tensor $I$ such that $I^2 = -I$ which is covariantly constant, that is $\nabla_X I = 0$ being $\nabla$ the Levi-Civita connection and for which the metric is quaternion hermitian (which means that $g_{2n}(IX, IY) = -g_{2n}(X, Y)$ for any
pair of vector fields $X, Y$ of the tangent space at a given point). From the antisymmetry of $I$ it follows that the $(2, 0)$ tensor with components $\Omega(X, Y) = g_{2n}(IX, Y)$ is a two form. The covariance of $I$ implies that $\Omega$ is closed and that $I$ is integrable, that is, its Nijenhuis tensor vanish identically. This implies that $X_{2n}$ is a complex manifold. Sometimes the triplet $(g_{2n}, I, \Omega)$ is identified as the Kahler structure in the literature, but only if the properties stated above are all satisfied.

An Einstein-Sassaki space $X_{2n+1}$ is always odd dimensional and can be constructed as an $R$ or $U(1)$-fibration over a Kahler-Einstein metric. The local form of their metric is

$$g_{2n+1} = (d\tau + A)^2 + g_{2n}, \quad (2.9)$$

being $\Omega = dA$ the Kahler form of the Kahler-Einstein metric $g_{2n}$. The metric $g_{2n}$ is assumed to be $\tau$-independent. The vector $\partial_\tau$ is Killing, and it is called the Reeb vector. If the orbits of this vector are closed and the action is free, then $X_{2n}$ is a manifold and the odd dimensional manifold $X_{2n+1}$ is regular. If the action has finite isotropy groups then $X_{2n}$ is an orbifold. In addition, the Einstein condition $R_{ij} \sim g_{ij} \text{ for } g_{2n}$ has been shown to be equivalent to [70]

$$\rho = \Lambda \Omega \quad (2.10)$$

being $\rho = -i \partial \bar{\partial} \log \det g$ the Ricci form of the metric $g_{2n}$. The scalar curvature of $g_{2n}$ is $2n\Lambda$.

### 2.3 Quaternion Kahler and hyperKahler spaces

A quaternion Kahler space $M$ is an euclidean $4n$ dimensional space with holonomy group $\Gamma$ included into the Lie group $Sp(n) \times Sp(1) \subset SO(4n)$ [25]-[28]. This affirmation is non trivial if $D > 4$, but in $D = 4$ there is the well known isomorphism $Sp(1) \times Sp(1) \simeq SU(2)_L \times SU(2)_R \simeq SO(4)$ and so to state that $\Gamma \subseteq Sp(1) \times Sp(1)$ is equivalent to state that $\Gamma \subseteq SO(4)$. The last condition is trivially satisfied for any oriented space and gives almost no restrictions, therefore the definition of quaternion Kahler spaces should be modified in $d = 4$.

Here we do a brief description of these spaces, more details can be found in the appendix and in the references therein. For any quaternion exists three automorphism $J^i$ ($i = 1 \, , 2, \, 3$) of the tangent space $TM_x$ at a given point $x$ with multiplication rule $J^i \cdot J^j = -\delta_{ij} + \epsilon_{ijk}J^k$. The metric $g_q$ is quaternion hermitian with respect to this automorphism, that is

$$g_q(X, Y) = g(J^iX, J^iY), \quad (2.11)$$

being $X$ and $Y$ arbitrary vector fields. The reduction of the holonomy to $Sp(n) \times Sp(1)$ implies that the $J^i$ satisfy the fundamental relation

$$\nabla_X J^i = \epsilon_{ijk} J^j \omega^k, \quad (2.12)$$

being $\nabla_X$ the Levi-Civita connection of $M$ and $\omega^i$ its $Sp(1)$ part. As a consequence of hermiticity of $g$, the tensor $\bar{\mathcal{J}}_{ab} = (J^i)_{ce} g_{cb}$ is antisymmetric, and the associated 2-form

$$\mathcal{J} = \bar{\mathcal{J}}_{ab} e^a \wedge e^b$$

10
satisfies
\[ dJ^i = \epsilon_{ijk} J^j \wedge \omega^k, \] (2.13)
being \( d \) the usual exterior derivative. Corresponding to the \( Sp(1) \) connection we can define the 2-form
\[ F^i = d\omega^i + \epsilon_{ijk} \omega^j \wedge \omega^k. \]

For any quaternion Kahler manifold it follows that
\[ R^i_\perp = 2n \kappa J^i, \]
\[ F^i = \kappa J^i, \]
being \( \Lambda \) certain constant and \( \kappa \) the scalar curvature. The tensor \( R^i_\perp \) is the \( Sp(1) \) part of the curvature. The last two conditions implies that \( g \) is Einstein with non zero cosmological constant, i.e, \( R_{ij} = 3\kappa(g_q)_{ij} \) being \( R_{ij} \) the Ricci tensor constructed from \( g_q \). The \((0,4)\) and \((2,2)\) tensors
\[ \Theta = J^1 \wedge J^1 + J^2 \wedge J^2 + J^3 \wedge J^3, \]
\[ \Xi = J^1 \otimes J^1 + J^2 \otimes J^2 + J^3 \otimes J^3 \]
are globally defined and covariantly constant with respect to the usual Levi Civita connection for any of these spaces. This implies in particular that any quaternion Kahler space is orientable.

In four dimensions the Kahler triplet \( J_2 \) and the one forms \( \omega^a \) are
\[ \omega^a = \omega^a_0 - \epsilon_{abc} \omega^b, \]
\[ J_1 = e^1 \wedge e^2 - e^3 \wedge e^4, \]
\[ J_2 = e^1 \wedge e^3 - e^2 \wedge e^4 \]
\[ J_3 = e^1 \wedge e^4 - e^2 \wedge e^3. \]
In this dimension quaternion Kahler spaces are defined by the conditions \((1.213)\) and \((1.212)\). This definition is equivalent to state that quaternion Kahler spaces are Einstein and with self-dual Weyl tensor.

In the Ricci-flat limit \( \kappa \to 0 \) the holonomy of a quaternion Kahler space is reduced to a subgroup of \( Sp(n) \) and the resulting spaces are hyperKahler. It follows from \((1.213)\) and \((2.12)\) that the almost complex structures \( J_i \) are covariantly constant in this case. Also, there exist a frame for which \( \omega^i \) goes to zero. In four dimensions this implies that the spin connection corresponding to this frame is self-dual.

### 2.4 An infinite tri-Sasaki family in detail

The results of this section are crucial for the purposes of the present work. For this reason we will make the calculations in detail. As we have stated, any hyperKahler conical metric \( g_8 \) define a tri-Sasaki metric by means of the formula \( g_8 = dr^2 + r^2 g_7 \). A well known family of conical hyperKahler metrics are the Swann metrics \([79]\), this are \( 4n \) dimensional metrics but we will focus only in the case \( d = 8 \). The metrics reads
\[ g_8 = |u|^2 g_q + |du + u\omega_\perp|^2, \] (2.16)
being $g_q$ any 4-dimensional quaternion Kahler metric. In the expression for the metric we have defined the quaternions

$$u = u_0 + u_1 I + u_2 J + u_3 K, \quad \overline{u} = u_0 - u_1 I - u_2 J - u_3 K,$$

and the quaternion one form

$$\omega_- = \omega_1^i I + \omega_2^i J + \omega_3^i K,$$

constructed with the anti-self-dual spin connection. The multiplication rule for the quaternions $I$, $J$ and $K$ is deduced from

$$I^2 = J^2 = K^2 = -1, \quad IJ = K, \quad JK = -I.$$

The metric $g_q$ is assumed to be independent on the coordinates $u_i$. We easily see that if we scale $u_0$, $u_1, u_2, u_3$ by $t > 0$ this scales the metric by a homothety $t$, which means that the metrics (2.16) are conical. Therefore they define a family of tri-Sasaki metrics, which we will find now. We first obtain, by defining $\tilde{u}_i = u_i/u$ that

$$|du + u\omega_-|^2 = (du_0 - u_i\omega_+^i)^2 + (du_i + u_0\omega_+^i + \frac{\epsilon_{ijk}}{2}u_k\omega_+^j)^2$$

$$= (\tilde{u}_0 du + u\tilde{u}_0 - u\tilde{u}_i\omega_+^i)^2 + (\tilde{u}_i du + u\tilde{u}_i + u\tilde{u}_0\omega_+^i + u\frac{\epsilon_{ijk}}{2}\tilde{u}_k\omega_+^j)^2$$

$$= du^2 + u^2(d\tilde{u}_0 - \tilde{u}_i\omega_+^i)^2 + u^2(d\tilde{u}_i + \tilde{u}_0\omega_+^i + \frac{\epsilon_{ijk}}{2}\tilde{u}_k\omega_+^j)^2$$

$$+ 2u\tilde{u}_0 du(d\tilde{u}_0 - \tilde{u}_i\omega_+^i) + 2u\tilde{u}_i du(d\tilde{u}_i + \tilde{u}_0\omega_+^i + \frac{\epsilon_{ijk}}{2}\tilde{u}_k\omega_+^j).$$

It is not difficult to see that the last two terms are equal to

$$2u\tilde{u}_0 du(d\tilde{u}_0 - \tilde{u}_i\omega_+^i) + 2u\tilde{u}_i du(d\tilde{u}_i + \tilde{u}_0\omega_+^i + \epsilon_{ijk}\tilde{u}_j\tilde{u}_k\omega_+^j) = \frac{d(\tilde{u}_0^2)}{2} + \frac{\epsilon_{ijk}}{2}\tilde{u}_i\tilde{u}_j\omega_+^k.$$

But the second term is product of a antisymmetric pseudotensor with a symmetric expression, thus is zero, and the first term is zero due to the constraint $\tilde{u}_i^2 = 1$. Therefore this calculation shows that

$$|du + u\omega_-|^2 = du^2 + u^2(d\tilde{u}_0 - \tilde{u}_i\omega_+^i)^2 + u^2(d\tilde{u}_i + \tilde{u}_0\omega_+^i + \frac{\epsilon_{ijk}}{2}\tilde{u}_k\omega_+^j)^2. \quad (2.17)$$

By introducing (2.17) into (2.16) we find that $g_q$ is a cone over the following metric

$$g_7 = g_q + (d\tilde{u}_0 - \tilde{u}_i\omega_+^i)^2 + (d\tilde{u}_i + \tilde{u}_0\omega_+^i + \frac{\epsilon_{ijk}}{2}\tilde{u}_k\omega_+^j)^2. \quad (2.18)$$

This is the tri-Sasaki metric we were looking for. By expanding the squares appearing in (2.18) we find that

$$g_7 = g_q + (d\tilde{u}_0)^2 + (\omega_+^i)^2 + 2(\tilde{u}_0d\tilde{u}_1 - \tilde{u}_1d\tilde{u}_0 + \tilde{u}_2d\tilde{u}_3 - \tilde{u}_3d\tilde{u}_2)$$
+ 2\omega^2 (\tilde{u}_0 d\tilde{u}_2 - \tilde{u}_2 d\tilde{u}_0 + \tilde{u}_2 d\tilde{u}_1 - \tilde{u}_1 d\tilde{u}_2) + 2\omega_3^2 (\tilde{u}_0 d\tilde{u}_3 - \tilde{u}_3 d\tilde{u}_0 + \tilde{u}_1 d\tilde{u}_2 - \tilde{u}_2 d\tilde{u}_1). \quad (2.19)

But the expression in parenthesis are a representation of the SU(2) Maurer-Cartan 1-forms, which are defined by

\[ \sigma_1 = -(\tilde{u}_0 d\tilde{u}_1 - \tilde{u}_1 d\tilde{u}_0 + \tilde{u}_2 d\tilde{u}_3 - \tilde{u}_3 d\tilde{u}_2) \]
\[ \sigma_2 = -(\tilde{u}_0 d\tilde{u}_2 - \tilde{u}_2 d\tilde{u}_0 + \tilde{u}_2 d\tilde{u}_1 - \tilde{u}_1 d\tilde{u}_3) \]
\[ \sigma_3 = -(\tilde{u}_0 d\tilde{u}_3 - \tilde{u}_3 d\tilde{u}_0 + \tilde{u}_1 d\tilde{u}_2 - \tilde{u}_2 d\tilde{u}_1). \]

Therefore the metric (2.18) can be reexpressed in simple fashion as

\[ g_7 = g_q + (\sigma_i - \omega^i)^2. \quad (2.20) \]

This is one of the expressions that we will use along this work.

Let us recall that there exist a coordinate system for which the Maurer-Cartan forms are expressed as

\[ \sigma_1 = \cos \varphi d\theta + \sin \varphi \sin \theta d\tau, \quad \sigma_2 = -\sin \varphi d\theta + \cos \varphi \sin \theta d\tau, \quad \sigma_3 = d\varphi + \cos \theta d\tau. \quad (2.21) \]

With the help of this coordinates we will write (2.20) in more customary form for tri-Sasaki spaces, namely

\[ g_7 = (d\tau + H)^2 + g_6, \quad (2.22) \]

as in (2.9). Here \( g_6 \) a Kahler-Einstein metric with Kahler form \( \mathcal{J} \) and \( H \) a 1-form such that \( dH = 2\mathcal{J} \). A lengthy algebraic calculation shows that the fiber metric is

\[ (\sigma_i - \omega^i)^2 = (d\tau + \cos \theta d\varphi - \sin \theta \sin \varphi \omega_1^1 - \cos \theta \sin \varphi \omega_2^2 - \cos \theta \omega_3^3)^2 \]
\[ + (\sin \theta d\varphi - \cos \theta \sin \varphi \omega_1^1 - \cos \theta \cos \varphi \omega_2^2 + \sin \theta \omega_3^3)^2 + (d\theta - \sin \varphi \omega_2^2 + \cos \varphi \omega_3^3)^2, \]

from where we read that

\[ H = \cos \theta d\varphi - \sin \theta \sin \varphi \omega_1^1 - \cos \theta \sin \varphi \omega_2^2 - \cos \theta \omega_3^3. \quad (2.23) \]

The vector \( \partial_\tau \) is the Reeb vector, and is a Killing vector. The six dimensional metric

\[ g_6 = g_q + (d\theta - \sin \varphi \omega_2^2 + \cos \varphi \omega_3^3)^2, \quad (2.24) \]
\[ + (\sin \theta d\varphi - \cos \theta \sin \varphi \omega_1^1 - \cos \theta \cos \varphi \omega_2^2 + \sin \theta \omega_3^3)^2, \]

should be Kahler-Einstein. We will check that this is the case next.

**Another deduction of the tri-Sasaki metrics (2.20)**

We will prove now that the six dimensional space formed by the orbits of the Reeb vector of the tri-Sasaki family presented above is the twistor space \( Z \) associated to the quaternion Kahler base. The resulting reduced metric (2.24) is the natural Kahler-Einstein
metric defined over Z \[22\]. We need first to define what is \(Z\). Recall that for any quaternion Kahler space \(M\), a linear combination of the almost complex structures of the form \(J = \tilde{v}_i J_i\) will be also an almost complex structure on \(M\). Here \(\tilde{v}^i\) denote three "scalar fields" \(\tilde{v}^i = v^i / v\) being \(v = \sqrt{v^i v^i}\). This fields are assumed to be constant over \(M\) and are obviously constrained by \(\tilde{v}^i \tilde{v}^i = 1\). This means that the bundle of almost complex structures over \(M\) is parameterized by points on the two sphere \(S^2\). This bundle is what is known as the twistor space \(Z\) of \(M\). The space \(Z\) is endowed with the metric

\[g_6 = \theta_1 \theta_1 + g_\bullet,\]  

(2.25)

where \(\theta_i = d(\tilde{v}^i) + \epsilon^{ijk} \omega^j_\perp \tilde{v}^k\). The constraint \(\tilde{v}^i \tilde{v}^i = 1\) implies that the metric (2.25) is six dimensional. It have been shown that this metric together with the sympletic two form \[J = -\tilde{u}_i \tilde{J}_i + \frac{\epsilon^{ijk}}{2} v_i \theta_j \land \theta_k,\]  

(2.26)

constitute a Kahler structure. The calculation of the Ricci tensor of \(g_6\) shows that it is also Einstein, therefore the space \(Z\) is Kahler-Einstein. The expressions given below are written for a quaternion Kahler metric normalized such that \(\kappa = 1\), for other normalizations certain coefficients must be included in (2.26). By parameterizing the coordinates \(\tilde{v}_i\) in the spherical form

\[\tilde{v}_1 = \sin \theta \sin \varphi, \quad \tilde{v}_2 = \sin \theta \cos \varphi, \quad \tilde{v}_3 = \cos \theta,\]  

(2.27)

we find that (2.25) is the same as (2.24). The isometry group of the Kahler-Einstein metrics is in general \(SO(3) \times G\), being \(G\) the isometry group of the quaternion Kahler basis which also preserve the forms \(\omega^j_\perp\). The \(SO(3)\) part is the one which preserve the condition \(\tilde{v}_i \tilde{v}_i = 1\). Globally the isometry group could be larger.

From the definition of Einstein-Sasaki geometry, it follows directly that the seven dimensional metric

\[g_7 = (d\tau + H)^2 + g_6 = (d\tau + H)^2 + \theta_1 \theta_1 + g_\bullet,\]  

(2.28)

will be Einstein-Sasakii if \(dH = 2\tilde{J}\), and we need to find an explicit expression for such \(H\). Our aim is to show that this form is indeed (2.23). The expression (2.26) needs to be simplified as follows. We have that \(\theta_i = d(\tilde{v}^i) + \epsilon^{ijk} \omega^j_\perp \tilde{v}^k\). Also by using the condition \(\tilde{v}_i \tilde{v}_i = 1\) it is found that

\[\tilde{v}_i \theta_i = \tilde{v}_i d\tilde{v}_i + \epsilon^{ijk} \tilde{v}_i \omega^j_\perp \tilde{v}^k = \tilde{v}_i d\tilde{v}_i = d(\tilde{v}_i \tilde{v}_i) = 0.\]

From the last equality it follows the orthogonality condition \(\tilde{v}_i \theta_i = 0\) which is equivalent to

\[\theta_3 = -\frac{(\tilde{v}_1 \theta_1 + \tilde{v}_2 \theta_2)}{\tilde{v}_3}.\]

The last relation implies that

\[\frac{\epsilon^{ijk}}{2} \tilde{v}_i \theta_j \land \theta_k = \frac{\theta_1 \land \theta_2}{\tilde{v}_3} = \frac{d\tilde{v}_1 \land d\tilde{v}_2}{\tilde{v}_3} - d\tilde{v}_i \land \omega^j_\perp + \frac{\epsilon^{ijk}}{2} \tilde{v}_i \omega^j_\perp \land \omega^k_\perp.\]
By another side in a quaternion Kahler manifold with $\kappa = 1$ we always have

$$\tilde{J}_i = d\omega^i - \frac{\epsilon^{ijk}}{2} \omega^j \wedge \omega^k.$$  

Inserting the last two expressions into (2.26) gives a remarkably simple expression for $\tilde{J}$, namely

$$\tilde{J} = -d(\tilde{v}_i \omega^i) + \frac{d\tilde{v}_1 \wedge d\tilde{v}_2}{\tilde{v}_3}. \quad (2.29)$$

By using (2.27) it is obtained that

$$\frac{d\tilde{v}_1 \wedge d\tilde{v}_2}{\tilde{v}_3} = -d\varphi \wedge d\cos \theta.$$  

With the help of the last expression we find that (2.29) can be rewritten as

$$\tilde{J} = -d(\tilde{v}_i \omega^i) - d\varphi \wedge d\cos \theta,$$

from where it is obtained directly that the form $H$ such that $dH = \tilde{J}$ is

$$H = -\tilde{v}_i \omega^i + \cos \theta d\varphi, \quad (2.30)$$

up to a total differential term. By introducing (2.27) into (2.30) we find that $H$ is the same than (2.23), as we wanted to show.

It will be of importance for the purposes of the present work to state these results in a concise proposition.

**Proposition** Let $g_q$ be a four dimensional Einstein space with self-dual Weyl tensor, i.e., a quaternion Kahler space. We assume the normalization $\kappa = 1$ for $g_q$. Then the metrics

$$g_6 = g_q + (d\theta - \sin \varphi \omega^2 + \cos \varphi \omega^1)^2$$

$$+ (\sin \theta d\varphi - \cos \theta \sin \varphi \omega^1 - \cos \theta \cos \varphi \omega^2 + \sin \theta \omega^3)^2$$

are Kahler-Einstein whilst

$$g_7 = (\sigma - \omega^1)^2 + g_q, \quad g_8 = dr^2 + r^2 g_7$$

are tri-Sasaki and hyperKahler respectively. Here $\omega^1$ is the $Sp(1)$ part of the spin connection and $\sigma$ are the usual Maurer-Cartan one forms over $SO(3)$. Moreover the "squashed" family

$$g_7 = (\sigma - \omega^1)^2 + 5g_q,$$

is of weak $G_2$ holonomy.

We will consider the last sentence of this proposition in the next section. In order to finish this section we would like to describe a little more the Swann bundles. Under
the transformation \( u \to Gu \) with \( G : M \to SU(2) \) the \( SU(2) \) instanton \( \omega_- \) is gauge transformed as \( \omega_- \to G\omega_-G^{-1} + GdG^{-1} \). Therefore the form \( du + \omega_- u \) is transformed as

\[
du + u\omega_- \to d(Gu) + (G\omega_-G^{-1} + GdG^{-1})Gu = Gdu + (dG + G\omega_- dG)u = G(du + u\omega_-),
\]

and it is seen that \( du + \omega_- u \) is a well defined quaternion-valued one form over the chiral bundle. The metric (2.16) is also well defined over this bundle. Associated to the metric (2.16) there is a quaternion valued two form

\[
\tilde{J} = uJ\bar{u} + (du + u\omega_-) \wedge (du + u\omega_-),
\]

and it can be checked that the metric (2.32) is hermitian with respect to any of the components of (2.31). Also

\[
\tilde{d}\tilde{J} = du \wedge (J + d\omega_- - \omega_- \wedge \omega_-)\bar{u} + u \wedge (J + d\omega_- - \omega_- \wedge \omega_-)d\bar{u}
+ u(d\tilde{J} + \omega_- \wedge d\omega_- - d\omega_- \wedge \omega_-)\bar{u}.
\]

The first two terms of the last expression are zero due to (1.213). Also by introducing (1.213) into the relation (2.13) it is seen that

\[
d\tilde{J} + \omega_- \wedge d\omega_- - d\omega_- \wedge \omega_- = 0,
\]

and therefore the third term is also zero. This means that the metric (2.16) is hyperKahler with respect to the triplet \( \tilde{J} \). The Swann metrics have been considered in several context in physics, as for instance in [109]-[112]. It is an important tool also in differential geometry because the quaternion Kahler quotient construction correspond to hyperKahler quotients on the Swann fibrations.

### 2.5 A weak \( G_2 \) holonomy family by squashing

In [23] there were probably constructed the first examples of \( Spin(7) \) holonomy metrics. These examples are fibered over four dimensional quaternion Kahler metrics defined over manifold \( M \). This resembles the Swann metrics that we have presented in (2.16), although the Bryant-Salamon were found first. The anzatz for the \( Spin(7) \) is

\[
g_8 = g|u|^2\bar{g} + f|du + u\omega_-|^2,
\]

where \( f \) and \( g \) are two unknown functions \( f(r^2) \) and \( g(r^2) \) which will be determined by the requirement that the holonomy is in \( Spin(7) \), i.e, the closure of the associated 4-form \( \Phi_4 \). The analogy between the anzatz (2.32) and (2.16) is clear, in fact, if \( f = g = 1 \) the holonomy will be reduced to \( Sp(2) \). A convenient (but not unique) choice for \( \Phi_4 \) is the following

\[
\hat{\Phi} = 3fg[\alpha \wedge \bar{\alpha} \wedge \bar{e} \wedge e + e \wedge \alpha \wedge \bar{\alpha} + g^2\bar{e} \wedge e \wedge \bar{e} \wedge e + f^2\alpha \wedge \bar{\alpha} \wedge \alpha \wedge \bar{\alpha}]
\]

(2.33)
where $\alpha = du + u\omega_\perp$. After imposing the condition $d\Phi_4 = 0$ to (2.32) it is obtained a system of differential equations for $f$ and $g$ with solution

$$f = \frac{1}{(2Kr^2 + c)^{2/5}},$$

$$g = (2Kr^2 + c)^{3/5},$$

and the corresponding metric

$$g_s = (2Kr^2 + c)^{3/5}g + \frac{1}{(2Kr^2 + c)^{2/5}}|\alpha|^2. \quad (2.34)$$

Spaces defined by (2.34) are the Bryant-Salamon Spin(7) ones. The metrics (2.34) are non compact (because $|u|$ is not bounded), and asymptotically conical. They will be exactly conical only if $c = 0$. This is better seen by introducing spherical coordinates for $u$

$$u_1 = |u| \sin \theta \cos \varphi \cos \tau,$$

$$u_2 = |u| \sin \theta \cos \varphi \sin \tau,$$

$$u_3 = |u| \sin \theta \sin \varphi,$$

$$u_4 = |u| \cos \theta,$$

and defining the radial variable

$$r^2 = \frac{9}{20}(2|u|^2 + c)^{3/5}$$

from which we obtain the spherical form of the metric

$$g = \frac{dr^2}{\kappa(1 - c/r^{10/3})} + \frac{9}{100 \kappa}r^2 \left(1 - \frac{c}{r^{10/3}}\right)\left(\sigma^i - \omega^i_\perp\right)^2 + \frac{9}{20}r^2 \gamma \quad (2.35)$$

being $\sigma^i$ the left-invariant one-forms on $SU(2)$

$$\sigma_1 = \cos \varphi d\theta + \sin \varphi \sin \theta d\tau$$

$$\sigma_2 = -\sin \varphi d\theta + \cos \varphi \sin \theta d\tau$$

$$\sigma_3 = d\varphi + \cos \theta d\tau.$$

In this case it is clearly seen that (2.35) are of cohomogeneity one and thus, by the results presented on the previous section, they define a weak $G_2$ holonomy metric.

Let us fix the normalization $\kappa = 1$, as before. Then in the limit $r >> c$ it is found the behavior

$$g \approx dr^2 + r^2 \Omega, \quad (2.36)$$
being $\Omega$ a seven dimensional metric asymptotically independent of the coordinate $r$, namely

$$\Omega = (\sigma^i - \omega^i)^2 + 5g_q \quad (2.37)$$

In particular the subfamilies of (2.35) with $c = 0$ are exactly conical and their angular part is (2.37). The metrics (2.37) are of weak $G_2$ holonomy and possesses an $SO(3)$ isometry action associated with the $\sigma^i$. If also the four dimensional quaternion Kahler metric has an isometry group $G$ that preserve the $\omega^i$, then the group is enlarged to $SO(3) \times G$.

### 2.6 An instructive test: the case $N(1,1)_I$ and $N(1,1)_II$

It is important to compare the weak $G_2$ holonomy metrics (2.37) and the tri-Sasaki metrics (2.20). The only difference between the two metrics is a factor 5 in front of $g_q$ in (2.37). Both metrics possess the same isometry group. At first sight it sounds possible to absorb this factor 5 by a simple rescale of the coordinates and therefore to conclude that both metrics are the same. But this is not true. We are fixing the normalization $\kappa = 1$ in both cases, thus this factor should be absorbed only by an rescaling on the coordinates of the fiber. There is no such rescaling. Therefore, due to this factor 5, both metrics are different. This is what one expected, since they are metrics of different type.

We can give an instructive example to understand why this is so. Let us consider the Fubini-Study metric on CP(2). This metric is Kahler-Einstein and quaternion Kahler simultaneously and there exists a coordinate system for it takes the form

$$g_f = 2d\mu^2 + \frac{1}{2} \sin^2 \mu \bar{\sigma}_3^2 + \frac{1}{2} \sin^2 \mu \cos^2 \mu (\bar{\sigma}_1^2 + \bar{\sigma}_2^2). \quad (2.38)$$

We have denoted the Maurer-Cartan one-forms of this expression as $\bar{\sigma}_i$ in order to not confuse them with the $\sigma_i$ appearing in (2.37) and (2.20). The anti-self-dual part of the spin connection is

$$\omega_1 = -\cos \mu \bar{\sigma}_1, \quad \omega_2 = \cos \mu \bar{\sigma}_2, \quad \omega_3 = -\frac{1}{2}(1 + \cos \mu)\bar{\sigma}_3. \quad (2.39)$$

The two metrics that we obtain by use of (2.37) and (2.20) are

$$g_7 = 2b \, d\mu^2 + \frac{1}{2} \sin^2 \mu \bar{\sigma}_3^2 + b \frac{1}{2} \sin^2 \mu \cos^2 \mu (\bar{\sigma}_1^2 + b \bar{\sigma}_2^2) \quad (2.40)$$

$$+ (\sigma_1 + \cos \mu \bar{\sigma}_1)^2 + (\sigma_2 - \cos \mu \bar{\sigma}_2)^2 + (\sigma_3 + \frac{1}{2}(1 + \cos \mu)\bar{\sigma}_3)^2.$$

If (2.37) and (2.20) are correct, then $b = 1$ corresponds to a tri-Sasaki metric and $b = 5$ to a weak $G_2$ holonomy one. This is true. Locally this metrics are the same that $N(1,1)_I$ and $N(1,1)_{II}$ given in [34], which are known to be tri-Sasaki and weak $G_2$. We see therefore that this number five in front of the quaternion Kahler metric is relevant and change topological properties of the metric (such as the number of conformal Killing spinors).
3. Examples of quaternion Kahler manifolds and orbifolds

The tri-Sasaki and weak $G_2$ holonomy spaces presented in proposition 1 are fibered over quaternion Kahler spaces in four dimensions. Such spaces can be extended to a wide variety of supergravity solutions. We are interested in supergravity solutions with three commuting Killing vectors. In this case the SL(2,R) deformation technique described in [12] can be applied, which in many cases correspond to marginal deformations of the field theory duals. The Reeb vector is clearly one of the isometries, and by inspection of the formulas of Proposition 1 it is seen that three commuting Killing vectors will be obtained if the quaternion Kahler base possess two commuting isometries which also preserve the 1-forms $\omega^i$. We will refer to these spaces as toric quaternion Kahler spaces. In this section we describe a large class of such spaces.

3.1 Quaternion Kahler limit of AdS-Kerr-Newman-Taub-Nut

The spaces that we will present next are obtained by a Wick rotation of the Plebanski and Demianski solution [81] and have been discussed in detail in [82]-[87]. After taking certain scaling limit of the parameters, the distance element becomes

\[
g_q = \frac{x^2 - y^2}{P} dx^2 + \frac{x^2 - y^2}{Q} dy^2 + \frac{P}{x^2 - y^2} (d\alpha + y^2 d\beta)^2 + \frac{Q}{x^2 - y^2} (d\alpha + x^2 d\beta)^2 \tag{3.41}
\]

being $P(x)$ and $Q(y)$ polynomials of the form

\[
P(x) = q - 2sx - tx^2 - \kappa x^4, \quad Q(y) = -P(y), \tag{3.42}
\]

being $(q, s, t, \kappa)$ four parameters. These expressions can be rewritten as

\[
P(x) = -\kappa(x - r_1)(x - r_2)(x - r_3)(x - r_4), \quad Q(y) = -P(y),
\]

\[
r_1 + r_2 + r_3 + r_4 = 0,
\]

the last condition comes from the fact that $P(x)$ contains no cubic powers of $x$. The two commuting Killing vectors are $\partial_\alpha$ and $\partial_\beta$.

The metric (3.41) is invariant under the transformation $x \leftrightarrow y$. The transformations $x \to -x$, $y \to -y$, $r_i \to -r_i$ are also a symmetry of the metric. In addition the symmetry $(x, y, \alpha, \beta) \to (\lambda x, \lambda y, \frac{\alpha}{\lambda}, \frac{\beta}{\lambda})$, $r_i \to \lambda r_i$ can be used in order to put one parameter equal to one, so there are only three effective parameters here. The domains of definition are determined by

\[
(x^2 - y^2)P(x) \geq 0, \quad (x^2 - y^2)Q(y) \geq 0.
\]

The anti-self-dual part of the spin connection is

\[
\omega^1 = \frac{\sqrt{PQ}}{y - x} d\beta, \quad \omega^3 = \frac{1}{x - y} \left( \sqrt{\frac{Q}{P}} dx + \sqrt{\frac{P}{Q}} dy \right),
\]

19
\[ \omega^2 = -\kappa(x-y)d\alpha + \frac{1}{x-y} \left( q - s(x+y) - txy - \kappa xy^2 \right) d\beta, \]  \hspace{1cm} (3.43)

(see for instance [85]). We will need (3.43) in the following.

The metrics (3.44) are the self-dual limit of the AdS-Kerr-Newmann-Taub-Nut solutions, the last ones corresponds to the polynomials

\[ P(x) = q - 2sx - tx^2 - \kappa x^4, \quad Q(y) = -q + 2s'x + tx^2 + \kappa x^4, \]

and are always Einstein. But the self-duality condition holds if and only if \( s' = s \), as in (3.42). We will concern with this limit in the following, because is the one which is quaternion Kahler. If we define the new coordinates

\[ y = \tilde{r}, \quad x = a \cos \tilde{\theta} + N, \]
\[ \alpha = t + \left( \frac{N^2}{a} + a \right) \frac{\tilde{\phi}}{\Xi}, \quad \beta = -\frac{\tilde{\phi}}{a\Xi}, \]

where we have introduced the parameters

\[ \Xi = 1 - \kappa a^2, \quad q = - a^2 + N^2(1 - 3\kappa a^2 + 3\kappa N^2), \]
\[ s = N(1 - \kappa a^2 + 4N^2), \quad t = -1 - \kappa a^2 - 6\kappa N^2, \]

then the functions \( P \) and \( Q \) are expressed as

\[ P = - a^2 \sin^2 \tilde{\theta} [1 - \kappa(4aN \cos \tilde{\theta} + a^2 \cos^2 \tilde{\theta})], \]
\[ Q = -\tilde{r}^2 - N^2 + 2s'\tilde{r} + a^2 + \kappa(\tilde{r}^4 - a^2\tilde{r}^2 - 6\tilde{r}^2N^2 + 3a^2N^2 - 3N^4), \]

and the metric take the AdS-Kerr-Newman-Taub-Nut form

\[ g_\eta = \frac{\sin^2 \tilde{\theta} [1 - \kappa(a^2 \cos^2 \tilde{\theta} + 4aN \cos \tilde{\theta})]}{R^2} \left[ d\tilde{t} - \frac{\tilde{r}^2 - a^2 - N^2}{\Xi} d\tilde{\phi} \right]^2 + \frac{\lambda^2}{R^2} \left[ d\tilde{r} + \left( \frac{\sin^2 \tilde{\theta}}{\Xi} - \frac{2N \cos \tilde{\theta}}{\Xi} \right) d\tilde{\phi} \right]^2 + \frac{R^2}{1 - \kappa(a^2 \cos^2 \tilde{\theta} + 4aN \cos \tilde{\theta})} d\tilde{\theta}^2 + \frac{R^2}{\lambda^2} d\tilde{r}^2, \]  \hspace{1cm} (3.44)

being \( R \) and \( \lambda \) defined by

\[ R = \tilde{r}^2 - (a \cos \tilde{\theta} + N)^2, \]
\[ \lambda = \tilde{r}^2 + N^2 - 2s'\tilde{r} - a^2 - \kappa(\tilde{r}^4 - a^2\tilde{r}^2 - 6\tilde{r}^2N^2 + 3a^2N^2 - 3N^4). \]

Notice that the self-dual limit corresponds to the choice \( s' = N(1 - \kappa a^2 + 4aN^2) \) in all the expressions. The parameter \( \kappa \) is the scalar curvature of the metric and we fix \( \kappa = 1 \), as we did previously.

These metrics have interesting limits. For \( a = 0 \) and \( N \) different from zero becomes the AdS Taub-Nut solution with local metric

\[ g_\eta = V(\tilde{r})(d\tilde{t} - 2N \cos \tilde{\theta} d\tilde{\phi})^2 + \frac{d\tilde{r}^2}{V(\tilde{r})} + (\tilde{r}^2 - N^2)(d\tilde{\theta}^2 + \sin^2 \tilde{\theta} d\tilde{\phi}^2), \]  \hspace{1cm} (3.45)
being \( V(\tilde{r}) \) given by

\[
V(\tilde{r}) = \frac{\lambda}{R^2} = \frac{1}{\tilde{r}^2 - N^2} \left( \tilde{r}^2 + N^2 - (\tilde{r}^4 - 6N^2\tilde{r}^2 - 3N^4) - 2s'\tilde{r} \right).
\]

This metric has been considered in different contexts [82]-[87]. The parameter \( s' \) is a mass parameter and \( N \) is a nut charge. Both parameters are not independent in the quaternion Kahler limit, in fact the self-duality condition \( s' = s \) relates them as \( s' = N(1 + 4N^2) \). If the mass were arbitrary then the metric will possess a "bolt", but in this case the metric will possess a "nut", that is, a zero dimensional regular fixed point set. The isometry group of (3.43) is enhanced from \( U(1) \times U(1) \) to \( SU(2) \times U(1) \) in this limit. The anti self-dual part of the spin connection reads

\[
\omega_+^1 = -\sqrt{(\tilde{r} + N)V(\tilde{r})}\sin\theta d\tilde{\phi}, \quad \omega_+^2 = \sqrt{(\tilde{r} + N)V(\tilde{r})}d\tilde{\theta},
\]

\[
\omega_-^2 = (\tilde{r} - N)d\tilde{t} + g(\tilde{r})\cos\tilde{\theta}d\tilde{\phi}, \quad \omega_-^3 = (\tilde{r} - N)d\tilde{t} + g(\tilde{r})\cos\tilde{\theta}d\tilde{\phi}, \quad (3.46)
\]

being \( g(\tilde{r}) \) defined by

\[
g(\tilde{r}) = \left( \frac{N^2(\tilde{r} - N) + N(1 + 4N^2) + (1 + 6N^2)\tilde{r} - 2N\tilde{r}^2}{\tilde{r} - N} \right).
\]

By taking the further limit \( N = 0 \), that is, but switching off the mass and the charge, we obtain after introducing the new radius \( \tilde{r} = \sin \tilde{\rho} \) the following distance element

\[
g_q = \cos^2 \tilde{\rho}d\tilde{t}^2 + d\tilde{\rho}^2 + \sin^2 \tilde{\rho}(d\tilde{\theta}^2 + \sin^2 \tilde{\theta}d\tilde{\phi}^2).
\]

The anti-self-dual spin connection takes the simple form

\[
\omega_+^1 = \cos \tilde{\rho} \sin \tilde{\theta} d\tilde{\phi}, \quad \omega_+^2 = \sin \tilde{\rho} d\tilde{t} + \cos \tilde{\theta} d\tilde{\phi}, \quad \omega_-^3 = \cos \tilde{\rho} d\tilde{\theta},
\]

and it follows that we have obtained the metric of the sphere \( S^4 = SO(5)/SO(4) \). If we would choose negative scalar curvature instead, this limit would correspond to the non compact space \( SO(4,1)/SO(4) \). Both cases are maximally symmetric and for this reason this is called the \( AdS_4 \) limit of the \( AdS\)-Taub-Nut solution.

The other 4-dimensional quaternion Kahler manifold is CP(2) with the Fubbini-Study metric. This case is obtained by defining the new coordinates \( \tilde{r} = N(\tilde{r} - N) \) and \( \tilde{t} = 2N\tilde{\xi} \) and taking the limit \( N \rightarrow \infty \). The result, after defining \( \tilde{\rho} = \tilde{r}^2/4(1 + \tilde{r}^2) \), is the metric

\[
g_q = \frac{\tilde{\rho}^2}{2(1 + \tilde{\rho}^2)^2}(d\xi - \cos \tilde{\theta} d\tilde{\phi})^2 + \frac{2d\tilde{\rho}^2}{(1 + \tilde{\rho}^2)^2} + \frac{\tilde{\rho}^2}{2(1 + \tilde{\rho}^2)^2}(d\tilde{\theta}^2 + \sin^2 \tilde{\theta}d\tilde{\phi}^2). \quad (3.47)
\]

By noticing that \( \sigma_3 = d\xi - \cos \tilde{\theta} d\tilde{\phi} \) and that \( \sigma_1^2 + \sigma_3^2 = d\tilde{\theta}^2 + \sin^2 \tilde{\theta}d\tilde{\phi}^2 \) we recognize from (3.47) the Bianchi IX form for the Fubbini-Study metric on CP(2)=SU(3)/SU(2).

Another possible limit of (3.48) is \( N \rightarrow 0 \), the result will be the AdS-Kerr euclidean solution, namely

\[
g_q = \frac{\sin^2 \tilde{\theta}(1 - a^2 \cos^2 \tilde{\theta})}{\tilde{r}^2 - a^2 \cos^2 \tilde{\theta}}(d\tilde{t} - \tilde{r}^2 - a^2 \Xi d\tilde{\phi})^2 \quad (3.48)
\]
\[ + \frac{\tilde{r}^2 - a^2 \cos \tilde{\theta}^2}{1 - a^2 \cos^2 \tilde{\theta}} d\tilde{\theta}^2 + \frac{\tilde{r}^2 - a^2 \cos \tilde{\theta}^2}{(\tilde{r}^2 - a^2)(1 - \tilde{r}^2)} d\tilde{r}^2 + \frac{(\tilde{r}^2 - a^2)(1 - \tilde{r}^2)}{\tilde{r}^2 - a^2 \cos \tilde{\theta}^2} (dt + \frac{a \sin^2 \tilde{\theta}}{\Xi} d\tilde{\phi})^2. \]

The anti-self-dual connection \( \omega^i_\perp \) is in this case

\[
\omega^1_\perp = -\frac{1}{\tilde{r} - a \cos \tilde{\theta}} \sqrt{(1 - a^2 \cos \tilde{\theta}^2)(\tilde{r}^2 - a^2)(1 - \tilde{r}^2)} \sin \tilde{\theta} \, d\tilde{\phi},
\]

\[
\omega^2_\perp = (\tilde{r} - a \cos \tilde{\theta}) dt + \frac{1}{\tilde{r} - a \cos \tilde{\theta}} W(\tilde{r}, \tilde{\theta}) d\tilde{\phi},
\]

\[
\omega^3_\perp = \frac{1}{\tilde{r} - a \cos \tilde{\theta}} \left( \sqrt{\frac{\tilde{r}^2 - a)(1 - \tilde{r}^2)}{1 - a^2 \cos^2 \tilde{\theta}} d\tilde{\theta} - \sqrt{\frac{1 - a^2 \cos^2 \tilde{\theta}}{(\tilde{r}^2 - a^2)(1 - \tilde{r}^2)} a \sin \tilde{\theta} d\tilde{r} \right),
\]

(3.49)

where we have defined the function

\[
W(\tilde{r}, \tilde{\theta}) = [(\tilde{r} - a \cos \tilde{\theta})^2 - a + (1 + a^2) \tilde{r} \cos \tilde{\theta} - a \tilde{r}^2 \cos^2 \tilde{\theta}].
\]

(3.50)

The parameter \( a \) is usually called rotational parameter, although we have no the notion of rotational black hole in euclidean signature. The mass parameter \( s \) and the nut charge are zero in this case.

### 3.2 Toric quaternion Kahler spaces

We turn now to more general toric quaternion Kahler orbifolds, following [95]. As we have mentioned, in four dimensions quaternion Kahler spaces are the same than Einstein spaces with self-dual Weyl tensor. The self-duality condition is conformally invariant. This means that if a metric \( g \) is self-dual, then all the family \( [g] \) of metrics obtained by \( g \) by conformal transformations is self-dual. The Einstein condition instead is not invariant under conformal transformations.

Let us focus first in the construction of self-dual families with \( U(1) \times U(1) \) isometry, the Einstein condition will be considered afterwards. For any representative \( g \) of a toric conformal family \( [g] \) there exist a coordinate system for which the metric is expressed in the Gowdy form

\[
g = g_{ab} dx^a dx^b + g_{a\beta} dx^a dx^\beta. \tag{3.51}
\]

The latin and greek indices takes values 1 and 2. Both \( g_{ab} \) and \( g_{a\beta} \) are supposed to be independent of the coordinates \( x^\alpha = (\alpha, \beta) \). The Killing vectors are then \( \partial_\alpha \) and \( \partial_\beta \) and are commuting, so there is a \( U(1) \times U(1) \) action on the manifold. This considerations are local and no assumption about the \( U(1) \) actions is made.\(^1\)

\(^1\)We are loosely speaking about toric conformal families. If a metric \( g \) has two commuting Killing vectors \( \partial_\alpha \) and \( \partial_\beta \), then by a conformal transformation \( g \rightarrow \Omega^2 g \) depending on \( (\alpha, \beta) \) we will obtain a new metric which is not toric anymore. Along this section the \( \Omega \)s are supposed to be independent on \( (\alpha, \beta) \). In this case it is ensured that \( \partial_\alpha \) and \( \partial_\beta \) will be Killing vectors of every metric in \( [g] \).
Clearly, the part $g_{ab}dx^adx^b$ in (3.51) can be interpreted as a two dimensional metric. By a theorem due to Gauss it is known that every two dimensional metric is conformally flat. Therefore the anzatz (3.51) can be written as

$$g = \Omega^2(d\rho^2 + d\eta^2) + g_{\alpha\beta}dx^\alpha dx^\beta,$$

(3.52)

being now $g_{\alpha\beta}$ functions of the coordinates $(\rho, \eta)$ and $\Omega$ a conformal factor with the same coordinate dependence. Because self-duality is conformally invariant we can make a conformal transformation to (3.52) and consider the following metric

$$\widetilde{g} = \frac{(d\rho^2 + d\eta^2)}{\rho^2} + \alpha_{\alpha\beta}dx^\alpha dx^\beta,$$

(3.53)

without losing generality. The factor $\rho^2$ was introduced by convenience. It is natural to express $\alpha_{\alpha\beta}dx^\alpha dx^\beta$ in terms of certain functions $\mathcal{A}_i$ and $\mathcal{B}_i$ $(i=1,2)$ of $(\rho, \eta)$ as

$$\alpha_{\alpha\beta}dx^\alpha dx^\beta = (\mathcal{A}_0d\theta - \mathcal{B}_0d\phi)^2 + (\mathcal{A}_1d\theta - \mathcal{B}_1d\phi)^2.$$  

(3.54)

But this is not the most simplifying form in order to impose the self-duality condition. It is more convenient to write it as

$$\alpha_{\alpha\beta}dx^\alpha dx^\beta = \frac{(A_0d\theta - B_0d\phi)^2 + (A_1d\theta - B_1d\phi)^2}{(A_0B_1 - A_1B_0)^2},$$

(3.55)

in terms of new functions $A_i$ and $B_i$. The relation with the other functions $\mathcal{A}_i$ and $\mathcal{B}_i$ is given by comparison of the last two expressions. Although considering the anzatz (3.55) could seem non practical, the self-duality condition became a linear differential system in terms of $A_i$ and $B_i$.

Therefore it is better to impose the self-duality condition to

$$\widetilde{g} = \frac{(d\rho^2 + d\eta^2)}{\rho^2} + \frac{(A_0d\theta - B_0d\phi)^2 + (A_1d\theta - B_1d\phi)^2}{(A_0B_1 - A_1B_0)^2}.$$  

(3.58)

An intuitive argument to see that an anzatz of the form (3.58) could simplify the self-duality condition goes as follows. It is known that for any group of four vector fields $e_i$, the Ashtekar et al. equations

$$[e_1, e_2] + [e_3, e_4] = 0, \quad [e_1, e_3] + [e_4, e_2] = 0, \quad [e_1, e_4] + [e_2, e_3] = 0,$$

define a self-dual metric $g = \delta_{ab}e^a \otimes e^b$ (here $e_i$ is the dual basis of $e^a$) called hypercomplex metric. The reader can check that if we select the following soldering forms

$$e^1 = d\rho, \quad e^2 = d\eta, \quad e^3 = \frac{A_0d\theta - B_0d\phi}{A_0B_1 - A_1B_0}, \quad e^4 = \frac{A_1d\theta - B_1d\phi}{A_0B_1 - A_1B_0},$$

for the metric (3.58) then the inverse basis take the simple form

$$e_1 = \partial_{\rho}, \quad e_2 = \partial_{\eta}, \quad e_3 = B_1\partial_{\theta} + A_1\partial_{\phi}, \quad e_4 = B_0\partial_{\theta} + A_0\partial_{\phi},$$

(3.56)

(3.57)

and the Ashtekar conditions became simply Cauchy-Riemann equations

$$(A_1)_{\rho} = (A_0)_{\eta}, \quad (A_0)_{\rho} = -(A_1)_{\eta},$$

$$(B_1)_{\rho} = (B_0)_{\eta}, \quad (B_0)_{\rho} = -(B_1)_{\eta},$$

which are linear. If (3.54) is used instead, then the resulting system will take a non linear "look".
If also the commuting Killing vectors are surface orthogonal, then the condition $W = *W$ give the linear system
\begin{align*}
(A_0)_\rho + (A_1)_\eta & = A_0/\rho, \quad (3.59) \\
(A_0)_\eta - (A_1)_\rho & = 0, \quad (3.60)
\end{align*}
and the same equations for $B_i$. This system was found by Joyce in \[102\]. Surface orthogonality implies that the manifold $M$ corresponding to \(3.58\) is of the form $M = N \times T^2$, being $T^2$ the two dimensional torus. There exists other examples (as those in the footnote) which are solution of the self-duality conditions but for which this decomposition do not hold.

The linear system \(3.59\) and \(3.60\) is enough simple. It is easy to check that \(3.60\) implies the existence of a potential function $G$ such that
\begin{align*}
A_0 & = G_\rho; \quad A_1 = G_\eta. \quad (3.61)
\end{align*}
Then \(3.59\) gives that $G_{\rho\rho} + G_{\eta\eta} = G_\rho/\rho$. Inversely we deduce from \(3.59\) the existence of another potential $V$ such that
\begin{align*}
A_0 & = -\rho V_\eta; \quad A_1 = \rho V_\rho, \quad (3.62)
\end{align*}
and \(3.60\) gives the Ward monopole equation \[71\]
\begin{align*}
V_{\eta\eta} + \rho^{-1}(\rho V_\rho)_\rho & = 0. \quad (3.63)
\end{align*}
The relations
\begin{align*}
G_\rho & = -\rho V_\eta; \quad G_\eta = \rho V_\rho, \quad (3.64)
\end{align*}
constitute a Backlund transformation allowing to find a monopole $V$ starting with a known potential $G$ or viceversa. The functions $B_i$ can be also expressed in terms of another potential functions $G'$ and $V'$ satisfying the same equations than $V$ and $G$.

The next task is to extract the Einstein representatives of the self-dual families defined in \(3.58\). This will be automatically quaternion Kahler. In general, to impose the Einstein condition directly to \(3.58\) could give no results. In order to be general, a transformation $\bar{g} \rightarrow \Omega^2 \bar{g}$ should be made to the metrics \(3.58\) and the Einstein condition $R_{ij} = \Lambda g_{ij}$ should be imposed to the transformed metrics. This requirement will fix the factor $\Omega$ and will give further relations between $A_i$ and $B_i$. The result obtained from this condition is that
\begin{align*}
A_1 B_0 - A_0 B_1 & = \rho (A_0^2 + A_1^2) - G A_0, \quad (3.65)
\end{align*}
and that $\Omega^2 = G$. From \(3.65\) it is obtained that $B_0 = \rho A_1 + \xi_0$ and $B_1 = G - \rho A_0 + \xi_1$ with $A_1 \xi_0 = A_0 \xi_1$. The functions $\xi_i$ are determined by the requirement that $B_i$ also satisfy the Joyce system \(3.59\) and \(3.60\), the result is $\xi_0 = -\eta A_0$ and $\xi_1 = -\eta A_1$. Then it is obtained that
\begin{align*}
A_0 & = G_\rho; \quad A_1 = G_\eta \quad (3.66) \\
B_0 & = \eta G_\rho - \rho G_\eta; \quad B_1 = \rho G_\rho + \eta G_\eta - G. \quad (3.67)
\end{align*}
By defining $G = \sqrt{\rho F}$ it follows from the equation $G_{\rho \rho} + G_{\eta \eta} = G_{\rho}/\rho$ that $F$ satisfies

$$F_{\rho \rho} + F_{\eta \eta} = \frac{3F}{4\rho^2}.$$ 

The final expression of the metric is

$$g_q = \frac{F^2 - 4\rho^2(F^2_\rho + F^2_\eta)}{4F^2} \, d\rho^2 + d\eta^2 + \frac{[(F - 2\rho F_\rho)u - 2\rho F_\eta v]^2 + [-2\rho F_\eta u + (F + 2\rho F_\rho) v]^2}{F^2[F^2 - 4\rho^2(F^2_\rho + F^2_\eta)]},$$

where $u = \sqrt{\rho}d\alpha$, $v = (d\beta + \eta d\alpha)/\sqrt{\rho}$ and $F(\rho, \eta)$ is a solution of the equation

$$F_{\rho \rho} + F_{\eta \eta} = \frac{3F}{4\rho^2}$$

on some open subset of the half-space $\rho > 0$.

There exist a theorem that insure that a toric quaternion Kahler manifold will always have surface orthogonal Killing vectors. Therefore the metrics (3.68) are the most general toric quaternion Kahler ones. On the open set defined by $F^2 > 4\rho^2(F^2_\rho + F^2_\eta)$ $g$ has positive scalar curvature, whereas $F^2 < 4\rho^2(F^2_\rho + F^2_\eta)$ $-g$ is self-dual with negative scalar curvature. This are known as the Calderbank-Pedersen metrics.

### 3.3 The manifolds of the family: CP(2) and $S^4$

If we choose a potential $F$ independent on the coordinate $\eta$, then it is obtained from (3.69) that it should be of the form $F(\rho) = \rho^{3/2} - c\rho^{-1/2}$ being $c$ a constant. In this case the metric (3.68) will have the explicit form

$$g_K = \frac{\rho^2 + c}{(\rho^2 - c)^2}(d\rho^2 + d\eta^2 + \frac{d\alpha^2}{4}) + \frac{\rho^2}{(\rho^2 - c)(\rho^2 + c)}(d\beta + \eta d\alpha)^2,$$

and the isometry group will be enlarged by the presence of a new Killing vector $\partial_\eta + \beta \partial_\alpha$. The action of the isometry group on the coordinates is given by

$$\alpha \rightarrow \alpha + a_1, \quad \eta \rightarrow \eta + a_2, \quad \beta \rightarrow \beta + a_3 - a_2 \alpha,$$

being $a_i$ constant parameters. It is worthy to mention that the maximally symmetric quaternion Kahler spaces possess $SO(5)$ or $SO(4, 1)$ isometry group, therefore there are can be at most two commuting isometries in a 4-dimensional quaternion Kahler space. In other words, it is impossible that the third isometry will commute with the others. Indeed the three Killing vectors $T_i$ satisfy the three dimensional Heisenberg algebra

$$[T_1, T_3] = T_2, \quad [T_1, T_2] = [T_3, T_2] = 0.$$
The isometry group (3.71) preserve the triplet (4.101).

If also \( c = 0 \) then the potential function is \( F = \rho^{3/2} \) and the expression for the quaternion Kahler metric will be

\[
g_K = \frac{1}{\rho^2}(d\rho^2 + d\eta^2 + \frac{d\alpha^2}{4}) + \frac{1}{\rho^4}(d\beta + \eta d\alpha)^2. \tag{3.73}
\]

Let us introduce the two form

\[
\mathcal{T} = \frac{d\alpha \wedge d\eta}{2\rho^2} + d\big(\frac{1}{2\rho^2}\big) \wedge (d\beta + \eta d\alpha),
\]

which preserved locally under the action (3.71). The \((1, 1)\) tensor \( J' \) defined through the relation \( g_q(\cdot, J' \cdot) = \mathcal{T} \) is an almost complex structure defined over the quaternion Kahler space \( M \). The two form \( \mathcal{T} \) is evidently closed, thus sympletic and it can be expressed \( \mathcal{T} = dA \) being the one form \( A \) given by

\[
A = -\frac{(d\beta + \eta d\alpha)}{2\rho^2}. \tag{3.74}
\]

By introducing the complex quantities

\[
S = \rho^2 + i(2\beta + \eta\alpha) + C\overline{C}, \quad C = i\eta + \frac{1}{2}\alpha, \tag{3.75}
\]

it follows that the metric (3.73) can be written as

\[
g_K = u \otimes \overline{u} + v \otimes \overline{v} \tag{3.76}
\]

where

\[
u = \frac{1}{\rho} dC, \quad v = \frac{1}{2\rho^2}(dS + C d\overline{C}). \tag{3.77}
\]

This is the classical metric of the universal dilaton hypermultiplet [105] and is known to be Kahler with Kahler potential

\[
K = \log(S + \overline{S} - 2C\overline{C}). \tag{3.78}
\]

This means that space \( M \) is not only sympletic, but Kahler. It is also quaternion-Kahler (thus Einstein), therefore is Kahler-Einstein. The form (3.74) is expressed in the coordinates \((S, C, \overline{S}, \overline{C})\) as

\[
A = 2\bigg(\frac{dS - d\overline{S} + C d\overline{C} - \overline{C} dC}{S + \overline{S} - 2C\overline{C}}\bigg). \tag{3.79}
\]

By going to the coordinate system defined by

\[
z_1 = \frac{1 - S}{1 + S}, \quad z_2 = \frac{2C}{1 + S}
\]

26
it is recognized that (3.77) is the Bargmann metric

\[
g_\tau = \frac{dz_1 d\bar{z}_1 + dz_2 d\bar{z}_2}{1 - |z_1|^2 - |z_2|^2} - \frac{(z_1 d\bar{z}_1 + z_2 d\bar{z}_2)(\bar{z}_1 dz_1 + \bar{z}_2 dz_2)}{(1 - |z_1|^2 - |z_2|^2)^2},
\]

defined over the unit open ball in \(C^2\) given by \(|z_1|^2 + |z_2|^2 < 1\), with Kahler potential \(K = \log(1 - |z_1|^2 - |z_2|^2)\). This space is topologically equivalent to the homogeneous symmetric space \(SU(2,1)/SU(2) \times SU(1)\). By going to spherical coordinates

\[
z_1 = r \cos \frac{u}{2} \exp(i \frac{v + w}{2}), \quad z_2 = r \sin \frac{u}{2} \exp(-i \frac{v - w}{2}),
\]

with \(0 < r < 1, 0 < u < \pi, 0 < v < 2\pi\) and \(0 < w < 4\pi\), the Bargmann metric take the Bianchi IX form

\[
g_\tau = \frac{dr^2}{(1 - r^2)^2} + \frac{r^2 \sigma_1^2}{(1 - r^2)^2} + \frac{r^2 (\sigma_2^2 + \sigma_3^2)}{1 - r^2}
\]

with manifest \(SU(2)\) symmetry.

Let us note that the metrics (3.73) can be extended with no difficulty to an Einstein-Sasaki space in five dimensions by use of (2.9), the local form of such metrics is

\[
g_{cs} = [d\tau - \frac{(d\beta + \eta d\alpha)}{2 \rho^2}]^2 + \frac{1}{\rho^2} (d\rho^2 + \eta^2 + \frac{d\alpha^2}{4}) + \frac{1}{\rho^4} (d\beta + \eta d\alpha)^2,
\]

and is seen that the isometry group (3.71) is an isometry of (3.82). We have three commuting Killing vectors, namely \(\partial_\alpha, \partial_\beta\) and \(\partial_\tau\), and so there is a \(T^3\) action.

For the Bargmann metric \(F^2 < 4\rho^2 F_\rho^2\) and this means that \(\kappa < 0\). Thus the construction of tri-Sasaki metrics presented in previous sections can not be applied to this example. But by making the replacement \(z_i \rightarrow iz_i\) the Kahler potential of the Bargmann metric will be converted into \(K = \log(1 + |z_1|^2 + |z_2|^2)\). This is the potential for the Fubbini-Study metric over \(CP(2)\), which is dual to the Bargmann one. This metric is also Kahler-Einstein and quaternion Kahler. Its metric tensor and the corresponding potential form \(A\) can obtained from the formulas corresponding to the Bargmann metric by making the replacement \(z_i \rightarrow iz_i\). But different from the Bargmann metric, this metric possess positive scalar curvature and the construction presented in previous section can be applied. The anti self-dual part of the spin connection of the Fubbini-Study metric is given by

\[
\omega_1^\tau = -\frac{1}{2} \left( \frac{\bar{z}_2 d\bar{z}_1 + z_2 d\bar{z}_1}{(1 + |z_1|^2) \sqrt{1 + |z_1|^2 + |z_2|^2}} \right), \quad \omega_2^\tau = \frac{i}{2} \left( \frac{\bar{z}_2 d\bar{z}_1 - z_2 d\bar{z}_1}{(1 + |z_1|^2) \sqrt{1 + |z_1|^2 + |z_2|^2}} \right),
\]

\[
\omega_3^\tau = \frac{i}{2} \left( \frac{\bar{z}_1 d\bar{z}_1 - z_1 d\bar{z}_1 + z_2 d\bar{z}_2 - \bar{z}_2 dz_2}{(1 + |z_1|^2)} \right).
\]

From (2.20) it is obtained the tri-Sasaki metric

\[
g_\tau = (\sigma_i - \omega_\tau^i)^2 + \frac{dz_1 d\bar{z}_1 + dz_2 d\bar{z}_2}{1 + |z_1|^2 + |z_2|^2} - \frac{(z_1 d\bar{z}_1 + z_2 d\bar{z}_2)(\bar{z}_1 dz_1 + \bar{z}_2 dz_2)}{(1 + |z_1|^2 + |z_2|^2)^2},
\]
which is fibered over the Fubbini-Study metric. Here $\sigma_i$ the one Maurer-Cartan forms in (2.21) and $\omega^i_-$ is given in (3.83).

The same procedure can be applied to the sphere $S^4$, which, together with CP(2) constitute the unique 4-dimensional quaternion Kahler spaces that are manifolds. The corresponding Kahler-Einstein and tri-Sasaki metrics are respectively

$$g_6 = \frac{1}{2}d\Omega_4^2 + (d\theta - \sin \varphi A^2 + \cos \varphi A^1)^2$$

$$+(\sin \theta d\varphi - \cos \theta \sin \varphi A^1 - \cos \theta \cos \varphi A^2 + \sin \theta A^3)^2,$$

$$g_7 = (A_i - \sigma^i)^2 + \frac{1}{2}d\Omega_4^2,$$

being $A_i$ the unit charge instantons on $S^4$ and $d\Omega_4^2$ the usual metric for the sphere.

### 3.4 More general quaternion Kahler orbifolds

The space of metrics defined in (3.68) is very rich. They encode many well known examples in the literature as well as new ones. We briefly describe some of them, but a much more complete description can be found in the original references [93]-[94].

The Backlund transformation defined in (3.64) is a correspondence between solutions $F$ of (3.69) and solutions of the Ward monopole equation (3.63). The Ward monopole equation describe hyperKahler metrics with two commuting Killing vectors, which in cylindrical coordinates take the form [71]

$$g = \frac{(dt + \rho V_\rho d\varphi)^2}{V_\eta} + V_\eta (d\rho^2 + d\eta^2 + \rho^2 d\varphi^2). \quad (3.85)$$

Several of these metrics were consider recently in [96]-[97]. The commuting Killing vectors are $\partial_t$ and $\partial_\varphi$. It is not difficult to see that these metrics are hyperKahler. By defining the one form $A = \rho V_\rho d\varphi$ and $U = V_\eta$ the metrics (3.85) take the Gibbons-Hawking form [113]

$$g = V^{-1}(dt + A)^2 + Vdx_i dx_j \delta^{ij}, \quad (3.86)$$

and it follows that $A$ and $V$ satisfy the linear system of equations

$$\nabla V = \nabla \times A. \quad (3.87)$$

Any element of the family (3.87) is hyper-Kähler with respect to the hyper-Kähler triplet

$$\mathcal{J}_1 = (dt + A) \wedge dx - V dy \wedge dz$$

$$\mathcal{J}_2 = (dt + A) \wedge dy - V dz \wedge dx$$

$$\mathcal{J}_3 = (dt + A) \wedge dz - V dx \wedge dy \quad (3.88)$$
which is actually $t$-independent. Therefore the Killing vector $\partial_t$ is tri-holomorphic. Instead $\partial_\varphi$ is not, that is, it do not preserve \[3.88\]. It follows that the Backlund transformation is a correspondence between toric quaternion Kahler spaces and toric hyperKahler spaces with at least one tri-holomorphic isometry.

The elemental solution of the equation \[3.87\] is given by the single Wu-Yang monopole potential $A$ and the scalar field $V$ of the form

$$V = c + \frac{a}{r}, \quad A = \frac{a(ydx - xdy)}{r(r + z)} \quad z > 0, \quad \tilde{A'} = \frac{a(ydx - xdy)}{r(r - z)} \quad z \leq 0, \quad (3.89)$$

being $r$ the radius $r = \sqrt{x^2 + y^2 + z^2}$. The vector potential $A$ is not globally defined in $\mathbb{R}^3$ due to the presence of Dirac string singularities in the upper $z$ axis for $A$ and in the lower $z$ axis for $\tilde{A'}$. In the overlapping region both potentials differ one to each other by a gauge transformation $\tilde{A'} = A - 2a \arctan(y/x)$. Any array of Dirac monopoles will describe an hyperKahler metric, but only if such monopoles are aligned along an axis, then we will have axial symmetry as in the Ward case \[3.85\]. The elementary Ward solutions are of the form

$$U_i = a_i \log(\eta - \eta_i + \sqrt{(\eta - \eta_i)^2 + \rho^2})$$

and represent a monopole located in the position $(0, \eta_i)$. Any superposition of such elementary functions will give rise to a toric hyperKahler metric. The Backlund transformation of the solutions $U_i$ is given by

$$F_i = \sqrt{a_i^2 \rho^2 + (a_i \eta - \eta_i)^2} \rho. \quad (3.90)$$

Any superposition of these solutions, namely

$$F = \sum_{k=1}^{m} \sqrt{a_k^2 \rho^2 + (a_k \eta - b_k)^2} \rho,$$

will give rise to a toric quaternion Kahler metric. There are also elementary solution $F = \rho^{3/2}$ and $F = \rho^{-1/2}$, which are $\eta$-independent.

For $m = 2$ the solutions are called 2-pole functions and are given by

$$F_1 = \frac{1 + \sqrt{\rho^2 + \eta^2}}{\sqrt{\rho}}, \quad F_2 = \frac{\sqrt{(\rho)^2 + (\eta + 1)^2} - \sqrt{(\rho)^2 + (\eta - 1)^2}}{\sqrt{\rho}}.$$

The first one gives rise to the spherical metric, while the second one gives rise to the hyperbolic metric. This is seen by defining the coordinates $(r_1, r_2)$ which are related to the hyperbolic ones $(\rho, \eta)$ by the relation

$$(r_1 + ir_2)^2 = \frac{\eta - 1 + i\rho}{\eta + 1 + i\rho}.$$
By writing the corresponding metric in terms of \((\rho, \eta)\) and making the change to \((r_1, r_2)\) gives
\[
g = (1 - r_1^2 - r_2^2)^{-2}(dr_1^2 + dr_2^2 + r_1^2 d\theta_1^2 + r_2^2 d\theta_2^2),
\]
which is the hyperbolic metric on the unit ball on \(R^4\). This is a conformally flat metric.

Now, let us discuss the case of two monopoles on the \(z\) axis. Without losing generality, it can be considered that the monopoles are located in the positions \((0, 0, \pm c)\). The potentials for this configuration are
\[
V = \frac{1}{r_+} + \frac{1}{r_-}, \quad A = A_+ + A_- = \left(\frac{z_+}{r_+} + \frac{z_-}{r_-}\right) d\arctan(y/x), \quad r_{\pm} = \sqrt{x^2 + y^2 + (z \pm m)^2}.
\]
This case corresponds to the Eguchi-Hanson instanton, whose metric, in Cartesian coordinates, reads
\[
g = \left(\frac{1}{r_+} + \frac{1}{r_-}\right)^{-1} \left( dt + \left(\frac{z_+}{r_+} + \frac{z_-}{r_-}\right) d\arctan(y/x)\right)^2 + \left(\frac{1}{r_+} + \frac{1}{r_-}\right) (dx^2 + dy^2 + dz^2).
\]
In order to recognize the Eguchi-Hanson metric in its standard form it is convenient to introduce a new parameter \(a^2 = 8m\), and the elliptic coordinates defined by
\[
x = \frac{r^2}{8}\sqrt{1 - (a/r)^4 \sin \varphi \cos \theta}, \quad y = \frac{r^2}{8}\sqrt{1 - (a/r)^4 \sin \varphi \sin \theta}, \quad z = \frac{r^2}{8}\cos \varphi.
\]
In this coordinate system it can be checked that
\[
r_{\pm} = \frac{r^2}{8} \left(1 \pm (a/r)^2 \cos \varphi\right), \quad z_{\pm} = \frac{r^2}{8} \left(\cos \varphi \pm (a/r)^2\right), \quad V = \frac{16}{r^2} \left(1 - (a/r)^4 \cos^2 \varphi\right)^{-1},
\]
\[
A = 2 \left(1 - (a/r)^4 \cos^2 \varphi\right)^{-1} \left(1 - (a/r)^4\right) \cos \varphi d\theta,
\]
and, with the help of these expressions, it is found
\[
g = \frac{r^2}{4} \left(1 - (a/r)^4\right) \left(d\theta + \cos \varphi d\tau\right)^2 + \left(1 - (a/r)^4\right)^{-1} dr^2 + \frac{r^2}{4} \left(d\varphi^2 + \sin^2 \varphi d\tau\right)
\]
being \(\tau = 2t\). This is actually a more familiar expression for the Eguchi-Hanson instanton, indeed [114]. Let us also note that the Eguchi-Hanson metric corresponds to two monopoles in the \(z\) axis, but if we choose \(m^2 = -1\) this will correspond to a to the potential for an axially symmetric circle of charge. The corresponding metric is called Eguchi-Hanson metric of the type I, and is always incomplete.

Let us go back to the Backglund transformed geometry corresponding to the Eguchi-Hanson metric. The general ”3-pole” solutions can be written as
\[
F = \frac{a}{\sqrt{\rho} + \frac{b + c/m}{2} \sqrt{\rho^2 + (\eta + m)^2}} + \frac{b - c/m}{\sqrt{\rho^2 + (\eta - m)^2}}.
\]
By definition \(-m^2 = \pm 1\), which means that \(m\) can be imaginary or real. The corresponding solutions are denominated type I and type II respectively, by analogy with the hyperKahler case. It is interesting to note that for \(c = 0\) and \(b = -1\) and defining the coordinates \((t, \theta)\) by \(\eta = (\cosh^2 t - 1) \cos \theta\) and \(\rho = 2 \coth t \sinh^{-1} t \sin \theta\) the metric take the form

\[
g_q = 4dt^2 + \sinh^2 t (d\theta^2 + \sin^2 \theta d\phi^2) + \frac{\sinh^2 2t}{2} (d\psi + \cos \theta d\phi)^2.
\]

By making the further transformation \(2t = \log(1 + r) - \log(1 - r)\) this metric take the form (3.81) and therefore it is the Bargmann metric. The Bargmann metric can also be obtained with the function \(F = \rho^{3/2}\) and this means that different solutions of the equation (3.69) can give rise to the same metric. In fact, the Bargmann metric can be recovered for \(c = 0\) and \(b = 1\) and also for \(c = 1\) and \(b = 0\). There exist certain freedom in the choice of \(F\) that leaves the metric invariant. This freedom allows in particular to set \(a = 1\). If \(c = 0\) and \(b\) is arbitrary then the metric reduces to the Pedersen metric [99] (see also [95])

\[
g_q = \left(\frac{w^2 + q^2}{w - sqr^2}\right)^2 \left(\frac{wr^2 + s}{1 + qr^2} dr^2 + \frac{r^2}{4} \left(\frac{1 + qr^4}{wr^2 + s} \sigma_1^2 + (wr^2 + s)(\sigma_2^2 + \sigma_3^2)\right)\right),
\]  

being \(w, q\) and \(s\) three parameters. We should be aware that these metrics possesses only one parameter up to an homothety, the other two can be selected to one by a suitable rescaling. This is in accordance with that, by construction, the only parameter is \(b\). The advantage of this notation is that several limits are better understood. The scalar curvature of this metrics is \(-48wq/(w^2 + q^2)\) and we see that in the limit \(w = 0\) or \(q = 0\) the metric will be hyperKahler. In the first case the metric reduces to the Taub-Nut one [115], in the second it corresponds to the I and II Eguchi-Hanson metrics.

It is natural to introduce the cylindrical coordinate system

\[
\rho = \sqrt{R^2 + 1} \cos \theta, \quad \eta = R \sin \theta,
\]

where \(\theta\) takes values in the interval \((-\pi/2, \pi/2)\). In these coordinates

\[
\sqrt{\rho} F = 1 + bR + c \sin \theta, \quad \rho^{-1}\left[\frac{1}{4} F^2 - \rho^2 (F_\rho^2 + F_\eta^2)\right] = \frac{b(R \mp b) + c(\sin \theta + c)}{R^2 \pm \sin^2 \theta}.
\]

The zeroes of \(F\) are the conformal infinite of the metric, while the zeroes of \(\frac{1}{4} F^2 - \rho^2 (F_\rho^2 + F_\eta^2)\) are singularities separating the domains of positive and negative scalar curvature. For the type II metrics the coordinate \(R\) can take values between 1 and \(\infty\). For \(b = 1\) and \(c = 0\) it is obtained the Fubbini-Study metric on CP(2), while for \(b = -1\) and \(c = 0\) or \(b = 0\) and \(c = \pm 1\) it is obtained the Bargmann metric. By introducing the vector \((b, c)\) we have that along the lines joining these four points the metrics will be bi-axial Bianchi. Along the lines joining \((1, 0)\) with the other points there will live Bianchi IX metrics whereas on the lines between \((-1, 0)\), \((0, 1)\) and \((0, -1)\) the metric is Bianchi
VIII. For the type I metrics the value of $R$ is non restricted. The zeroes of $F$ defining the conformal infinite are $R_\infty = -(1 + c \sin \theta)/b$. The zeroes of $\frac{1}{4} F^2 - \rho^2 (F^2_\rho + F^2_\eta)$ are $R_\pm = (b^2 + c^2 + c \sin \theta)/b$. The case $b = 0$ and correspond to Bianchi VIII metrics. If $c = 0$ we obtain the Pedersen metrics. The conformal infinite is $R_\infty = 1/b$ and $R_\pm = b$.

There have been found certain quaternion Kahler deformations of the Taub-Nut gravitational instantons and other examples in [100], and the relation between these metrics and the $m$-pole solutions has been worked out in that reference. Also we would like to remark that the orbifolds (3.41) can be represented in the form (3.68) but the coordinate change is rather complicated and we will not describe it here, see [74]-[73]. Higher multi-instanton solutions, or $m$-pole solutions are a linear combinations of the form

$$F = \sum_k a_k^2 \rho^2 + (a_k \eta - b_k)^2 \sqrt{\rho}$$

for some real parameters $(a_k, b_k)$ for $1 < k < m$. But there is an $SL(2, R)$ action that leaves the metric invariant up to an overall factor and therefore, as a vector space, $(a_k, b_k)$ is $2m - \dim SL(2, R) - 1 = 2(m-2)$-dimensional. The $m$-pole solutions arise as quaternion-Kahler quotients of $H^{m-1}$ by an $(m-2)$ dimensional subtorus of a maximal torus $T^m$ in $Sp(m)$, all these metrics are therefore defined on a compact orbifolds [77]. Applications of them to the universal hypermultiplet have been found, for instance in [103]-[105]. Other applications has been considered in [88]-[90].

4. Explicit tri-Sassaki and weak $G_2$ metrics and supergravity solutions

4.1 Tri-Sassaki and weak $G_2$ over AdS-Kerr and AdS-Taub-Nut

We are now in position to construct compact tri-Sasaki and weak $G_2$ holonomy metrics. The main ingredient in this construction is the proposition 1, applied to limiting cases of the euclidean Plebanski-Demianski solution (3.48) or to the toric metrics (3.68). But before to start is convenient to mention that there exist in the literature Einstein-Sasaki spaces fibered over the so called "orthotoric" Kahler-Einstein spaces [40]-[41]. As was show in [41] this spaces can be obtained by taking certain scaling limit of the euclidean Plebanski-Demianski metrics (3.48). In particular, there were found several toric Einstein-Sasaki metrics defined over $S^2 \times S^3$. Nevertheless, those spaces are 5-dimensional and are fibrations over 4-dimensional Kahler-Einstein spaces. Instead, we are presenting a 7-dimensional family which is fibered over 4-dimensional quaternion Kahler spaces. Thus, in principle, our examples bears no relation to those found in [40]-[41].

After this comment, we turn our attention now to the construction of tri-Sasaki (and weak $G_2$) metrics implicit in proposition 1.
The AdS-Taub-Nut case

It is direct, by using proposition 1 and the lifting formula (2.37), to work out tri-Sassaki and weak $G_2$ holonomy metrics fibered over the AdS-Taub-Nut metrics (3.45), the result is

\[ g_7 = \left( \sqrt{(r + N)V(r)} \sin \tilde{\theta}d\tilde{\phi} + \sigma_1 \right)^2 + \left( (r - N)d\tilde{t} + g(r) \cos \tilde{\theta}d\tilde{\phi} - \sigma_2 \right)^2 \]

\[ + \left( \sqrt{(r + N)V(r)}d\tilde{\theta} - \sigma_3 \right)^2 + b \left( V(r)(d\tilde{t} - 2N \cos \tilde{\theta}d\tilde{\phi})^2 + \frac{d\tilde{t}^2}{V(r)} + (r^2 - N^2)(d\tilde{\theta}^2 + \sin^2 \tilde{\theta}d\tilde{\phi}^2) \right). \]

Although the base quaternion Kahler space possess $SU(2) \times U(1)$ isometry, this group does not preserve the fibers, so the isometry group is $SU(2) \times U(1)^2$, being the $SU(2)'$ group related to the Maurer-Cartan forms of the fiber metric and $U(1)^2$ generated by $\partial_{\tilde{t}}$ and $\partial_{\tilde{\phi}}$. Let us notice that we have a third commuting Killing vector, which is the Reeb vector $\partial_r$, which is present in the expression for the Maurer-Cartan forms $\sigma_i$. Therefore we have a $T^3$ subgroup of isometries. By taking into account the explicit form of the $\sigma_i$'s given in (2.21) we obtain the following metric components

\[ g_{\tilde{t}\tilde{t}} = (r - N)^2 + bV(r), \quad g_{\tilde{t}\phi} = 4bN^2V(r) \cos^2 \tilde{\theta} + (r^2 - N^2) \sin^2 \tilde{\theta} \]

\[ g_{\tilde{t}\theta} = b(r^2 - N^2) + (r + N)V(r), \quad g_{\tilde{t}\tau} = \frac{b}{V(r)}, \quad g_{\tau\tau} = g_{\varphi\varphi} = g_{\theta\theta} = 1 \]

\[ g_{\tilde{t}\phi} = -2NbV(r) \cos \tilde{\theta} + (r - N)g(r) \cos \tilde{\theta}, \quad g_{\tilde{t}\tau} = -(r - N) \cos \varphi \sin \theta \]

\[ g_{\varphi\varphi} = \sqrt{(r + N)V(r)} \sin \tilde{\theta} \sin \theta \sin \varphi + g(r) \cos \tilde{\theta} \sin \theta \cos \varphi \]

(4.97)

\[ g_{\phi\phi} = \sqrt{(r + N)V(r)} \sin \tilde{\theta} \cos \varphi + g(r) \cos \tilde{\theta} \sin \varphi \]

\[ g_{\tilde{t}\theta} = -\sqrt{(r + N)V(r)} \cos \theta, \quad g_{\theta\varphi} = -\sqrt{(r + N)V(r)} \]

\[ g_{\tilde{t}\varphi} = -(r - N) \sin \varphi \sin \theta, \quad g_{\tau\varphi} = \cos \theta, \]

the remaining components are all zero. The parameter $b$ take the values 1 or 5, $b = 1$ corresponds to an Einstein-Sassaki metric, while $b = 5$ corresponds to a weak $G_2$ holonomy metric.

The AdS-Kerr-Newmann case

For the rotating case, that is, for the AdS-Kerr-Newman metrics (3.48) we obtain the metrics

\[ g_q = \left( \frac{\sqrt{f(\tilde{\theta})c(\tilde{r})d(\tilde{r})}}{e(\tilde{r}, \tilde{\theta})} \sin \tilde{\theta} \right)^2 + \left( e(\tilde{r}, \tilde{\theta})d\tilde{t} + \frac{W(\tilde{r}, \tilde{\theta})}{\Xi e(\tilde{r}, \tilde{\theta})} d\tilde{\phi} - \sigma_2 \right)^2 \]

(4.98)
The local isometry is $SU(2) \times U(1)^2$ and as before, the vectors $\partial_{\tilde{r}}$, $\partial_{\tilde{\theta}}$, and $\partial_{\tau}$ generate a $T^3$ isometry subgroup. From expression (4.98) we read the following components

$$g_{\tilde{r}\tilde{r}} = \frac{b \, c(\tilde{r})d(\tilde{r})}{\tilde{r}^2 - a^2 \cos^2 \tilde{\theta}} + a^2 \frac{b \, f(\tilde{\theta}) \sin^2 \tilde{\theta}}{\tilde{r}^2 - a^2 \cos^2 \tilde{\theta}} + e^2(\tilde{r}, \tilde{\theta})$$

$$g_{\tilde{\phi}\tilde{\phi}} = \frac{b \, c(\tilde{r})d(\tilde{r})}{\tilde{r}^2 - a^2 \cos^2 \tilde{\theta} \Xi^2} + b \, f(\tilde{\theta}) \sin^2 \tilde{\theta} \frac{c^2(\tilde{r})}{\Xi^2} + W^2(\tilde{r}, \tilde{\theta}) \frac{f(\tilde{\theta})c(\tilde{r})d(\tilde{r}) \sin^2 \tilde{\theta}}{\Xi^2 e^2(\tilde{r}, \tilde{\theta})}$$

$$g_{\tilde{\theta}\tilde{\theta}} = \frac{\tilde{r}^2 - a^2 \cos^2 \tilde{\theta} b + 1}{f(\tilde{\theta})} \frac{c(\tilde{r})d(\tilde{r})}{f(\tilde{\theta})}, \quad g_{\tilde{r}\tilde{\phi}} = \frac{-a \sin \tilde{\theta}}{e^2(\tilde{r}, \tilde{\theta})}, \quad g_{\tilde{r}\tilde{\theta}} = \frac{-\sqrt{f(\tilde{\theta})c(\tilde{r})d(\tilde{r}) \sin \tilde{\theta}}}{e(\tilde{r}, \tilde{\theta})}$$

$$g_{\tilde{\phi}\tilde{\theta}} = \frac{W(\tilde{r}, \tilde{\theta})}{\Xi e(\tilde{r}, \tilde{\theta})} \sin \varphi + \frac{\sqrt{f(\tilde{\theta})c(\tilde{r})d(\tilde{r}) \sin \tilde{\theta}}}{e(\tilde{r}, \tilde{\theta})} \cos \varphi$$

$$g_{\tilde{r}\tilde{r}} = -\frac{\sqrt{f(\tilde{\theta})c(\tilde{r})d(\tilde{r}) \sin \tilde{\theta}}}{f(\tilde{\theta}) e(\tilde{r}, \tilde{\theta})}, \quad g_{\tilde{r}\tilde{\phi}} = -\frac{c(\tilde{r})d(\tilde{r})}{f(\tilde{\theta}) e(\tilde{r}, \tilde{\theta})} \frac{1}{e(\tilde{r}, \tilde{\theta})}$$

and the other components are zero. In the limit $a = 0$ the base metric reduce to $S^4$, the resulting tri-Sasaki metrics is

$$g_{\tilde{r}} = (\sin \tilde{\rho} d\tilde{r} + \cos \tilde{\rho} d\tilde{\phi} + \sin \varphi d\theta - \cos \varphi \sin \theta d\tau)^2 + (\cos \tilde{\rho} d\tilde{\theta} - d\varphi - \cos \theta d\tau)^2$$

$$+ (\cos \tilde{\rho} \sin \tilde{\theta} d\tilde{\phi} - \cos \varphi d\theta - \sin \varphi \sin \theta d\tau)^2 + b \cos^2 \tilde{\rho} d\tilde{\theta}^2 + b d\tilde{\rho}^2 + b \sin^2 \tilde{\rho} (d\tilde{\theta}^2 + \sin^2 \tilde{\theta} d\tilde{\phi}^2).$$

By another side, the tri-Sasaki and weak $G_2$ metrics fibered over CP(2) are those corresponding to the spaces $N(1,1)_I$ and $N(1,1)_II$ and were given in (2.40), so we will not discuss them again.
4.2 An infinite family of weak G2 and tri-Sasaki orbifolds

Let us now turn our attention to the construction of the tri-Sasaki and the Kahler-Einstein metrics fibered over the toric quaternion Kahler metrics \((3.69)\). The anti-self-dual part of the spin connection \(\omega^i\) possess a remarkable simple form in terms of the potential function \(F\):\[\omega^{i} = \frac{1}{F}[\frac{\rho F_{\eta} \, d\rho}{\rho} + \left(\frac{1}{2} F + \rho F_{\rho}\right) \frac{d\eta}{\rho}], \quad \omega^{2} = \frac{u}{F}, \quad \omega^{3} = \frac{v}{F}.\] (4.101)

The Kahler-Einstein metric defined over the twistor space \(Z\) of \((3.68)\) is obtained directly from \((2.25)\) and is given by
\[
g_{6} = \frac{F^{2} - 4\rho^{2}(F_{\rho}^{2} + F_{\eta}^{2}) \, d\rho^{2} + d\eta^{2}}{\rho^{2}} + \frac{[(F - 2\alpha F_{\rho})u - 2\rho F_{\eta}v]^{2} + [-2\rho F_{\eta}u + (F + 2\rho F_{\rho})v]^{2}}{F^{2}[F^{2} - 4\rho^{2}(F_{\rho}^{2} + F_{\eta}^{2})]}\]
\[+ (d\theta - \sin \varphi \omega^{2} - \cos \varphi \omega^{1})^{2} + (\sin \theta d\varphi - \cos \theta \sin \varphi \omega^{1} - \cos \theta \cos \varphi \omega^{2} + \sin \theta \omega^{3})^{2} \]
(4.102)

The Kahler form for \((4.102)\) is \(\mathcal{J} = dH\) where
\[H = \frac{\sin \theta \sin \varphi}{2\rho F} \left( -2\rho F_{\eta}d\rho + (F + 2\rho F_{\rho})d\eta \right) + \frac{\sin \theta \cos \varphi u}{F} + \frac{\cos \theta v}{F} - \cos \theta d\varphi, \quad (4.103)\]
and with the help of this expressions we obtain the tri-Sasaki metrics
\[g_{7} = (d\tau + H)^{2} + g_{6},\]
being \(H\) defined in \((4.103)\). Both expressions for the tri-Sasaki and the Kahler-Einstein metrics are completely determined in terms of a single eigenfunction \(F\) of the hyperbolic laplacian. Indeed the components of \(g_{7}\) are given explicitly by
\[
(g_{7})_{\rho\rho} = (g_{q})_{\rho\rho} + \frac{F_{\eta}}{F^{2}}(F + 2\rho F_{\rho}), \quad (g_{7})_{\rho\eta} = (g_{q})_{\rho\eta} + \frac{1}{\rho^{2} F^{2}}((F + 2\rho F_{\rho})^{2}, \quad (g_{7})_{\eta\eta} = (g_{q})_{\eta\eta} + \frac{1}{\rho^{2} F^{2}}((F + 2\rho F_{\rho})^{2},
\]
\[
(g_{7})_{\alpha\alpha} = (g_{q})_{\alpha\alpha} + \frac{(1 + \rho^{2})}{\rho F^{2}}, \quad (g_{7})_{\alpha\beta} = (g_{q})_{\alpha\beta} + \frac{2\eta}{\rho F^{2}}, \quad (g_{7})_{\beta\beta} = (g_{q})_{\beta\beta} + \frac{1}{\rho F^{2}}.
\]
\[
(g_{7})_{\rho\theta} = \frac{2F_{\eta}}{F} \cos \theta, \quad (g_{7})_{\rho\tau} = \frac{2F_{\eta}}{F} \sin \theta \sin \varphi, \quad (g_{7})_{\eta\theta} = -\frac{1}{\rho F}(F + 2\rho F_{\rho}) \cos \theta, \quad (g_{7})_{\eta\tau} = -\frac{1}{\rho F}(F + 2\rho F_{\rho}) \sin \theta \sin \varphi, \quad (4.104)
\]
\[
(g_{7})_{\alpha\theta} = \frac{2\sqrt{\rho}}{F} \sin \varphi, \quad (g_{7})_{\alpha\varphi} = -\frac{2\eta}{\sqrt{\rho} F}, \quad (g_{7})_{\alpha\tau} = -\frac{2\sqrt{\rho}}{F} \sin \theta \cos \varphi + \frac{2\eta}{\sqrt{\rho} F} \cos \theta, \quad (g_{7})_{\beta\tau} = \frac{2\sqrt{\rho}}{F} \sin \theta \cos \varphi - \frac{2\eta}{\sqrt{\rho} F} \cos \theta,
\]
35
\[ (g_7)_{\beta\varphi} = -\frac{2}{\sqrt{pF}}, \quad (g_7)_{\beta\tau} = -\frac{2}{\sqrt{pF}} \cos \theta \]
\[ (g_7)_{\theta\theta} = (g_7)_{\tau\tau} = (g_7)_{\varphi\varphi} = 1, \quad (g_7)_{\tau\varphi} = \cos \theta \]
and the remaining components are zero.

The tri-Sasaki metric possesses an \( SU(2) \) isometry group associated with the \( \sigma^i \) and a \( T^2 \) isometry of the quaternion Kahler base. Therefore the isometry group is at least \( SO(3) \times T^2 \). The Killing vectors are
\[ K_1 = \partial_\alpha, \quad K_2 = \partial_\beta \]
\[ K_3 = \partial_\tau, \quad K_4 = \cos \tau \partial_\varphi - \coth \sin \varphi \sin \tau \partial_\theta \]
\[ K_5 = -\sin \tau \partial_\varphi - \coth \sin \varphi \cos \tau \partial_\theta \]
with commutation rule
\[ [K_1, K_i] = [K_2, K_i] = 0, \quad i = 1, \ldots, 5 \quad [K_i, K_j] = \epsilon_{ijk}K_k, \quad i, j, k = 3, 4, 5. \]
Both the tri-Sasaki metric and the Kahler-Einstein one possesses three commuting Killing vectors. For the Kahler Einstein metric the vectors are \( \partial_\theta, \partial_\alpha \) and \( \partial_\beta \), for the tri-Sasaki metric they are \( \partial_\tau, \partial_\alpha \) and \( \partial_\beta \).

By making the replacement \( g_q \rightarrow 5g_q \) in the formulas above we obtain a family of weak \( G_2 \) holonomy metric. Locally the isometry group will be the same than for them than for the tri-Sasaki ones that we have presented.

4.3 Supergravity solutions fibered over Einstein spaces

Let us describe how to construct supergravity backgrounds fibered over conical Ricci-flat metrics and their role in the AdS/CFT correspondence. Consider an stack of \( N \) parallel Dp branes. The general form of such background is
\[ g_{10} = H_{p-1/2}(r)g_{1,p} + H_p^{1/2}(r)(dr^2 + r^2 g_{8-p}), \]
\[ e^{2\phi-2\phi_\infty} = H_p^{-p-3}, \quad A_{p+1} = -\frac{1}{2}(H_p^{-1} - 1)dx^0 \wedge \ldots \wedge dx^p, \quad (4.106) \]
where
\[ H_p(r) = 1 + 2^{p-5}p^{5-p} \frac{g_sN_c}{2} \Gamma\left(\frac{7-p}{2}\right) \frac{\alpha^{7-p}}{r^{7-p}}. \]
The metric \( g_{8-p} \) is Einstein and is assumed to be independent on \( r \) and also independent on the Minkowski coordinates \( (t, x, y, z) \). If the Dp branes are flat, the light open spectrum is \( U(N_c) \) super Yang Mills in \( p + 1 \) dimensions. We have that \( g_{YM} = 2\pi^{p-2}g_s\alpha^{7-p} \), being \( g_s = e^{2\phi_\infty} \). The field theory limit is obtained by taking \( \alpha \rightarrow 0 \) such that \( g_{YM} \) is fixed.
For $p < 3$ the ten dimensional Newton constant goes to zero and the theory is decoupled from the bulk. Instead for $p > 3$ the constant $g_s$ goes to infinite and a dual description is convenient in order to analyze the decoupling problem. In order to have finite energy configurations in the field theory limit one should consider the near horizon limit in the IIB background. Such limit is obtained by taking $r \to 0$ and $\alpha' \to 0$ such that the quantity with energy units $U = r/\alpha'$ is fixed. For any $p$ the resulting metric will be

$$g_{\text{IIB}} = \alpha' \left[ (\frac{d_p g_{YM} N}{U^{7-p}})^{-1/2} g_{\text{AdS}} + (\frac{d_p g_{YM}^2 N}{U^{7-p}})^{1/2} (dU^2 + U^2 d\Omega_{8-p}) \right]$$

$$e^\phi = (2\pi)^{-p} g_{YM}^2 (\frac{d_p g_{YM} N}{U^{7-p}})^{\frac{2-p}{2}}, \quad d_p = 2^{7-2p} \pi^{\frac{2-p}{2}} \Gamma(\frac{7-p}{2}).$$

The Yang-Mills coupling constant $g_{YM}$ is not dimensionless for any $p$, but the effective constant $g_{\text{eff}}^2 \sim g_{YM}^2 N U^{p-3}$ is. The low energy description of super Yang-Mills can be trusted for $g_{\text{eff}}^2 \ll 1$ which means that $U >> (g_{YM}^2 N)^{1/(3-p)}$ for $p < 3$ and $U << (g_{YM}^2 N)^{(3-p)}$ for $p > 3$. In the ultraviolet limit $U \to \infty$ the string coupling vanish for $p < 3$ and the theory is UV free. In the other case a dual description is needed, which is in accordance with the fact that the corresponding SYM theories are not renormalizable and new degrees of freedom appears at short distances.

The situation is different for $p = 3$, in which the AdS/CFT correspondence fully applies. The type IIB supergravity solutions of the form

$$g_{10} = H^{-1/2} (-dt^2 + dx^2 + dy^2 + dz^2) + H^{1/2} (dr^2 + r^2 g_5),$$

$$e^{2\phi} = e^{2\phi_\infty}, \quad F_5 = (1 + \ast) dH^{-1} \wedge dx^0 \wedge dx^1 \wedge dx^2 \wedge dx^3,$$

being $H(r)$ an harmonic function over the Ricci flat metric given by

$$H(r) = 1 + \frac{L^4}{r^4}, \quad L^4 = 4\pi g_s N \alpha^2.$$
from the curvature in the near horizon limit is $R \sim 1/g_{\text{eff}}$ which is $U$ dependent, thus no AdS factor appears. This reflects that $U(N_c)$ super Yang Mills theory is not conformal invariant. The same happen for non flat branes.

There are also of interest eleven dimensional supergravity solutions over a manifold with local form $M_3 \times X_8$, being the manifold $X_8$ Ricci-flat and developing a conical singularity. The generic supergravity solution in consideration is of the form

$$g_{11} = H^{-2/3}(-dt^2 + dx^2 + dy^2) + H^{1/3}(dr^2 + r^2 g_7) , \quad (4.108)$$

where

$$H(r) = 1 + \frac{25\pi^2 N l_p^6}{r^6}.$$  

This solution describe $N$ M2 branes. The near horizon limit of this geometry is obtained taking the 11 dimensional Planck length $l_p \to 0$ and keeping fixed $U = r^2/l_p^3$. The resulting background is $AdS_4 \times X_7$, being $X_7$ is an Einstein manifold with cosmological constant $\Lambda = 5$, and the radius of $AdS_4$ is $2R_{AdS} = l_p(25\pi^2 N)^{1/6}$. Such solutions have the generic form

$$g_{11} = g_{AdS} + g_7, \quad F_4 \sim \omega_{AdS} , \quad (4.109)$$

being $\omega_{AdS}$ the volume form of $AdS_4$. If $X_7$ is the round sphere the radius will be the same than the $AdS$ part. This is the flat case and it is conjectured that the dual theory is the 2+1 dimensional $N = 8$ superconformal field theory living on the $M2$ brane. The isometry group $SO(7)$ of the sphere reflects the fact that a $N = 8$ SCFT is invariant under $SO(7)$ subgroup instead of $SO(8)$. The quantization of the flux of the tensor $F$ implies that the constant $\alpha$ is quantized in units of $l_{11}^6$, being $l_{11}$ the Planck length in eleven dimensions. This backgrounds are in general associated to three dimensional conformal field theories arising as the infrared limit of the world volume theory of $N$ coincident M2 branes located a the singularity of $M_3 \times X_8$. Also in this case, the number of supersymmetries of the field theory is determined by the holonomy of $X_8$. In the case of $Spin(7)$, $SU(4)$ or $Sp(2)$ holonomies we have $N = 1, 2, 3$ supersymmetries, respectively. This implies that the 7-dimensional cone will be of weak $G_2$ holonomy (if the eight dimensional metric is of cohomogeneity one, see below), tri-Sassaki or a Sasaki-Einstein, respectively. If $g_8$ is flat, then we have the maximal number of supersymmetries, namely eight.

### 4.4 Supergravity backgrounds over tri-Sassaki and weak $G_2$

Let us construct supergravity backgrounds corresponding to the Einstein 7-metrics (4.104) or (4.97), (4.99) and (4.100). The generic 11-dimensional supergravity solution is

$$g_{11} = H^{-2/3}(-dt^2 + dx^2 + dy^2) + H^{1/3}(dr^2 + r^2 g_7 + (g_7)_{\alpha \phi} d\alpha \otimes d\phi + (g_7)_{\beta \phi} d\beta \otimes d\phi + (g_7)_{\alpha \beta} d\alpha \otimes d\beta + (g_7)_{\beta \beta} d\beta^2 + (g_7)_{\alpha \phi} d\phi^2 + Q_\alpha d\alpha + Q_\beta d\beta + Q_\phi d\phi + \tilde{H}) , \quad (4.108)$$

where

$$H(r) = 1 + \frac{25\pi^2 N l_p^6}{r^6}.$$  

This solution describe $N$ M2 branes. The near horizon limit of this geometry is obtained taking the 11 dimensional Planck length $l_p \to 0$ and keeping fixed $U = r^2/l_p^3$. The resulting background is $AdS_4 \times X_7$, being $X_7$ is an Einstein manifold with cosmological constant $\Lambda = 5$, and the radius of $AdS_4$ is $2R_{AdS} = l_p(25\pi^2 N)^{1/6}$. Such solutions have the generic form

$$g_{11} = g_{AdS} + g_7, \quad F_4 \sim \omega_{AdS} , \quad (4.109)$$

being $\omega_{AdS}$ the volume form of $AdS_4$. If $X_7$ is the round sphere the radius will be the same than the $AdS$ part. This is the flat case and it is conjectured that the dual theory is the 2+1 dimensional $N = 8$ superconformal field theory living on the $M2$ brane. The isometry group $SO(7)$ of the sphere reflects the fact that a $N = 8$ SCFT is invariant under $SO(7)$ subgroup instead of $SO(8)$. The quantization of the flux of the tensor $F$ implies that the constant $\alpha$ is quantized in units of $l_{11}^6$, being $l_{11}$ the Planck length in eleven dimensions. This backgrounds are in general associated to three dimensional conformal field theories arising as the infrared limit of the world volume theory of $N$ coincident M2 branes located a the singularity of $M_3 \times X_8$. Also in this case, the number of supersymmetries of the field theory is determined by the holonomy of $X_8$. In the case of $Spin(7)$, $SU(4)$ or $Sp(2)$ holonomies we have $N = 1, 2, 3$ supersymmetries, respectively. This implies that the 7-dimensional cone will be of weak $G_2$ holonomy (if the eight dimensional metric is of cohomogeneity one, see below), tri-Sassaki or a Sasaki-Einstein, respectively. If $g_8$ is flat, then we have the maximal number of supersymmetries, namely eight.
\[ F = \pm dx \wedge dy \wedge dt \wedge dH^{-1} \]  
(4.110)

being \( H \) an harmonic function over the hyperKahler cone. In particular if \( H = H(r) \) we have

\[ H(r) = 1 + \frac{2^5 \pi^2 N l_p^6}{r^6}. \]  
(4.111)

In the expression for the metric we have introduced the 1-forms \( Q \) and the symmetric tensor \( \tilde{H} \) given by

\[ \tilde{H} = d\theta^2 + d\varphi^2 + (g_{\theta\eta}d\theta \otimes d\eta + (g_{\rho\rho})d\rho \otimes d\eta + (g_{\eta\eta})d\eta^2; \]

\[ Q_\alpha = (g_{\alpha \theta})d\theta + (g_{\alpha \varphi})d\varphi, \quad Q_\beta = (g_{\beta \varphi})d\varphi, \quad Q_\phi = (g_{\phi \varphi})d\varphi + (g_{\phi \eta})d\eta + (g_{\phi \rho})d\rho. \]

This supergravity solution describes \( N \) M2 branes. The near horizon limit of this geometry is obtained taking the 11 dimensional Planck length \( l_p \rightarrow 0 \) and keeping fixed \( U = r^2/l_p^3 \).

The resulting background is \( AdS_4 \times X_7 \), being \( X_7 \) is an Einstein manifold with cosmological constant \( \Lambda = 5 \), and the radius of \( AdS_4 \) is \( 2R_{AdS} = l_p(2^5 \pi^2 N)^{1/6} \). Such solutions have the generic form

\[ g_{11} = g_{AdS} + g_7, \quad F_4 \sim \omega_{AdS}, \]  
(4.112)

being \( g_7 \) an Einstein metric over \( X_7 \) and \( \omega_{AdS} \) the volume form of \( AdS_4 \).

**Non AdS backgrounds and harmonic functions**

Non AdS backgrounds are also of interest because they are related to non conformal field theories. Therefore it is of interest to find harmonic functions with are functions not only of the radius \( r \), but also of other coordinates of the internal space.

We will now give here a simple way to construct non trivial harmonic functions. Let us notice that all the 4-dimensional quaternion Kahler orbifolds that we have constructed have two commuting Killing vectors which also preserve the one forms \( \omega^i \). This vector also preserve the Kahler triplet \( d\bar{J} = d\omega_- + \omega_- \wedge \omega_- \). Consequently they preserve the hyperKahler triplet \( (2,31) \) for the corresponding Swann fibration. Such vectors are therefore Killing and tri-holomorphic (thus tri-hamiltonian). For any eight dimensional hyperKahler metric with two commuting Killing vectors there exist a coordinate system in which takes the form \( [35] \)

\[ g_8 = U_{ij}dx^i \cdot dx^j + U^{ij}(dt_i + A_i)(dt_j + A_j), \]  
(4.113)

being \( (U_{ij}, A_i) \) solutions of the generalized monopole equation

\[ F_{x^i \bar{x}^j} = \epsilon_{\mu\nu\lambda} \nabla_{x^i} U_j, \]
\[ \nabla_{x^i} U_j = \nabla_{x^j} U_i, \]
\[ U_i = (U_{i1}, U_{i2}), \]  
(4.114)
The coordinates \((x_1^2, x_2^2)\) with \(i = 1, 2, 3\) are the momentum maps of the tri-holomorphic vector fields \(\partial/\partial \theta\) and \(\partial/\partial \phi\), but we do not need to go in further details. In the momentum map system the 11-dimensional supergravity solution reads
\[
g_{11} = H^{-2/3}g_{2,1} + H^{1/3}[U_{ij}dx^i \cdot dx^j + U^{ij}(dt_i + A_i)(dt_j + A_j)],
\]
\[
F = \pm \omega (E^{2,1}) \wedge dH^{-1},
\]
and the harmonic condition on \(H\) is expressed as
\[
U^{ij} \partial_i \cdot \partial_j H = 0.
\]
All the Swann hyperKahler cones that we have presented are toric, and therefore they can be expressed as
\[
g_8 = dr^2 + r^2g_7 = U_{ij}dx^i \cdot dx^j + U^{ij}(dt_i + A_i)(dt_j + A_j)
\]
Let us recall that, as a consequence of (4.114), we have that \(U^{ij}\partial_i \cdot \partial_j U_{ij} = 0\), which implies that \(U^{ij}\partial_i \cdot \partial_j U_{ij} = 0\). This means that any entry \(U_{ij}\) is an harmonic function over the hyperKahler cone. The matrix \(U^{ij}\) is determined by the relation \(U^{ij} = g_8(\partial_i, \partial_j)\), and the inverse matrix \(U_{ij}\) will give us three independent non trivial harmonic functions for the internal space in consideration.

As an example we can consider the cone \(g_8 = dr^2 + r^2g_7\) the tri-Sasaki metric corresponding to the AdS-Taub-Nut solution [4.97]. For this cone we have that
\[
U^{\tilde{\mu}} = r^2(\tilde{r} - N)^2 + r^2V(\tilde{r}), \quad U^{\tilde{\phi}} = 4\tilde{N}r^2V(\tilde{r})\cos^2 \tilde{\theta} + (\tilde{r}^2 - N^2)r^2 \sin^2 \tilde{\theta}
\]
\[
U^{\tilde{t}\phi} = -2Nr^2V(\tilde{r})\cos \tilde{\theta} + r^2(\tilde{r} - N)g(\tilde{r})\cos \tilde{\theta}.
\]
By defining \(\Delta = U^{\tilde{\mu}}U^{\tilde{\phi}} - (U^{\tilde{t}\phi})^2\) we obtain the following harmonic functions
\[
U_{\tilde{\mu}} = \frac{U^{\tilde{\phi}}}{\Delta}, \quad U_{\tilde{\phi}} = -\frac{U^{\tilde{\mu}}}{\Delta}, \quad U_{\tilde{t}\phi} = \frac{U^{\tilde{t}\phi}}{\Delta}.
\]
In the \(S^4\) manifold limit we obtain more simple expressions, namely
\[
U_{\tilde{\phi}} = \frac{1}{r^2}\left(\frac{1}{\sin^2 \tilde{\theta} + \sin^2 \tilde{\rho} \cos^2 \tilde{\theta} - \sin^4 \tilde{\rho} \cos^2 \tilde{\theta}}\right)
\]
\[
U_{\tilde{\phi}t} = \frac{1}{r^2}\left(\frac{\sin^2 \tilde{\theta} + \sin^2 \tilde{\rho} \cos^2 \tilde{\theta}}{\sin^2 \tilde{\theta} + \sin^2 \tilde{\rho} \cos^2 \theta - \sin^4 \tilde{\rho} \cos^2 \tilde{\theta}}\right)
\]
\[
U_{\tilde{\mu}} = \frac{1}{r^2}\left(\frac{\sin^2 \tilde{\rho} \cos \tilde{\theta}}{\sin^2 \tilde{\theta} + \sin^2 \tilde{\rho} \cos \theta - \sin^4 \tilde{\rho} \cos \theta}\right)
\]
For the AdS-Kerr-Newman case [4.99] we have
\[
U^{\tilde{\mu}} = r^2 \left(\frac{c(\tilde{r})d(\tilde{r})}{r^2 - a^2 \cos \tilde{\theta}^2} + a^2r^2 \frac{f(\tilde{\theta}) \sin^2 \tilde{\theta}}{r^2 - a^2 \cos^2 \theta} + r^2e^2(\tilde{r}, \tilde{\theta})\right),
\]
the tensor fields $M$ (5.133) possess a manifest $SL(U$ gravity with field theories in [12]. One usually starts with a solution of the eleven dimensional super-introduction. This technique was applied in order to find the dual of marginal deformed generic form $D\alpha$ derivative run over the remaining eight dimensional coordinates. We have introduced the covariant $C$ and the field $5.1$ Deformations of 11-supergravity solutions

5. Gamma deformations of supergravity backgrounds

5.1 Deformations of 11-supergravity solutions

Let us describe in more detail the $SL(2, R)$ solution generating technique sketched in the introduction. This technique was applied in order to find the dual of marginal deformed field theories in [12]. One usually starts with a solution of the eleven dimensional supergravity with $U(1) \times U(1) \times U(1)$ isometry. Any of such solutions can be written in the generic form

$$g_{11} = \Delta^{1/3} M_{ab} D\alpha_a D\alpha_b + \Delta^{-1/6} g_{\mu\nu} dx^\mu dx^\nu,$$

$$C_3 = CD\alpha_1 \wedge D\alpha_2 \wedge D\alpha_3 + C_{1(ab)} \wedge D\alpha_a \wedge D\alpha_b + C_{2(a)} \wedge D\alpha_a + C_{(3)},$$

with the indices $a,b=1,2,3$ are associated to three coordinates $\alpha_1, \alpha_2$ and $\alpha_3$. The metric and the field $C_3$ does not depend on these coordinates and the greek indices $\mu, \nu$ run over the remaining eight dimensional coordinates. We have introduced the covariant derivative $D\alpha_i = d\alpha_i + A_i$, being $A_i$ a triplet of $\alpha_i$-independent one forms. The expression (5.133) possess a manifest $SL(3, R)$ symmetry for which the coordinates $\alpha_i$ of (5.133) and the tensor fields $M$ and $A_i$ have the following transformation law

$$\begin{pmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{pmatrix} \rightarrow (\Lambda^T)^{-1} \begin{pmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{pmatrix}, \tag{5.122}$$

$$M' = \Lambda M \Lambda^T \begin{pmatrix} A_1 \\ A_2 \\ A_3 \end{pmatrix} \rightarrow (\Lambda^T)^{-1} \begin{pmatrix} A_1 \\ A_2 \\ A_3 \end{pmatrix}. \tag{5.123}$$

$$\begin{pmatrix} C_{23\mu} \\ C_{31\mu} \\ C_{12\mu} \end{pmatrix} \rightarrow (\Lambda^T)^{-1} \begin{pmatrix} C_{23\mu} \\ C_{31\mu} \\ C_{12\mu} \end{pmatrix}, \quad \begin{pmatrix} C_{1\mu\nu} \\ C_{2\mu\nu} \\ C_{3\mu\nu} \end{pmatrix} \rightarrow \Lambda \begin{pmatrix} C_{1\mu\nu} \\ C_{2\mu\nu} \\ C_{3\mu\nu} \end{pmatrix}. \tag{5.124}$$
The full isometry group of 11-dimensional supergravity compactified on a three torus is \( SL(3, R) \times SL(2, R) \). The \( SL(3, R) \) group leaves the background \((5.133)\) unaltered. Following [12] and [108] we will deform these \( T^3 \) invariant backgrounds by an element of \( SL(2, R) \). These deformation is a solution generating technique which does not leave the background unchanged, but gives new supergravity backgrounds. We find convenient to define a complex parameter \( \tau = C + i\Delta^{1/2} \) which, under the \( SL(2, R) \) action is transformed as

\[
\tau \rightarrow \frac{a\tau + b}{c\tau + d}; \quad \Lambda = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL(2, R). \tag{5.124}
\]

The eight dimensional metric \( g_{\mu\nu} \) and the tensor \( C^2 \) are invariant under this action. The tensor \( C^{(1)ab} \) and \( A_{a} \) form a doublet in similar way that the RR and NSNS two form fields do in IIB supergravity, their transformation law is

\[
B^a = \begin{pmatrix} 2A_a \\ -e^{abc}C_{(1)bc} \end{pmatrix}, \quad B_a \rightarrow \Lambda^{-T}B_a. \tag{5.125}
\]

The field strength \( C_3 \) also form a doublet with its magnetic dual with transformation law

\[
H = \begin{pmatrix} F_4 \\ \Delta^{-1/2} *_8 F_4 + C_{(0)}F_4 \end{pmatrix}, \quad H \rightarrow \Lambda^{-T}H, \tag{5.126}
\]

being the Hodge operation taken with respect to the eight dimensional metric \( \tilde{g} \). As we discussed in the introduction, this transformation deform the original metric \((5.133)\) and the deformed metric will be regular only with elements of the form [12]

\[
\Lambda = \begin{pmatrix} 1 & 0 \\ \gamma & 1 \end{pmatrix} \in SL(2, R), \tag{5.127}
\]

which constitute a subgroup called \( \gamma \)-transformations. We will be concerned with such transformations in the following.

If the fields \( C, C_1 \) and \( C_2 \) are zero, it follows that \( A_i \) and \( \tilde{g}_{\mu\nu} \) are unchanged by a \( \gamma \)-transformation and \( C_1 \) and \( C_2 \) remains zero. The deformation then give the new fields

\[
\Delta' = G^2\Delta, \quad C' = -\gamma G\Delta, \quad G = \frac{1}{1 + \gamma^2\Delta}. \tag{5.128}
\]

By inspection of the transformation rule \((5.126)\) it follows that

\[
F_4' = F_4 - \gamma \Delta^{-1/2} *_8 F_4 - \gamma d(G\Delta D\alpha_1 \wedge D\alpha_2 \wedge D\alpha_3). \tag{5.129}
\]

The \( \gamma \)-deformed eleven dimensional metric results [108]

\[
g_{11} = G^{-1/3}(G^{1/3}M_{ab}D\alpha_1 D\alpha_2 + \Delta^{-1/6}\tilde{g}_{\mu\nu}dx^\mu dx^\nu). \tag{5.130}
\]

Note that if the initial four form \( F_4 \) was zero, then from the last term in \((5.129)\) a non trivial flux is obtained in the deformed background.
5.2 A family of deformed backgrounds

As we have already mentioned, any eight-dimensional Ricci flat metric $g_8$ can be extended to an eleven dimensional supergravity solution of the form

$$g_{11} = H^{-2/3}(-dt^2 + dx^2 + dy^2) + H^{1/3}g_8$$

$$C^3 = \pm H^{-1}dx \wedge dy \wedge dt, \quad F^4 = \pm dx \wedge dy \wedge dt \wedge dH^{-1},$$

being $H$ an harmonic function over $g_8$. If the metric $g_8$ is a cone then we can reexpress the eleven dimensional metric as

$$g_{11} = H^{-2/3}(-dt^2 + dx^2 + dy^2) + H^{1/3}(dr^2 + r^2g_7)$$

being $g_7$ an Einstein metric. If $g_8$ is hyperKahler then $g_7$ will be tri-Sasaki, if $g_8$ is of $\text{Spin}(7)$ holonomy with cohomogeneity one, then $g_7$ will be of weak $G_2$ holonomy. We have constructed a whole family of tri-Sasaki metrics in (4.97), (4.99) and (4.100). In addition, the replacement $g_q \to 5g_q$ in all these expressions give a family of metrics with weak $G_2$ holonomy. All these metrics possess three commuting Killing vectors, namely $\partial_r$, $\partial_\alpha$ and $\partial_\beta$. Therefore they are suitable to apply the $SL(2, R)$ solution generating technique described previously. The corresponding 11-dimensional supergravity background with three commuting isometries is

$$g_{11} = H^{-2/3}(-dt^2 + dx^2 + dy^2) + H^{1/3}r^2\left((g_7)_{\bar{\tau}t}d\bar{t}^2 + (g_7)_{\bar{\tau}\phi}d\bar{t} \otimes d\bar{\phi} + (g_7)_{\bar{\tau}r}d\bar{t} \otimes dr + (g_7)_{\tau\phi}d\phi \otimes d\bar{t} + (g_7)_{\tau r}dr \otimes d\bar{t} + Q_t d\bar{t} + Q_\phi d\bar{\phi} + Q_r dr + \tilde{H}\right),$$

$$C^3 = \pm H^{-1}dx \wedge dy \wedge dt, \quad F^4 = \pm dx \wedge dy \wedge dt \wedge dH^{-1}, \quad \text{(5.131)}$$

where we have defined

$$Q_t = (g_7)_{\bar{\tau}t}d\bar{\tau}, \quad Q_\phi = (g_7)_{\bar{\tau}\phi}d\bar{\tau}, \quad Q_r = (g_7)_{\tau r}d\tau, \quad \text{(5.132)}$$

$$\tilde{H} = dr^2 + d\phi^2 + (g_7)_{\bar{\tau}\phi}d\bar{\tau} \otimes d\bar{\phi} + (g_7)_{\bar{\tau}r}d\bar{\tau} \otimes dr + (g_7)_{\tau \phi}d\phi \otimes d\bar{\tau} + (g_7)_{\tau r}d\tau \otimes d\phi + g_{\bar{\tau}\phi}d\bar{\tau} \otimes d\bar{\phi}$$

Under the replacement $g_q \to 5g_q$ we will obtain a new supergravity solution which is fibered over a weak $G_2$ holonomy space. The solution generating technique applies to both cases exactly in the same manner, but the dual field theories will possess different number of supercharges. Let us note that if the harmonic function is selected to be

$$H(r) = 1 + \frac{2^5 \pi^2 N l_p^6}{r^6}.$$

then the near horizon limit will be

$$g_{11} = g_{AdS} + g_7.$$
But we can consider backgrounds with other horizon limits by considering harmonic functions such as those constructed in (4.117)-(4.120).

Our task now is to find a local coordinate system for which (5.131) takes the manifest $T^3$ symmetric form

$$g_{11} = \Delta^{1/3} M_{ab} D_\phi_a D_\phi_b + \Delta^{-1/6} \tilde{g}_{\mu\nu} dx^\mu dx^\nu$$

(5.133)

with the indices $a,b=1,2,3$ are associated to the isometries $\phi_1 = \tilde{t}$, $\phi_2 = \tilde{\phi}$ and $\phi_3 = \tau$ and the greek indices $\mu, \nu$ running over the remaining eight dimensional coordinates. We need to introduce the following quantities

$$h = \tilde{H} - r^2 H^{1/3} (g_7)_{ab} A_a A_b$$

(5.134)

With the help of these quantities it is not difficult to check that the metric takes the form

$$g_{11} = g_8 + H^{1/3} r^2 (g_7)_{ab} (d\phi_a + A_a) (d\phi_b + A_b)$$

being $g_8$ given by

$$g_8 = H^{-2/3} (-dt^2 + dx^2 + dy^2) + H^{1/3} (dr^2 + r^2 h).$$

(5.135)

By further defining

$$\Delta = [\det \Omega^{ab}], \quad \bar{g} = \Delta^{1/6} g_8,$$

$$D_\phi_a = d\phi_a + A_a, \quad \Omega^{ab} = r^2 H^{1/3} (g_7)_{ab} \quad M_{ab} = \frac{\Omega^{ab}}{\det(\Omega^{ab})^{1/3}}.$$ (5.136)

the metric takes the desired form with manifest $SL(3, R)$ symmetry

$$g_{11} = \Delta^{1/3} M_{ab} D_\phi_a D_\phi_b + \Delta^{-1/6} \bar{g}_{\mu\nu} dx^\mu dx^\nu,$$

(5.137)

By using these quantities together with formulas (5.128)-(5.130) we obtain the following the deformed backgrounds.

For the orbifolds (4.103) we have that

$$Q_\alpha = (g_7)_{\alpha \beta} d\theta + (g_7)_{\alpha \varphi} d\varphi, \quad Q_\beta = (g_7)_{\beta \varphi} d\varphi, \quad Q_\varphi = (g_7)_{\varphi \varphi} d\varphi, \quad Q_\theta = (g_7)_{\theta \varphi} d\varphi + (g_7)_{\varphi \theta} d\eta + (g_7)_{\varphi \varphi} d\rho,$$

$$\tilde{H} = d\theta^2 + d\varphi^2 + (g_7)_{\theta \theta} d\theta \otimes d\theta + (g_7)_{\varphi \varphi} d\varphi \otimes d\eta + (g_7)_{\varphi \varphi} d\rho \otimes d\eta + (g_7)_{\eta \eta} d\eta^2.$$ (5.138)

The explicit form of the matrix $\Omega_{ab}$ turns out to be

$$\Omega_{ab} = r^2 H^{1/3} \begin{pmatrix}
1 & -\frac{2\sqrt{F}}{r^2} \sin \theta \cos \varphi + \frac{2n}{\sqrt{F}} \cos \theta & -\frac{2\sqrt{F}}{r^2} \cos \theta \\
-\frac{2\sqrt{F}}{r^2} \sin \theta \cos \varphi + \frac{2n}{\sqrt{F}} \cos \theta & (g_q)_{\alpha\alpha} + \frac{(1+\rho^2)}{\rho^2} & (g_q)_{\alpha\beta} + \frac{2n}{\rho^2} \\
-\frac{2\sqrt{F}}{r^2} \cos \theta & (g_q)_{\alpha\beta} + \frac{2n}{\rho^2} & (g_q)_{\beta\beta} + \frac{2n}{\rho^2}
\end{pmatrix},$$

being $g_q$ the quaternion Kahler metric defined in (3.68). All these quantities are expressed in terms of a single eigenfunction $F$ of the laplacian operator in the hyperbolic two dimensional space. By using the formulas (5.128), (5.129) and (5.130) we obtain directly the deformed backgrounds, as before.
5.3 Explicit formulas for the spherical case

It will be instructive to repeat this procedure to the background \([5.151]\) fibered over \(S^4\). We need to define the relevant quantities first. From the definition \(\Omega^{ab} = g_{ab}\) being \(a, b = 1, 2, 3\) and \(\phi_1 = \tilde{t}, \phi_2 = \tilde{\phi}\) and \(\phi_3 = \tau\), we find the following toric fiber metric

\[
\Omega^{\tilde{t}t} = \Omega^{\tilde{\phi}\phi} = \Omega^{\tau\tau} = 1, \quad \Omega^{\tilde{t}\phi} = \sin \tilde{\rho} \cos \tilde{\theta},
\]

\[
\Omega^{\tilde{t}\tau} = -\sin \tilde{\rho} \sin \theta \cos \varphi, \quad \Omega^{\phi\tau} = -\sin \theta (\sin \varphi \cos \tilde{\rho} \sin \tilde{\theta} + \cos \varphi \cos \tilde{\theta}). \tag{5.139}
\]

The determinant \(\Delta = \det \Omega^{ab}\) of this matrix is

\[
\Delta = -\sin \tilde{\rho} \sin \theta \cos \varphi \left[ \sin \tilde{\rho} \cos \tilde{\theta} \sin \theta (\sin \varphi \cos \tilde{\rho} \sin \tilde{\theta} + \cos \varphi \cos \tilde{\theta}) + \sin \tilde{\rho} \sin \theta \cos \varphi \right] + [1 - \sin^2 \theta (\sin \varphi \cos \tilde{\rho} \sin \tilde{\theta} + \cos \varphi \cos \tilde{\theta})^2] - \sin \tilde{\rho} \cos \tilde{\theta} (\sin \tilde{\rho} \cos \tilde{\theta} + \sin \tilde{\rho} \sin \theta \cos \varphi). \tag{5.140}
\]

From \((5.139)\) and \((5.140)\) we define the matrix \(M_{ab} = \Omega^{ab} / \Delta^{1/3}\) with unit determinant. Also, from the definition \(\Omega_{ab} = g^{ab}\) of the inverse matrix we obtain that

\[
\Omega_{tt} = \frac{1}{\Delta} \left( 1 - \sin^2 \theta (\sin \varphi \cos \tilde{\rho} \sin \tilde{\theta} + \cos \varphi \cos \tilde{\theta})^2 \right),
\]

\[
\Omega_{t\phi} = \frac{1}{\Delta} \left( 1 + \sin^2 \tilde{\rho} \sin^2 \theta \cos^2 \varphi \right), \quad \Omega_{t\tau} = \frac{1}{\Delta} \left( 1 - \sin^2 \tilde{\rho} \cos^2 \tilde{\theta} \right),
\]

\[
\Omega_{\phi\phi} = \frac{1}{\Delta} \left( \sin \tilde{\rho} \cos \tilde{\theta} - \sin^2 \theta \sin \tilde{\rho} \cos \varphi (\sin \varphi \cos \tilde{\rho} \sin \tilde{\theta} + \cos \varphi \cos \tilde{\theta}) \right), \tag{5.141}
\]

\[
\Omega_{\phi\tau} = \frac{1}{\Delta} \left( \sin \theta \sin \tilde{\rho} \cos \varphi - \sin \tilde{\rho} \cos \tilde{\theta} \sin \theta (\sin \varphi \cos \tilde{\rho} \sin \tilde{\theta} + \cos \varphi \cos \tilde{\theta}) \right),
\]

\[
\Omega_{\tau\tau} = \frac{1}{\Delta} \left( \sin \theta \sin^2 \tilde{\rho} \cos \tilde{\theta} \cos \varphi - \sin \theta (\sin \varphi \cos \tilde{\rho} \sin \tilde{\theta} + \cos \varphi \cos \tilde{\theta}) \right).
\]

The one forms \(Q_i\) are

\[
Q_t = \sin \tilde{\rho} \sin \varphi d\theta, \quad Q_\phi = (\cos \tilde{\theta} \sin \varphi - \cos \tilde{\rho} \sin \tilde{\theta} \cos \varphi) d\theta
\]

\[
Q_\tau = -\cos \theta (d\varphi + \cos \tilde{\rho} d\tilde{\theta}) \tag{5.142}
\]

With the help of \((5.141)\) and \((5.142)\) we define the one forms \(A_a\) and the covariant derivative \(D_a\) by

\[
A_a = \Omega_{ab} Q_b, \quad D_a = d\phi_a + A_a. \tag{5.143}
\]

The metric \(\tilde{H}\) defined in \((5.132)\) is

\[
\tilde{H} = d\theta^2 + d\varphi^2 + d\tilde{\rho}^2 + d\tilde{\theta}^2 - 2 \cos \tilde{\rho} d\tilde{\theta} \otimes d\varphi, \tag{5.144}
\]

and therefore the metric in \((5.136)\) reads

\[
h = \tilde{H} - (g_\tau)_{ab} A_a A_b. \tag{5.145}
\]
With the help of formulas (5.133)-(5.137) we obtain the deformed background, the result is
\[ g_d = (1 + \gamma^2 \Delta)^{1/3} \left( g_{11} - \frac{\gamma^2 \Delta}{1 + \gamma^2 \Delta} \Omega_{ab} Q_a Q_b \right) \] (5.146)

\[ C = -\frac{k \sin u}{3} \sinh^3 \rho dt \wedge du \wedge dv - \frac{\gamma \Delta}{1 + \gamma^2 \Delta} D\tilde{t} \wedge D\tilde{\phi} \wedge D\tau, \]

being \( g_{11} \) the undeformed metric (5.151). Notice that (5.146) is explicit because all the quantities are defined by (5.140), (5.141) and (5.142). The procedure is completed.

We will consider IIB reductions of these backgrounds and their deformations in the appendix.

5.4 Rotating supermembrane solutions

We have presented an infinite family of eleven dimensional supergravity backgrounds possessing at least three commuting Killing vectors. These backgrounds are supposed to be dual to three dimensional conformal field theories arising as the infrared limit of the world volume theory of \( N \) coincident M2 branes located at a the singularity of \( M_3 \times X_8 \).

Because the eight dimensional geometry is hyperKahler we expect \( N = 3 \) supersymmetry in the superconformal field theory. But it is difficult to guess which is the explicit form of the dual field theory and we are no attempting to obtain an explicit lagrangian here. Nevertheless it has been suggested that the correspondence between semiclassical strings with high angular momentum and long operators can be generalized to membranes [20]. In the string case the configurations have energy proportional to the T Hooft scale and thus are dual to operators with large dimensions [7]. For a rotating string in \( AdS_5 \) the difference between the energy and the spin depends logarithmically on the spin, therefore the dual operators should possess dimensions with the same dependence. This operators are twist operators that are responsible for violations of Bjorken scaling, and it has been shown that no corrections to the logarithmic behaviour appears in the strong coupling limit [8]. This correspondence have been generalized to membranes, in which the relation between the spin, the J-charges and the energy should be related to the anomalous dimensions of certain operators of the conformal field theory [20].

Therefore it is of interest to consider rotating membrane configurations over the supergravity backgrounds that we have constructed. Recall that the supermembrane action is given by
\[ S = -\frac{1}{2\pi^2 l_1^3} \int \left( \frac{(-\gamma)^{1/2}}{2} \left[ \gamma_{ij} \frac{\partial X_\mu}{\partial \sigma_i} \frac{\partial X_\nu}{\partial \sigma_j} G_{\mu\nu} - 1 \right] + \epsilon_{ijk} \frac{\partial X_\nu}{\partial \sigma_i} \frac{\partial X_\mu}{\partial \sigma_j} \frac{\partial X_\nu}{\partial \sigma_k} C_{\mu\nu\rho} \right) d^3\sigma \] (5.147)

where \( \sigma_i = (\tau, \sigma, \lambda) \) are the world volume coordinates, \( \gamma_{ij} \) the worldvolume metric, \( X_\mu \) are the then target space coordinates and \( G_{\mu\nu} \) the target metric. We have also the 3-form \( C_{\mu\nu\rho} \) and the corresponding field strength is \( H = dC \). The equations of motion derived from (5.147) is
\[ \gamma_{ij} = \partial_i X_\mu \partial_j X_\nu G_{\mu\nu} \] (5.148)
\[
\partial_i \left( (-\gamma)^{1/2} \epsilon^{ij} \partial_j X^\rho \right) = -(-\gamma)^{1/2} \epsilon^{ij} \partial_i X^\mu \partial_j X^\nu \Gamma^\rho_{\mu
u}(X) - \epsilon^{ijk} \partial_i X^\mu \partial_j X^\nu \partial_k X^\sigma H^\rho_{\mu\nu\sigma}(X)
\]

The three diffeomorphisms of the action can be fixed by a gauge described by the constraints
\[
\gamma_{0\alpha} = \partial_0 X^\mu \partial_\alpha X^\nu G_{\mu\nu}(X) = 0,
\]
\[
\gamma_{00} + L^2 \det [\gamma_{\alpha\beta}] = \partial_0 X^\mu \partial_0 X^\nu G_{\mu\nu}(X) + L^2 \det [\partial_\alpha X^\mu \partial_\beta X^\nu G_{\mu\nu}(X)] = 0,
\]
being \(L\) a constant fixed by the equations of motion. By imposing the constraints (5.149) to (5.147) we obtain the following action in gauge fixed form
\[
S = \frac{1}{2(2\pi)^2 L l_{11}^3} \int \left( \partial_0 X^\mu \partial_\alpha X^\nu G_{\mu\nu}(X) - L^2 \det [\partial_\alpha X^\mu \partial_\beta X^\nu G_{\mu\nu}(X)] \right) d^3 \sigma.
\]

In Poincare coordinates the AdS \(_4\) space is parameterized as
\[
g_{AdS} = -\cosh^2 \rho dt^2 + d\rho^2 + \sinh^2 \rho (du^2 + \sin^2 u dv^2).
\]
and the eleven dimensional background becomes
\[
\frac{1}{l_{11}^2} g_{11}^2 = -\cosh^2 \rho dt^2 + d\rho^2 + \sinh^2 \rho (du^2 + \sin^2 u dv^2) + r_{12} g_7,
\]

\[
F_4 = k \cosh \rho \sinh^2 \rho \sin u dt \wedge d\rho \wedge du \wedge dv, \quad C = -\frac{k \sin u}{3} \sinh^3 \rho dt \wedge du \wedge dv,
\]
being \(r_{12}\) the relative radius between the AdS \(_4\) and the internal space and \(k\) is a constant determined by the equation of motions.

We will study now the case when the metric on \(X_7\) is the tri-Sasaki metric fibered over the sphere \(S^4\), the metric is given in (4.100). Our eleven dimensional background is
\[
g_{11} = -\cosh^2 \rho dt^2 + d\rho^2 + \sinh^2 \rho (du^2 + \sin^2 u dv^2)
+ (\cos \bar{\rho} \sin \bar{\theta} \sin \varphi \sin \theta \sin \varphi \sin \theta d\tau)^2 + (\cos \bar{\rho} \sin \bar{\theta} \sin \varphi \sin \theta d\tau)^2 + (\cos \bar{\rho} \sin \bar{\theta} \sin \varphi \sin \theta d\tau)^2 + (\cosh \varphi \sin u dt^2 + \sinh \varphi (du^2 + \sin^2 u dv^2))^2 + \sin^2 \bar{\theta} d\phi^2 + \sin^2 \bar{\phi} d\bar{\theta}^2)
\]

The first configuration is one rotating in the AdS background and for which the third direction is wrapped in the Reeb direction
\[
\rho = \rho(\sigma), \quad t = k\tau, \quad u = \frac{\pi}{2}, \quad v = \omega \tau, \quad \theta = \frac{\pi}{2}, \quad \varphi = \frac{\pi}{2},
\]
\[
\tau = \lambda \delta \quad \bar{\rho} = \frac{\pi}{2}, \quad \bar{\theta} = \frac{\pi}{2}, \quad \bar{\phi} = \nu \bar{\phi}, \quad \bar{t} = \nu \tau.
\]

The second configuration we will analyze is one in which the membrane rotates in the internal space (R-charge) and the third direction is wrapped in AdS, namely
\[
\rho = \rho(\sigma), \quad t = k\tau, \quad u = \frac{\pi}{2}, \quad v = \lambda \delta, \quad \theta = \frac{\pi}{2}, \quad \varphi = \frac{\pi}{2}.
\]
\[
\tau = \nu \tilde{\tau}, \quad \tilde{\rho} = \frac{\pi}{2}, \quad \tilde{\theta} = \frac{\pi}{2}, \quad \tilde{\phi} = \nu \tilde{\phi}, \quad \tilde{t} = \nu \tilde{t}.
\]

For the first configuration by selecting \( L = 1 \) we have that
\[
g_{\mu\nu} \partial_{\sigma} X^\mu \partial_{\tau} X^\nu = g_{\mu\nu} \partial_{\sigma} X^\mu \partial_{\tilde{\tau}} X^\nu = g_{\mu\nu} \partial_{\sigma} X^\mu \partial_{\tilde{\phi}} X^\nu = 0,
\]
\[
g_{\mu\nu} \partial_{\tau} X^\mu \partial_{\tau} X^\nu = -\kappa^2 \cosh^2 \rho + \omega^2 \sinh^2 \rho + \nu^2_\phi + \nu^2_t.
\]
\[
g_{\mu\nu} \partial_{\sigma} X^\mu \partial_{\sigma} X^\nu = (\frac{d\rho}{d\sigma})^2,
\]
and the equations of motion gives the further relation
\[
\frac{d\rho}{d\sigma} = \sqrt{-\kappa^2 \cosh^2 \rho + \omega^2 \sinh^2 \rho + \nu^2_\phi + \nu^2_t}.
\]

Inserting this equation into the action give us
\[
S = -P \int d\tilde{\tau} \int_0^{\rho_0} \sqrt{-\kappa^2 \cosh^2 \rho + \omega^2 \sinh^2 \rho + \nu^2_\phi + \nu^2_t} \tag{5.153}
\]

We have that
\[
E = -\frac{\delta S}{\delta k} \sim \int_0^{\rho_0} \frac{\cosh^2 \rho}{\sqrt{-\kappa^2 \cosh^2 \rho + \omega^2 \sinh^2 \rho + \nu^2_\phi + \nu^2_t}},
\]
\[
S = \frac{\delta S}{\delta \omega} \sim \int_0^{\rho_0} \frac{\sinh^2 \rho}{\sqrt{-\kappa^2 \cosh^2 \rho + \omega^2 \sinh^2 \rho + \nu^2_\phi + \nu^2_t}}
\]

But the integral \( (5.153) \) is one of those appearing in [7], and we obtain from here that \( E - S \sim \log S \), which is what we wanted to show.

For the other configuration we have that
\[
S = -P \int d\tilde{\tau} \int_0^{\rho_0} \sinh \rho \sqrt{-\kappa^2 \cosh^2 \rho + \nu^2 + \nu^2_\phi + \nu^2_t} \tag{5.154}
\]

In this case we have no place for spin, in this case we have energy and R-charge angular momentum \( J \)
\[
E = -\frac{\delta S}{\delta k}, \quad J = \frac{\delta S}{\delta \nu}.
\]

From \( (5.154) \) it is obtained that for long membranes, we have \( E = J + \ldots \)

Let us consider now the rotating configuration \( (5.152) \) in the deformed background \( (5.146) \). For this configuration we have that \( \Delta = 1, \Omega^{ab} = 1 \) and \( Q_i \) and \( D^i \wedge D\phi \wedge D\tau \) are zero. This means that the effective metric that the membrane see rotating over \( (5.146) \) or \( (5.151) \) is essentially the same. Thus the logarithmic behaviour of the difference \( E - S \) is reproduced for the deformed background. We find this interesting because, while the undeformed background is a direct product of \( AdS_4 \) with a seven space, the deformation is not.
6. Kahler-Einstein over Kahler-Einstein and other examples

Till the moment have found an explicit expression for Kahler-Einstein metrics defined over the twistor space $Z$ of any four dimensional quaternion Kahler space. We have also have found the corresponding Einstein-Sasski metrics and we have checked, in accordance with [79], that the eight-dimensional cone over them is hyperKahler. It is indeed a Swann metric. Thus such Einstein-Sasaki metrics admit three conformal Killing vectors and are tri-Sasaki. This is different than other Kahler-Einstein spaces appearing in the literature, for which the Einstein-Sasaki metrics admits only two conformal Killing vectors. In this section we review some Kahler-Einstein metrics which are fibered over Kahler metrics of lower dimensions [66]. In general they correspond to Einstein-Sasaki metrics which are not tri-Sasaki. We consider them construction of importance, because they encode several known spaces appearing in the literature.

6.1 The Pedersen-Poon hamiltonian approach

We consider a Kahler space $M$ with metric $g$, a Kahler form $\Omega$ and a complex structure $J$. We assume the presence of $n$ Killing vectors $(X_1,..,X_N)$ for which $\mathcal{L}_{X_i}\Omega = 0$ which means that the generalized torus $T^n$ act through holomorphic isometries over $M$. An holomorphic isometry is also hamiltonian, that is, $\mathcal{L}_{X_i}J = 0$. The Killing vectors are linearly independent in a dense open set of $M$, and are isotropic, that is, $\Omega(X,X) = 0$. This implies that $JX$ is orthogonal to every component of $X$. From the relation

$$\mathcal{L}_{X_i}\Omega = i_{X_i}d\Omega + d(i_{X_i}\Omega) = d(i_{X_i}\Omega) = 0,$$

being $i_{X_i}$ the contraction of the vector field $X_i$ with the two form $\Omega$, it follows the existence of $N$ functions $z_i$, called momentum maps, defined through the relations

$$dz_i = i_{X_i}\Omega. \quad (6.155)$$

The manifold $M$ can be viewed as a torus bundle over a real manifold of dimension $2m - N$, being $m$ the complex dimension of $M$. By denoting the N fiber coordinates as $(t_1,..,t_N)$ it follows that the metric take the form

$$g = h + w_{ij}dz^i dz^j + (w^{-1})_{ij}(dt_i + \theta_i)(dt_j + \theta_j), \quad (6.156)$$
in the momentum map system, being $\theta_i$ certain 1-forms defined over the base space $h$ of the bundle. The matrix $w_{ij}$ is symmetric and positively definite.

The manifold obtained by quotient of $M$ by the torus $T^N$ is described by the coordinates $z_i$ and other complex coordinates $z_\nu$ with $\nu = 1,..,m - N$. The metric $h$ is $2(m - N)$ dimensional, but depend on the coordinates $z_i$ as evolution parameters. In other words $h$ is the metric on the quotient space of each level set of the momentum maps. Both the
matrix $u$ and the base metric $h$ are in principle $z_i$ dependent and $t_i$ independent. The metric $h$ is Kahler \[75\] and therefore complex, and can be written in complex form

$$h = h_{ab} d\xi^a d\bar{\xi}^b. \quad (6.157)$$

From the definition of $\Omega$ it follows directly that

$$g(JX_i, X_j) = \Omega(X_i, X_j) = dz_i(X_j), \quad (6.158)$$

and therefore

$$-J(dt_i + \theta_i) = w_{ij} dz_j.$$ 

This implies that

$$i(dt_i + \theta_i) + w_{ij} dz_j,$$

are $(0,1)$ type forms. The metric \[6.156\] can be expressed in complex form as

$$g = h_{ab} d\xi^a d\bar{\xi}^b + (w^{-1})_{ij} i[w_{ij} dz_j + i(dt_i + \theta_i)] [w_{ij} dz_j - i(dt_i + \theta_i)], \quad (6.159)$$

and the corresponding Kahler form is

$$\Omega = \Omega_h + dz_i \wedge (dt_i + \theta_i). \quad (6.160)$$

From the fact that $\Omega$ is closed, it is obtained a differential system involving $u$, the Kahler metric $h_{ab}$ and $\theta_i$. The resulting equation is

$$d\theta_k = i \partial h_{ab} / \partial z_k d\xi^a \wedge d\bar{\xi}^b + i \partial w_{kl} / \partial \xi^k dz^j \wedge d\xi^k - i \partial w_{kl} / \partial \bar{\xi}^k dz^j \wedge d\bar{\xi}^k, \quad (6.161)$$

and the integrability condition $d(d\theta_k) = 0$ is equivalent to the equation

$$\partial^2 h_{ab} / \partial z_i \partial z_j + \partial^2 w_{ij} / \partial \xi^a \partial \xi^b = 0. \quad (6.162)$$

The constructed metric is Kahler. It will be also Einstein if

$$\rho = \Lambda \Omega \quad (6.163)$$

being $\rho = Ric(J \cdot , \cdot) = -i\partial \bar{\partial} \log \det g$ the Ricci form of the metric $g$, and the scalar curvature will be $2m\Lambda$. The resulting system for Kahler-Einstein metrics was worked out in \[66\]. By defining the function $u$ by

$$u = \log \det h - \log \det w, \quad (6.164)$$

and using that in a Kahler manifold $-i\partial \bar{\partial} = dJd$ it follows that the system \[6.163\] is equivalent to

$$d(Jdu) = A\Omega, \quad (6.165)$$

50
where we have defined $A = -2\Lambda$. By taking into account the expression of $\Omega$ it is obtained from the last condition the following differential system

$$4 \frac{\partial^2 u}{\partial \xi_{\lambda} \partial \xi_{\mu}} + \frac{\partial u}{\partial z_k} (w^{-1})_{kl} \frac{\partial h_{\lambda \mu}}{\partial z_l} = Ah_{\lambda \mu},$$

$$\frac{\partial (\frac{\partial u}{\partial z_k} (w^{-1})_{kl})}{\partial \xi_{\lambda}} = 0, \quad \frac{\partial (\frac{\partial u}{\partial z_k} (w^{-1})_{kl})}{\partial z_i} = A\delta_{il}. $$

The last equation implies that

$$\frac{\partial u}{\partial z_k} (w^{-1})_{kl} = Az_l + B.$$ 

From all this discussion it follows that our toric Kahler-Einstein metrics are described by the system

$$4 \frac{\partial^2 u}{\partial \xi_{\lambda} \partial \xi_{\mu}} + (Az_l + B_l) \frac{\partial h_{\lambda \mu}}{\partial z_l} = Ah_{\lambda \mu}$$

$$\frac{\partial u}{\partial z_k} (w^{-1})_{kl} = Az_l + B_l, \quad (6.166)$$

$$\frac{\partial^2 h_{ab}}{\partial z_i \partial z_j} + \frac{\partial^2 w_{ij}}{\partial \xi^a \partial \xi^b} = 0.$$ 

These equations describe metrics with commuting Killing vectors. But in order to have a free torus action the coordinates $t_k$ should be periodically identified. This is achieved if the closed form

$$d\theta_k = \frac{i}{2} \frac{\partial h_{ab}}{\partial z_k} d\xi^a \wedge d\xi^b + i \frac{\partial w_{kl}}{\partial \xi^k} dz^j \wedge d\xi^k - i \frac{\partial w_{kl}}{\partial \xi^k} dz^j \wedge d\xi^k \quad (6.167)$$

is an integral form for any $k$. In this case there will not be singularities if the coordinate $t_k$ is periodic.

In the $N = 1$ case, that is, when there is only one $U(1)$ holomorphic isometry, the system $(6.166)$ is reduced to

$$4 \frac{\partial^2 u}{\partial \xi_{\lambda} \partial \xi_{\mu}} + (Az + B_l) \frac{\partial h_{\lambda \mu}}{\partial z_l} = Ah_{\lambda \mu}$$

$$\frac{\partial u}{\partial z_k} (w^{-1}) = Az + B, \quad (6.168)$$

$$\frac{\partial^2 h_{ab}}{\partial z^2} + \frac{\partial^2 w}{\partial \xi^a \partial \xi^b} = 0.$$ 

Following [66] it is known that the system can be simplified by imposing that the Kahler quotient metrics obtained from each set of levels are homothetic, that is, $h = f(z)q$ being
the metric $q$ independent on the $z$ coordinate. A further simplification is obtained if the length function $w$ is just a function of $z$. In this case it follows from (6.168) that $f(z) = Cz + D$ being $C$ and $D$ constants, and that

$$-\frac{\partial^2 \log \det q}{\partial \xi_\lambda \partial \xi_\nu} = k q_{\lambda \nu},$$

being the constant $k$ defined by $4k = BC - AD$. This mean that $q$ is also a Kahler-Einstein metric with scalar curvature $4nk$. The class $F_k$ reduce in this case to the Chern form of the Kahler-Einstein base, which takes values $2\pi Z$ for any Kahler-Einstein metric. Thus the metric that we are presenting are defined on a circle bundle. The length function $w$ is obtained from the second (6.166). The result shows that there is no lost of generality in selecting $C = 1$ and $D = 0$, the solution is given by

$$w = \frac{z^n}{pz^{n+2} + qz^{n+1} + s} \quad (6.169)$$

being $p = A/n + 2$, $q = B/n + 1$ and $s$ another constant. The local form of this subfamily of metrics is

$$g' = zq + w dz^2 + \frac{(d\tau + A)^2}{w}. \quad (6.170)$$

being $A$ given by

$$dA = \Omega_q$$

The Kahler form of the new metric is simply

$$\Omega' = z\Omega_q + dz \wedge (d\tau + A), \quad (6.171)$$

and can also be expressed as

$$\Omega' = d(zA) + dz \wedge d\tau = dA', \quad A' = zA + zd\tau. \quad (6.172)$$

The coordinate $z$ plays a role of a momentum map of the isometry $\partial_\tau$.

### 6.2 Complete metrics

Let us consider a $2n$ dimensional Kahler-Einstein metric with sectional curvature normalized to one. This condition together with $B = 4\kappa$ fix the value $B = n + 1$. The metric (6.170) takes in this case the following form

$$g_6 = \frac{dr^2}{V} + \frac{r^2}{4} V (dt + A)^2 + \frac{r^2}{4} g_{fs}, \quad (6.173)$$

being $V$ given by

$$V = 1 - \left(\frac{a}{r}\right)^{2n+2} - \frac{\Lambda}{2(n+2)} r^2. \quad (6.174)$$
There is an apparent singularity at the zeroes $r_0$ of $V$. Nevertheless such singularities can be removed for certain values of the parameters of the metric \[66\]-\[36\]. If $\Lambda > 0$ then the metric will be complete if and only if $a = 0$ and the base space is $CP(n)$ with its canonical metric. In this case the total space will be $CP(n + 1)$ with the Fubbini-Study metric \[36\]. If instead $\Lambda < 0$ there exist another complete metrics for certain values of the parameters \[66\]. This is seen as follows. Let us consider the fiber metric

$$g_f = \frac{dr^2}{V} + \frac{r^2}{4} V dt^2,$$

and let us introduce the radial coordinate $R^2 = r^2 V$. The fiber metric have apparent singularities at the zeroes of $V$ and the coordinate $R$ tends to zero near the singularities. By differentiating (6.174) it is obtained that

$$\frac{dV}{dr} = \frac{2}{r} U, \quad U = (n + 1) \left(\frac{a}{r}\right)^{2n+2} - \frac{\Lambda}{2(n + 2)} r^2,$$  \hspace{1cm} (6.175)

and in terms of these quantities the fiber can be reexpressed as

$$g_f = (1 + \frac{R^2 r^2}{U})^{-\frac{1}{2}} dR^2 + \frac{R^2}{4} dt^2. \hspace{1cm} (6.176)$$

In a singularity point $r_0$ we have that $V(r_0) = 0$. Let us also suppose that $U(r_0) = p \in Z$. In this specific case the fiber metric (6.176) near the singularity takes the form

$$g_f \simeq \frac{1}{p^2} (dR^2 + R^2 d\tau^2),$$

being $2p \tau = t$. This means that the fiber metric extends smoothly across the singularity $R = 0$. The question now is to find values of the parameters $\Lambda$ and $a$ such that the conditions $U(r_0) = p \in Z$ and $V(r_0) = 0$ are realized. By using the expressions (6.175) for $U$ and $V$ it is found that these conditions reduce to an algebraic equation for $\Lambda$ and $a$ with solution

$$\Lambda = \frac{2(n + 1 - p)}{r_0^2}, \quad a^{2n+2} = (r_0)^{2n+2} \frac{p + 1}{n + 2}, \hspace{1cm} (6.177)$$

which gives a further relation

$$(a^2 \Lambda)^{n+1} = (2n + 2 - 2p)^{n+1} \frac{p + 1}{n + 2}. \hspace{1cm} (6.178)$$

Thus, the metric extends smoothly across the singularity only if the parameters $a$ and $\Lambda$ are related by (6.178). We see from (6.177) that if $\Lambda < 0$ then $p \geq n + 2$. Also

$$\frac{dV}{dr} = \frac{2n + 2}{r^{2n+3}} a^{2n+2} - \frac{\Lambda}{n + 2} r > 0$$

for $r > 0$. This means that the metric is non singular for $r > r_0$. In particular if the Fubbini-Study metric is used as the base space, then the desingularization procedure
presented above corresponds to the desingularization $O(-p) \rightarrow C^{n+1}/Z_p$, being $O(-(n + 1))$ the canonical bundle of $P^n$ \cite{66}.

Also, the case $\Lambda < 0$ corresponds to the parameters $p \geq 0$ and $s \leq 0$ in \eqref{6.169}. The fiber metric $g_f$ is two dimensional and by Gauss theorem, it is conformally flat. This means that there exist a coordinate system $(\rho, \tau)$ such that

$$p^2 g_f = p^2 w dz^2 + \frac{4d\tau^2}{w} = \Omega^2(\rho) (d\rho^2 + \rho^2 d\tau^2), \quad (6.179)$$

being $\Omega^2$ a conformal factor. From this equality we get the relation

$$\frac{d\rho}{dz} = p \frac{w^{1/2}}{\Omega}, \quad \frac{4}{w} = \rho^2 \Omega^2$$

By differentiating the second one we get that

$$4 \frac{dw^{-1}}{dz} = 2\rho^2 \Omega \frac{d\Omega}{dz} + 2\rho \Omega^2 \frac{d\rho}{dz} = 2\Omega \rho^2 \frac{d\Omega}{dz} + 2\rho \Omega^2 \frac{w^{1/2}}{\Omega}.$$ 

By introducing the first relation one obtains that

$$4 \frac{dw^{-1}}{dz} = \frac{2}{w \Omega} \frac{d\Omega}{dz} + p \quad \iff \quad \frac{d \log(w \Omega^2)}{dz} = -pw$$

From the last equation we obtain that

$$\Omega^2 w = C \exp\{-p \int_0^z w dz\}$$

and this, together with the second \eqref{6.179} yields

$$\rho^2 = \frac{4}{w \Omega^2} = 4C^{-1} \exp\{p \int_0^z w dz\}.$$ 

From \eqref{6.169} it is obtained that

$$w^{-1} = pz^2 + q + \frac{s}{z^n}$$

and using that for $\Lambda \leq 0$ we have $p \geq 0$ and $s \leq 0$ it follows that for any positive constant $C_0$ there exists a value $z_0 > \sqrt{r_0}$ such that any $z > z_0$ we have that

$$w^{-1} \geq \frac{p}{n+2} z^2 + C_0^2,$$

from where it follows that

$$\int_{\sqrt{r_0}}^z w \leq \int_{\sqrt{r_0}}^{z_0} w + \frac{A_0}{C_0^2} (\arctan \frac{z}{A_0} - \arctan \frac{z_0}{A_0}), \quad A_0 = C_0 \sqrt{\frac{n+2}{A}}.$$ 

From the last inequality it is seen that for $z \to \infty$ the function $\rho$ approaches to a constant. In other words $\rho$ is a bounded function and hence the fiber metrics are defined on an open disk. This result is independent on the choice of the base space and is one of the key ingredient to prove that the open disk bundle of $O(-p) \rightarrow P^n$ admit a complete Kahler-Einstein metric with negative scalar curvature with $SU(n + 1) \times U(1)$ invariant \cite{66}. 

54
6.3 The Calabi-Yau limit

It is of interest to consider the Ricci-flat limit of the metrics defined by (6.174) and (6.173). The resulting metric will be Ricci-flat Kahler, thus Calabi-Yau, and its holonomy will be included in $SU(3)$. But we have already mentioned that these metrics are complete only if the parameters are constrained by (6.177). In the Ricci-flat limit this condition is not satisfied and thus we do not have criteria to know if the result will be a complete metric, except in the case $a = 0$ for which $V = 1$. We see that it deserve the attention to study the Ricci flat limit $A = -2\Lambda = 0$ of equations (6.166) directly, instead of taking the limit to known solutions.

In references [68]-[69] there have been made certain advances in constructing complete Calabi-Yau metrics, which we describe here briefly. The Ricci flat limit of the system (6.166) is

$$
4 \frac{\partial^2 u}{\partial \xi^\lambda \partial \xi^\mu} + B \frac{\partial h_{\lambda \mu}}{\partial z} = 0
$$

$$
\frac{\partial u}{\partial z} = w,
$$

(6.180)

$$
4 \frac{\partial^2 h_{ab}}{\partial z^2} + \frac{\partial^2 w}{\partial \xi^a \partial \xi^b} = 0.
$$

From (6.164) it is obtained that $u = \log w^{-1} \det h$. From these equality together with the second equation (6.180) it is deduced that

$$
w^{-1} = \int_0^z \frac{\det h}{\det h}.
$$

(6.181)

In addition, by multiplying the first of (6.180) by $d\xi^\lambda \wedge \xi^\mu$ and summing over the repeated indices gives

$$
\frac{d}{dz} \Omega_h(z) = -i\overline{\partial} u.
$$

(6.182)

Combining formula (6.182) with the definition of $u$ gives

$$
\frac{d}{dz} \Omega_h(z) = \rho(h) - i\overline{\partial} \log w
$$

(6.183)

and from the last formula together with (6.181) we obtain

$$
\frac{d}{dz} \Omega_h(z) = -i\overline{\partial} \int_0^z \det h.
$$

(6.184)

If we were able to find a triplet $(h(z), \Omega_h(z), w)$ solving these equations then we will construct a Calabi-Yau metric in six dimensions with local form

$$
g = h + w dz^2 + w^{-1}(d\tau + A)^2,
$$

(6.185)
being $A$ a 1-form obtained from (6.161), which in our case reduces to

$$dA = \frac{i}{2} \partial_z h_{ab} \xi^a \wedge d\xi^b + i \frac{\partial w}{\partial \xi^c} dz \wedge d\xi^k - i \frac{\partial w}{\partial \xi^c} dz \wedge d\xi^k.$$  

Here $(\xi^k, \xi^k)$ are complex coordinates for $h(z)$.

A simple solution can be found starting with a four dimensional Kahler-Einstein metric $g_4$ with Kahler form $K$ defined over a manifold $X_4$, as in the previous subsection. Let us consider the two form

$$\Omega_h(z) = J + z \rho(J), \quad (6.186)$$

being $J$ the Kahler form for $g_4$. Because $g_4$ is Kahler-Einstein we have that $\rho(J) = \Lambda J$. This implies that

$$\Omega_h(z) = (1 + \Lambda z) J.$$  

We also have that

$$\Omega_h(z) \wedge \Omega_h(z) = P(z) J \wedge \bar{J}$$

being $P(z) = (1 + \Lambda z)^2$ and therefore $\rho(J) = \rho(\Omega_h)$. By introducing (6.186) in (6.183) and using $\rho(J) = \rho(\Omega_h)$ we see that $\Omega_h(z)$ is a solution of (6.183). The corresponding metric $h(z)$ is simply a $z$-dependent dilatation of $g_4$, namely

$$h(z) = (1 + \Lambda z) g_4, \quad (6.187)$$

and from (6.181) we see that

$$w^{-1} = \int_0^z (1 + \Lambda x)^2 dx = \frac{(1 + \Lambda z)^3 - 1}{3 \Lambda (1 + \Lambda z)^2}. \quad (6.188)$$

By defining $r^2 = 1 + \Lambda z$ the metric take the following asymptotically conical form

$$g_6 = \frac{r^2}{9} \left(1 - \frac{1}{r^6}\right)(d\tau + A)^2 + \frac{r^6}{(r^6 - 1)} dr^2 + \frac{\Lambda}{3} r^2 g_4 \quad (6.189)$$

with $dA = \bar{J}$. This metric possess holonomy in $SU(3)$ and depends on $\Lambda$ and the other parameters of the basis $g_4$. An important result given in [68] is that if $\Lambda > 0$ then the metric (6.189) is complete over the canonical bundle $K_X$ of $X_4$. In addition it is clear that (6.189) is asymptotically conical, that is, for large values of $r$ it tends to a cone of the form $dr^2 + r^2 g_5$ being $g_5$ the Einstein-Sassaki metric given by

$$g_5 = \frac{1}{9} (dt + A)^2 + \frac{\Lambda}{3} g_4.$$

Nevertheless this metric is Calabi-Yau for any value of $r$, not only asymptotically, and thus (6.189) provides a deformation of such cones without spoiling the Calabi-Yau condition.
In order to illustrate this construction, we can extend the Kahler-Einstein metrics obtained in [44]-[40] to an asymptotically conical Calabi-Yau metric. The result is

\[ g_6 = \frac{r^6}{(r^6 - 1)} dr^2 + \frac{r^2}{9} (1 - \frac{1}{r^6}) (d\tau - \cos \theta d\varphi + y(\beta + c \cos \theta d\varphi))^2 + 2r^2 (1 - cy) \frac{(d\theta^2 + \sin^2 \theta d\varphi^2)}{6} + \frac{2r^2 dy^2}{w(y)q(y)} + \frac{2w(y)q(y)}{36} (d\beta + c \cos \theta d\varphi)^2 \]  

(6.190)

where we have defined

\[ w(y) = \frac{2(a - y^2)}{1 - cy}, \quad q(y) = \frac{a - 3y^2 + 2cy^3}{a - y^2}. \]

If we select \( c = 0 \) and \( a = 3 \) the metric will be asymptotically a cone over \( T^{1,1} \). If we select instead \( c = a = 1 \) then the five dimensional metric will be \( S^5 \).

There exist another solutions \((h(z), \Omega_h(z), w)\) of the system \((6.181)-(6.183)\) that can be found starting with a Kahler manifold \( M \) with metric \( g_4 \) which is not Einstein, but possess constant eigenvalues of the Ricci curvature. Let us consider first the case in which the metric possess two different eigenvalues \( \lambda_1 \) and \( \lambda_2 \) with multiplicity two. This case has been studied recently in [72]. We will show that \((6.186)\) still represents a solution although in this case \( \rho(J) \neq \Lambda J \). For any Kahler manifold \( M \) with constant eigenvalues of the Ricci curvature the Ricci form \( \rho \) and the Kahler form \( J \) will be generically

\[ J = J_1 + J_2, \quad \rho = \lambda_1 J_1 + \lambda_2 J_2. \]

In addition we always have that

\[ \rho \wedge J = s \omega \]

being \( \omega \) the volume form of \( M \) and \( s \) the scalar curvature, which in our case is \( s = 2\lambda_1 + 2\lambda_2 \). We also have that

\[ J_1 \wedge J_1 = J_2 \wedge J_2 = 0, \quad J_1 \wedge J_2 = 2\omega. \]

By using this relations it is direct to check that

\[ \Omega_h(z) \wedge \Omega_h(z) = P(z) J \wedge J, \]

being \( P(z) = (1 + \lambda_1 z)(1 + \lambda_2 z) \). Therefore we have again that \( \rho(J) = \rho(\Omega_h) \) and thus \((6.186)\) is a solution of \((6.183)\). The function \( w \) is given by \((6.181)\), the result is

\[ w^{-1} = \int_0^z P(x) dx = \frac{1 + \lambda_1 z}{2\lambda_1} + \frac{1 + \lambda_2 z}{2\lambda_2} - \frac{1}{(1 + \lambda_1 z)(1 + \lambda_2 z)} \left( \frac{1}{2\lambda_1} + \frac{1}{2\lambda_2} \right). \]  

(6.191)

The metric \( h(z) \) is the metric for which \( \Omega_h(z) \) is the Kahler form. The procedure in order to find it is as follows. One need to find a basis of soldering forms \( \tilde{e}^1(z) \) such that

\[ \Omega_h(z) = \tilde{e}^1(z) \wedge \tilde{e}^2(z) + \tilde{e}^3(z) \wedge \tilde{e}^4(z) \]
The metric $h(z)$ will be given by $h(z) = \bar{e}^i(z) \otimes \bar{e}^i(z)$.

An special case of Kahler spaces with two degenerate eigenvalues is given as follows. The two forms $\overline{J}_i$ are characterized by

$$\overline{J}_1 = J(\pi_1 X, \pi_1 Y), \quad \overline{J}_2 = J - \overline{J}_1,$$

being $\pi_1$ the projection from $TM$ to $E_1$, being $E_1$ the corresponding $J$ invariant subspace associated to the eigenvalue $\lambda_1$. The closure of $\overline{J}$ and $\rho$ implies that $\overline{J}_i$ are also closed. The almost complex structure $\bar{J}$ defined by $\bar{J}|_{E_1} = J|_{E_1}$ and $\bar{J}|_{E_2} = -J|_{E_2}$ commutes with $J$ and the corresponding two form

$$\bar{J} = \overline{J}_1 - \overline{J}_2,$$

is symplectic and possess opposite orientation with respect to the one defined by $\overline{J}$. This means that

$$\bar{J} \wedge \bar{J} = -\overline{J} \wedge \overline{J} = 2\omega.$$

It has been shown that the symplectic two form $\bar{J}$ is integrable if and only if the base space $M$ is a direct product of two Kahler-Einstein spaces [72]. In this case $(g_4, \bar{J})$ will be a Kahler structure with orientation opposite to $(g_4, J)$, and $\overline{J}_1$ and $\overline{J}_2$ will be the Kahler forms for such metrics. As an example we can consider the product of the two dimensional Fubbini-Study metric $g_{fs}$ with the Bergmann one $g_b$. We normalize the curvature as $\lambda = \pm 1$. With the corresponding Kahler forms $\overline{J}_{fs}$ and $\overline{J}_{b}$ we consider the two form

$$\Omega_{h(z)} = (1 + z)\overline{J}_1 + (1 - z)\overline{J}_2,$$

which by construction is a solution of (6.181). The corresponding metric $h(z)$ is given by

$$h(z) = (1 + z)g_{fs} + (1 - z)g_b.$$  

From (6.191) we see that $w = 1/z$ in this case, and the Calabi-Yau metric reads

$$g_6 = (1 + z)g_{fs} + (1 - z)g_b + \frac{1}{z}dz^2 + z(dt + A)^2,$$

being $A$ given by $dA = \overline{J}_1 - \overline{J}_2$. Observe that in general $dA = \rho(\overline{J})$.

Another class of Kahler manifolds with constant Ricci eigenvalues are homogeneous Kahler manifolds, for which the holomorphic isometries acts transitively. There also exist non homogeneous Kahler metrics in the literature with constant eigenvalues of the Ricci curvature. An example is the family

$$g = e^u x(dx^2 + dy^2) + xdz^2 + \frac{1}{x}(dt + ydz)^2,$$

which possess this property if $u$ is a function satisfies

$$u_{xx} + u_{yy} = sxe^u.$$ 

(6.194)
The constant $s$ is the scalar curvature of the metric. The family (6.193) is Kahler and in general non homogeneous, except for certain subcases. For instance by selecting $u = 3 \log x$ it is obtained the Kahler metric

$$g = \frac{dx^2}{x^2} + \frac{dy^2}{x^2} + x dz^2 + \frac{(dt + y dz)^2}{x^2},$$

(6.195)

with Kahler form

$$\mathcal{J} = -dz \wedge dy + dy \wedge d(\frac{1}{x}).$$

This metric possess two different eigenvalues of the curvature tensor. If we make the variable change

$$u_1 = \frac{x^2 + y^2 - 1}{2x}, \quad v_1 = -\frac{y}{x}, \quad u_2 = t, \quad v_2 = z$$

(6.196)

then the metric takes the form

$$g = (-u_1 + \sqrt{u_1^2 + v_1^2 + 1}) du_1^2 + (u_1 + \sqrt{u_1^2 + v_1^2 + 1}) dv_1^2 - 2v_1 dv_1 dv_2$$

(6.197)

$$\frac{1}{(u_1^2 + v_1^2 + 1)} [(1 + v_1^2) du_1^2 + (1 + u_1^2) dv_1^2 - 2u_1v_1 dv_1 dv_2].$$

It has been shown that this metric is homogeneous and non symmetric in $[73]$ and the Ricci eigenvalues are $(0, 0, -\frac{3}{8}, -\frac{3}{8})$. But the metrics (6.193) are non homogeneous in general.

It has been shown that in general, the resulting Calabi-Yau metric will be complete if the Ricci eigenvalues are all positive $[68]$. This is not the case for for many of the examples that we have constructed so we can not decide whether or not the resulting Calabi-Yau metrics are complete. It is then of interest to classify which solutions of the equation (6.193) give rise to metrics with positive eigenvalues. Nevertheless this could be a hard task, due to the non linear nature of (6.193).

7. Discussion

Along this paper we considered an infinite family of tri-Sasaki 7-metrics and its squashed version, which are of weak $G_2$ holonomy. We have found in particular, a large class of examples with $T^3$ isometry. We constructed several new supergravity backgrounds and their deformed by use of the Maldacena-Lunin prescription. This should correspond to a marginal deformation in the dual theory. We have found in certain manifold limit a rotating configuration reproducing the logarithmic behaviour of the difference between the spin and the energy. We have found the same behaviour for the deformed background, although this is not a direct product of $AdS_4$ with a seven dimensional space.

We want to emphasize that there is an underlying linear structure describing all the backgrounds presented along this work. This is given by the (3.69) and in fact, all the
spaces that we have presented here are completely determined in terms of solutions of this equation. It will be nice to make a more deep analysis of the dual conformal theories of these backgrounds. Notice that the complete examples that we have presented are defined in terms of certain twistors. This is in part, a consequence of the underlying linear structure. It will be interesting to understand how these twistors are realized in the dual conformal field theory. Perhaps the methods presented in [61] could be useful for this purpose. Another interesting task is to figure out the pp-wave limit of these backgrounds and to study rotating configurations in the orbifold case. We hope to come out answering these questions in a near future.

A Quaternionic Kahler spaces in dimension higher than four

The generators $J^i$ of the Lie algebra $sp(1)$ of $Sp(1) \simeq SU(2)$ have the multiplication rule

$$J^i \cdot J^j = -\delta^{ij} I + \epsilon_{ijk} J^k;$$

which implies the $so(3) \simeq su(2)$ commutation rule

$$[J^i, J^j] = \epsilon_{ijk} J^k.$$  \hfill (1.199)

We see that $J^i J^i = -I$ and therefore $J^i$ will be called almost complex structures. An useful $4n \times 4n$ representation is

$$J^1 = \begin{pmatrix} 0 & -I_{n \times n} & 0 & 0 \\ I_{n \times n} & 0 & 0 & 0 \\ 0 & 0 & 0 & -I_{n \times n} \\ 0 & 0 & I_{n \times n} & 0 \end{pmatrix}, \quad J^2 = \begin{pmatrix} 0 & 0 & -I_{n \times n} & 0 \\ 0 & 0 & 0 & I_{n \times n} \\ I_{n \times n} & 0 & 0 & 0 \\ 0 & -I_{n \times n} & 0 & 0 \end{pmatrix},$$

$$J^3 = J^1 J^2 = \begin{pmatrix} 0 & 0 & 0 & -I_{n \times n} \\ 0 & 0 & -I_{n \times n} & 0 \\ 0 & I_{n \times n} & 0 & 0 \\ I_{n \times n} & 0 & 0 & 0 \end{pmatrix}.$$  \hfill (1.200)

The group $SO(4n)$ is a Lie group and this means in particular that for any $SO(4n)$ tensor $A_b^a$ the commutator $[A, J^i]$ will take also values in $SO(4n)$. We will say that $A$ belong to the subgroup $Sp(n)$ of $SO(4n)$ if and only if

$$[A, J^i] = 0.$$  \hfill (1.201)

Condition (1.201) together with (1.199) implies that a tensor $B^a_b$ belongs to the subgroup $Sp(n) \times Sp(1)$ if and only if

$$[B, J^i] = \epsilon_{ijk} J^j B^k_b.$$
being $B_k^k$ the components of $B$ in the basis $J^k$. Both conditions are independent of the representation.

We will write a metric over a 4n dimensional manifold $M$ as $g = \delta_{ab} e^a \otimes e^b$, being $e^a$ the 4n-bein basis for which $g$ is diagonal. Let us define the triplet of $(1, 1)$ tensors

$$J^i = (J^i)^a_b e_a \otimes e^b,$$  \hspace{1cm} (1.202)

defined by the matrices (1.200). If the holonomy is in $Sp(n) \times Sp(1)$, then from the beginning $\omega^a_b$ will take values on its lie algebra $sp(n) \oplus sp(1)$. As we saw above, this implies that

$$[\omega, J^i] = \epsilon_{ijk} J^j A^k.$$  \hspace{1cm} (1.203)

As usual, the connection $\omega^a_b$ is defined through

$$\nabla_X e^a = -\omega^a_b (X) e^b,$$

together with the Levi-Civita conditions $\nabla g = 0$ and $T(X, Y) = 0$. Using the chain rule $\nabla (A \otimes B) = (\nabla A) \otimes B + A \otimes (\nabla B)$ for tensorial products show us that in the einbein basis

$$[\omega, J^i] = \nabla_X J^i.$$  \hspace{1cm} (1.204)

Comparing (1.203) and (1.204) we see that quaternionic Kahler manifold are defined by the relation

$$\nabla_X J^i = \epsilon_{ijk} J^j A^k,$$

which is independent on the election of the frame $e^a$. This proves that (2.12) describe quaternion Kahler metrics [28] in dimension higher than four.

The basis $e^a$ for a metric $g$ is defined up to an $SO(4n)$ rotation. Under this $SO(4n)$ transformation the tensors (1.202) are also transformed, but it can be shown that the multiplication (1.198) is unaffected. In other words, given the tensors $J^i$ one can construct a new set of complex structures

$$J^a = C^a_j J^j,$$

$$J^a \cdot J^j = -\delta_i^j I + \epsilon_{ijk} J^k \hspace{1cm} \iff \hspace{1cm} C^a_k C^k_j = \delta^a_j.$$  \hspace{1cm} (1.205)

This can be paraphrased by saying that a quaternionic Kahler manifold has a bundle $V$ of complex structures parameterized by the sphere $S^2$. Using the textbook properties of $\nabla$ it can be seen that (2.12) is unaltered under such rotations.

Let us define three new tensors $(\tilde{J}^i)_{ab}$ by $(\tilde{J}^i)_{ab} = (J^i)^c_d \delta_{cb}$. From (1.200) it follows that

$$(J^i)_{ab} = - (J^i)^b_a \hspace{1cm} \iff \hspace{1cm} (\tilde{J}^i)_{ab} = - (\tilde{J}^i)_{ba}$$

This show that $(\tilde{J}^i)_{ab}$ are the components of the two-forms $\tilde{J}^i$ defined by

$$\tilde{J}^i = (\tilde{J}^i)_{ab} e^a \wedge e^b.$$  \hspace{1cm} (1.206)

The forms (1.200) are known as the hyperKahler forms. From (2.12) it is obtained that

$$\nabla_X J^i = \epsilon_{ijk} J^j A^k \hspace{1cm} \implies \hspace{1cm} d\tilde{J}^i = \epsilon_{ijk} A^j \wedge \tilde{J}^k,$$
being \( d \) the usual exterior derivative. The last implication proves relation (2.13).

If we change the frame \( e^a \) to a new one \( x^\mu \) then the definition \((\mathcal{J})_{ab} = (J^i)^a_\delta \delta_{eb}\) should be modified by the covariant one \((\mathcal{J})_{\alpha\beta} = (J^i)^\gamma_\alpha g_{\gamma\beta}\). Here the greek index indicates the components in the new basis and \( g_{\gamma\beta} \) are the corresponding components of the metric. Therefore

\[
(\mathcal{J})_{ab} = - (\mathcal{J})_{ba} \iff (J^i)^\gamma_\alpha g_{\gamma\beta} = (J^i)^\gamma_\beta g_{\gamma\alpha}
\]

The last relation is equivalent to

\[
g(J^i X, Y) = g(X, J^i Y) \iff g(X, Y) = g(J^i X, J^i Y)
\]

for arbitrary vector fields \( X \) and \( Y \) in \( TM \). Then the metric \( g \) will be always quaternion hermitian with respect to the complex structures. Relation (2.11) is also invariant under the automorphism of the complex structures.

In general, if in a given manifold there exist three complex structures satisfying (1.198), and we take intersecting coordinate neighborhoods \( U \) and \( U' \), then we have two associated basis \( J^i \) and \( J'^i \). Both basis should be related by an \( SO(3) \) transformation in order to satisfy (1.198). This means that any quaternion Kahler space is orientable [28]. Consider now the fundamental 4-form

\[
\Theta = \mathcal{J}^1 \wedge \mathcal{J}^1 + \mathcal{J}^2 \wedge \mathcal{J}^2 + \mathcal{J}^3 \wedge \mathcal{J}^3,
\]

and the globally defined \((2,2)\) tensor

\[
\Xi = J^1 \otimes J^1 + J^2 \otimes J^2 + J^3 \otimes J^3.
\]

By means of the formula (1.205) it follows that both tensors (1.207) and (1.208) are globally defined on the manifold \( M \). For a quaternionic Kahler manifold it is obtained directly from (2.12) and (2.13) that [28]

\[
\nabla \Theta = 0, \quad \nabla \Xi = 0.
\]

In \( D = 8 \) for a quaternion Kahler manifold \( d\Theta = 0 \) and if the manifold is of dimension at least 12 then \( d\Theta \) determines completely \( \nabla \Theta \). In particular \( d\Theta = 0 \) implies \( \nabla \Theta = 0 \) [79].

One of the most important consequences of (2.12) is that quaternionic Kahler spaces are always Einstein with cosmological constant [28]. The proof is briefly as follows. From the definition of the curvature tensor \( R(X, Y) = [\nabla X, \nabla Y] - \nabla_{\{X,Y\}} \) together with (2.12) it follows in the einbein basis that [28]

\[
R_{ijkm}(J^a)^m_j - R_{ijkm}(J^a)^m_j = \epsilon_{abc}(F^b)^i_{jk}(J^c)^l_k.
\]

where \( R_{ijkm} \) are the components of the curvature tensor and the two form \( F^a \) was defined as

\[
F^a = d\omega^a - \epsilon_{abc}\omega^b \wedge \omega^c.
\]

\(^3\)In the physical literature sometimes the three components \( \omega_\pm \) are referred as an \( SU(2) \) vector potential and \( F^a \) as the corresponding strength tensor.
We can rewrite (1.209) as a commutator

\[ [R(X, Y), J^a] = \epsilon_{abc} F^b J^c, \]

being \(X\) and \(Y\) arbitrary vector fields. Multiplying (1.209) by \((J^a)^i_l\) and contracting indices, and then multiplying by \((J^b)^k_l\) and using the identity \(4(J^a)^i_l(J^b)^k_l = 4n \delta^{ab}\),

gives the formula

\[ F^a_{ij} = \frac{1}{2n} R^l_{ijk} (J^a)^k_l. \] (1.210)

Inserting (1.210) into (1.209) yields

\[ R^l_{ijk} (J^a)^k_l = \frac{2n}{2 + n} R^m_{im} (J^a)^m_j, \]

which can also be expressed as

\[ R^i_- = \frac{2n}{2 + n} R \mathcal{T}^i, \] (1.211)

being \(R\) is the scalar curvature and \(R^i_-\) are the \(Sp(1)\) components of the curvature tensor. The second Bianchi identities together with (1.211) shows that \(R\) is constant and thus \(R_{ij} \sim g_{ij} \) [26]. Thus, in any dimension, quaternionic Kahler spaces are always Einstein with non zero cosmological constant \(\lambda\).

Because \(R\) is a constant we see from (1.211) that

\[ R^i_- = \Lambda \mathcal{T}, \] (1.212)

being \(\Lambda\) certain constant. We also have from (1.210) that

\[ F^i = \Lambda \mathcal{T}^i, \] (1.213)

being \(\Lambda^'\) another constant. In the limit \(\lambda \to 0\) the constants \(\Lambda\) and \(\Lambda^'\) goes simultaneously to zero.

If there exists a rotation of the local frame for which \(\omega_- = 0\) then the complex structures are locally covariantly constant, that is

\[ \nabla_X J^i = 0. \] (1.214)

In this case \(R^i_- = F^i = 0\) thus the space has self-dual curvature, which implies Ricci flatness. This spaces are called hyperKahler, and (1.214) shows that they are Kahler with respect of any of the complex structures. Condition (1.214) implies that the holonomy is in \(Sp(n)\) and that

\[ d\mathcal{T}^i = 0 \] (1.215)

together with the annulation of the Niejenhuis tensor given by

\[ N(X, Y) = [X, Y] + J[X, JY] + J[JX, Y] - [JX, JY]. \] (1.216)

A complex structure for which \(N(X, Y) = 0\) is called integrable.

\[ ^4\text{Which is clearly true in the representation (1.200)} \]

63

\[ ^63 \]
B Quaternion Kahler manifolds in dimension four

As we saw starting the previous section, in four dimensions the statement that the holonomy is \( \Gamma \subseteq Sp(n) \times Sp(1) \) is trivial due to the isomorphism \( SO(4) \simeq SU(2)_L \times SU(2)_R \simeq Sp(1) \times Sp(1) \). We will modify this definition and we will say that a four dimensional manifold \( M \) is quaternionic Kahler if \( (1.212) \) holds. This condition is not trivial, we will show below that quaternion Kahler spaces in \( d = 4 \) are Einstein (as in the higher dimensional case) and with self-dual Weyl tensor.

Let us consider a four dimensional metric \( g = \delta_{ab} e^a \otimes e^b \) and the connection \( \omega^a_b \) given by the first Cartan equation

\[
de e^a + \omega^a_b \wedge e^b = 0, \quad \omega^a_b = -\omega^a_{bi}.
\]

The notation \( SU(2)_\pm \) denote the \( SU(2)_L \) and \( SU(2)_R \) groups respectively. The \( SU(2)_\pm \) components of the spin connection are explicitly

\[
\omega^a_\pm = \omega^a_0 \pm \epsilon_{abc} \omega^b_c.
\]

(2.217)

The curvature tensor is given by the second Cartan equation

\[
R^a_b = d\omega^a_b + \omega^a_s \wedge \omega^s_b = R^a_{b,st} e^s \wedge e^t
\]

and the \( SU(2) \) parts are

\[
R^a_\pm = R^a_0 \pm \epsilon_{abc} R^b_c.
\]

(2.218)

The Ricci tensor is defined in the diagonal basis by \( R_{ij} = R^{a}_{i,aj} \) and the scalar curvature is \( R_{ii} = R \).

Instead of use the basis \( e^a \wedge e^b \) we can use the basis \( J^a_\pm = e^0 \wedge e^a \pm \epsilon_{abc} e^b \wedge e^c \). Then it follows that \( J^a_\pm \) are separately complex structure with definite self-duality properties, that is

\[
*J^a_\pm = \pm J^a_\pm.
\]

In this basis

\[
R^a_+ = A_{ab} J^b_+, \quad R^a_- = B_{ab} J^b_- + C_{ab} J^b_+
\]

(2.219)

where the matrices \( A \) and \( C \) are symmetric. The components of the Ricci tensor are

\[
R_{00} = Tr(A + B), \quad R_{0a} = \frac{\epsilon_{abc}}{2} (B_{bc} - B_{bc}), \quad R_{ab} = Tr(A - B) \delta_{ab} + B_{ab} + B_{ab}^t, \quad (2.220)
\]

and the scalar curvature is

\[
R = 4 Tr(A) = 4 Tr(C). \quad (2.221)
\]

It is clearly seen from (2.220) that the Einstein condition \( R_{ij} = \Lambda \delta_{ij} \) is equivalent to \( B = 0 \) and \( Tr(A) = Tr(C) = \Lambda \).

The components of the Weyl tensor in the diagonal basis are given by

\[
W^a_{bcd} = R^a_{bcd} - \frac{1}{2} (\delta_{ac} R_{bd} - \delta_{ad} R_{bc} + \delta_{bd} R_{ac} - \delta_{bc} R_{ad}) + \frac{R}{6} (\delta_{ac} \delta_{bd} - \delta_{ad} \delta_{bc}). \quad (2.222)
\]
The tensor $W$ is invariant under a conformal transformation $g \rightarrow \Omega^2 g$ and the associated two form is

$$W^a_b = W^a_{bcd} e^c \wedge e^d.$$ 

An explicit calculation shows that the $SU(2)_\pm$ of $W$ are

$$W^a_+ = W^a_0 + \epsilon_{abc} W^b_c = (A_{ab} - \frac{1}{3} Tr(A) \delta_{ab}) J^b_+, \\
W^a_- = W^a_0 - \epsilon_{abc} W^b_c = (C_{ab} - \frac{1}{3} Tr(C) \delta_{ab}) J^b_-.$$ 

From this expressions we see that to say that an Einstein space is self dual (i.e, $W^a_- = 0$) is equivalent to

$$C_{ab} = \frac{\Lambda}{3} \delta_{ab} \iff R^a_- = \frac{\Lambda}{3} J^a_-.$$ 

The second (2.223) is the same as (1.212) in four dimensions. Thus we conclude then that in $D = 4$ quaternionic Kahler is the same as self-dual Einstein.

**C The solution generating technique for IIB backgrounds**

The eleven supergravity backgrounds constructed in (5.133) possess three commuting Killing vectors. We can obtain $T^2$ IIA supergravity solutions by reduction along one isometry, say $\phi_3$. Also, by making a T-duality along another isometry, say $\phi_1$, we will obtain IIB supergravity backgrounds which are also toric. Now if we make the $SL(2,R)$ deformation of the original 11-dimensional backgrounds and we make the IIB reduction we will obtain a new background, the IIB deformed one. Comparison between the resulting expression will give a technique in order to deform a IIB background into another one. The result will be a one-parameter deformation. This is a particular case of a two parameter deformation that is known in the literature, which we will describe now.

Recall that any IIB background can be casted in the form

$$g_{IIB} = F \left[ \frac{1}{\sqrt{\Delta}} (D\alpha_1 - C(D\phi_2))^2 + \sqrt{\Delta} (D\alpha_2)^2 \right] + \frac{e^{2\phi/3}}{F^{1/3}} \tilde{g},$$

$$B = B_{12}(D\phi_1) \wedge (D\phi_2) + D\phi_1 \wedge B_1 + D\phi_2 \wedge B_2 - \frac{1}{2} A_m \wedge B_m + \frac{1}{2} \tilde{b},$$

$$C^{(2)} = C_{12}(D\phi_1) \wedge (D\phi_2) + D\phi_1 \wedge C_1 + D\phi_2 \wedge C_2 - \frac{1}{2} A_m \wedge C_m + \frac{1}{2} \tilde{c},$$

$$e^{2\phi} = e^{2\phi}, \quad C^{(0)} = \chi,$$ 

$$C^{(4)} = -\frac{1}{2} (\tilde{d} + B_{12} \tilde{c} - \epsilon_{mn} B_m \wedge C_n - B_{12} A_m \wedge C_m) \wedge D\phi_1 \wedge D\phi_2.$$
\[ + \frac{1}{6} [C + 3(\bar{b} + A_1 \wedge B_1 - A_2 \wedge B_2) \wedge C_{(1)}] \wedge D\phi_1 + d_4 + \hat{d}_3 \wedge D\phi_2, \]

where
\[ D\phi_2 = d\phi_2 + A_2, \quad D\phi_1 = d\phi_1 + A_1. \]

The effect of the \( SL(3, R) \) transformation over these backgrounds is the following. We have three objects which transform as vectors and tensors
\[
V^{(1)} = \begin{pmatrix} -B_2 \\ A_1 \\ C_2 \end{pmatrix}, \quad V^{(2)} = \begin{pmatrix} B_1 \\ A_2 \\ -C_1 \end{pmatrix} : \quad V^{(i)} \longrightarrow (\Lambda^T)^{-1}V^{(i)}; \quad (3.225)
\]

\[
W = \begin{pmatrix} \tilde{c} \\ \tilde{d} \\ \tilde{b} \end{pmatrix} \longrightarrow \Lambda W
\]

and one matrix
\[
M = gg^T, \quad g^T = \begin{pmatrix} e^{-\phi/3} F^{-1/3} & 0 & 0 \\ 0 & e^{-\phi/3} F^{2/3} & 0 \\ 0 & 0 & e^{2\phi/3} F^{-1/3} \end{pmatrix} \begin{pmatrix} 1 & B_{12} & 0 \\ 0 & 1 & 0 \\ \chi & -C_{12} + \chi B_{12} & 1 \end{pmatrix},
\]

with transformation law
\[
M \longrightarrow \Lambda M \Lambda^T. \quad (3.226)
\]

The scalars \( \Delta, C \) as well as the three form \( C_{\mu\nu\lambda} \) stay invariant under these \( SL(3, R) \) transformations. From these expression one can read the generic transformation of any of the fields.

We will restrict ourselves with a matrix of the form
\[
\Lambda = \begin{pmatrix} 1 & \gamma & 0 \\ 0 & 1 & 0 \\ 0 & \sigma & 1 \end{pmatrix}, \quad \Lambda^T = \begin{pmatrix} 1 & 0 & 0 \\ \gamma & 1 & \sigma \\ 0 & 0 & 1 \end{pmatrix}
\]
\[
\Lambda^{-1} = \begin{pmatrix} 1 & -\gamma & 0 \\ 0 & 1 & 0 \\ 0 & -\sigma & 1 \end{pmatrix}, \quad (\Lambda^T)^{-1} = \begin{pmatrix} 1 & 0 & 0 \\ -\gamma & 1 & -\sigma \\ 0 & 0 & 1 \end{pmatrix}
\]

Then the transformed fields are
\[
A'_1 = A_1, \quad A'_2 = A_2 - \sigma A_3, \quad A'_3 = A_3
\]
\[
\tilde{c}' = \gamma \tilde{c}, \quad \tilde{d}' = \tilde{d}, \quad \tilde{b}' = \sigma \tilde{d}
\]

In addition, the transformation law \( (3.226) \) implies that \( g^T \) should transform as \( g^T \rightarrow Rg^T\Lambda^T \) being \( R \) an \( SO(3) \) transformation. The Euler angles of this rotation should be
selected in order that the non diagonal matrix in the expression for $g^T$ conserve its form, that is, the components (2, 1), (1, 3) and (2, 3) should be zero. We have that

$$g^T \Lambda^T = \begin{pmatrix}
e^{-\phi/3} F^{-1/3} & 0 & 0 \\ 0 & e^{-\phi/3} F^{2/3} & 0 \\ 0 & 0 & e^{2\phi/3} F^{-1/3} \end{pmatrix}$$

$$\times \begin{pmatrix}1 + \gamma B_{12} & B_{12} & \sigma B_{12} \\ \frac{\gamma}{\chi + \gamma(\chi B_{12} - C_{12})} & 1 & \sigma \\ \chi B_{12} - C_{12} & 1 + \sigma(\chi B_{12} - C_{12}) & 0 \end{pmatrix}$$

which is not of the desired form. We have to multiply this expression for a rotation matrix $R(\alpha_1, \alpha_2, \alpha_3)$ and the condition that the components (2, 1), (1, 3) and (2, 3) vanish give the following system of equations

$$\cot \alpha_2 B_{12} = -\cos \alpha_3$$

$$\sin \alpha_2 + \cos \alpha_3 \cos \alpha_2 B_{12} = -(1 + \sigma G) \sin \alpha_3$$

$$(\sin \alpha_1 \cos \alpha_2 + \cos \alpha_3 \sin \alpha_2 \cos \alpha_1)(1 + \gamma B_{12}) + (\sin \alpha_1 \sin \alpha_2 - \cos \alpha_3 \cos \alpha_2 \cos \alpha_1)\gamma$$

$$-(\chi + \gamma G) \cos \alpha_1 \sin \alpha_3 = 0$$

The first two equations involve only $\alpha_2$ and $\alpha_3$. The angle $\alpha_1$ is then defined by the third equation, which turns out to be

$$\tan \alpha_1 = -\frac{\cos \alpha_3 \cos \alpha_2 \gamma - \cos \alpha_3 \sin \alpha_2 (1 + \gamma B_{12}) - (\chi + \gamma G) \sin \alpha_3}{(1 + \gamma B_{12}) \cos \alpha_2 + \gamma \sin \alpha_2}$$

The transformation of $F$ and $\phi$ is then obtained by requiring that for the non diagonal matrix in $g^T$ the diagonal elements are $g_{ii}^T = 1$. The transformed components were worked out for instance in [21], the result is

$$g_{11}^T = \frac{e^{-\phi/3}}{\mu} \kappa, \quad g_{12}^T = \frac{e^{5/3 \phi}}{\mu \kappa} (B_{12} + \gamma B_{12}^2 - B_{12} C_{12} \sigma + F^2 (\gamma - \chi \sigma)), \quad g_{22}^T = \frac{(e^{2\phi} F^2)^{1/3}}{\kappa},$$

$$g_{32}^T = \frac{e^{-\phi/3}}{\mu} (B_{12} \chi e^{2\phi} + C_{12}^2 \sigma e^{2\phi} + B_{12}^2 \sigma (1 + \chi^2 e^{2\phi}) + F^2 \sigma - C_{12} e^{2\phi} (1 + 2 B_{12} \chi \sigma))$$

$$g_{31}^T = \frac{e^{-\phi/3}}{\mu} (\sigma B_{12} + \gamma B_{12}^2 - B_{12} C_{12} \sigma + F^2 (\gamma - \chi \sigma))$$

$$B_{12}^2 \gamma + F^2 \gamma) - \chi e^{2\phi} (-1 + C_{12} \sigma + B_{12} \gamma (2 C_{12} \sigma - 1))$$

$$g_{33}^T = \frac{(e^{2\phi} F^2)^{1/3}}{\mu} \sqrt{(B_{12}^2 + F^2) \sigma^2 + e^{2\phi} (1 - C_{12} \sigma + B_{12} \chi \sigma)^2},$$

$$\mu = F^{1/3} \sqrt{(B_{12}^2 + F^2) \sigma^2 + e^{2\phi} (1 - C_{12} \sigma + B_{12} \chi \sigma)^2}$$

$$\kappa^2 = F^2 \sigma^2 + e^{2\phi} (B_{12} \gamma)^2 - 2 B_{12} \gamma (C_{12} \sigma - 1) + (C_{12} \sigma - 1)^2 + F^2 (\gamma - \sigma \chi)^2)$$

67
The transformed fields are then

\[ B'_{12} = \frac{g^T_{12}}{g^T_{11}}, \quad e^{\phi'} = \frac{g^T_{33}}{g^T_{11}}, \quad \chi' = \left( \frac{g^T_{22}g^T_{11}}{g^T_{33}} \right)^{1/3} \]

\[ C'_{12} = \chi' B'_{12} - g^T_{32}g^T_{22}g^T_{11}, \]  

(3.228)

and are completely determined in terms of the fields of the original IIB supergravity solution. The procedure is explicitly defined.

## D IIB deformed superbackgrounds for the spherical case

Let us consider our now the IIA reduction of our \( T^3 \) supergravity backgrounds of section 5. In order to perform the reduction to we need to make the decomposition

\[ M_{ab} D\phi_a D\phi_b = e^{-2\phi_D/3} \hbar_{mn} D\phi_m D\phi_n + e^{4\phi_D/3} (D\phi_3 + N_m D\phi_m)^2 \]  

(4.229)

with \( m, n = 1, 2 \). The metric \( \hbar \) should not be confused with the \( h \) appearing in \( \text{(5.135)} \)!

We find that

\[ \phi_D = \frac{3}{4} \log(M_{33}), \quad N_m = \frac{M_{3m}}{M_{33}}, \quad \hbar_{mn} = \frac{M_{mn}M_{33} - M_{3m}M_{3n}}{\sqrt{M_{33}}} \]

and is straightforward to find the IIA reduced background. By making a T-duality [101] to the resulting IIA background we obtain the IIB solution

\[ g_{IIB} = \frac{1}{h_{11}} \left[ \frac{1}{\sqrt{\Delta}} (D\phi_1 - C D\phi_2)^2 + \sqrt{\Delta} (D\phi_2)^2 \right] + e^{2\phi_D/3} g, \]

\[ B = \frac{h_{12}}{h_{11}} D\phi_1 \wedge D\phi_2 - D\phi_2 \wedge C_{(32)} + D\phi_1 \wedge A_1 - \frac{1}{2} C_{(3)} + C_{(31)} \wedge A_1 \]

\[ C^{(2)} = - (N_2 - \frac{h_{12}}{h_{11}} N_1) D\phi_1 \wedge D\phi_2 - D\phi_2 \wedge C_{(12)} - D\phi_1 \wedge A_3 - \frac{1}{2} C_1 + C_{(31)} \wedge A_3 \]

\[ e^{2\Phi} = \frac{e^{2\phi}}{h_{11}}, \quad C^{(0)} = N_1 \]  

(4.230)

\[ C^{(4)} = - \frac{1}{2} D\phi_2 \wedge D\phi_1 \wedge [C_{(2)} + 2C_{32} \wedge A_3 - \frac{h_{12}}{h_{11}} C_1 + 2C_{(31)} \wedge A_3] \]

\[ + \frac{1}{6} (C + 3C_{(3)} \wedge A_3) \wedge D\phi_1 + d_4 + \hat{d}_3 \wedge D\phi_1 \]

\[ D\phi_1 = d\phi_1 - C_{(31)}, \quad D\alpha_2 = d\phi_2 + A_2 \]

The forms \( d_4, \hat{d}_3 \) are determined by the self duality conditions for the five form field strength.
It will interesting how this procedure works for our example (5.151) associated to $S^4$. The relevant quantities that we need are

$$
\phi_D = \frac{3}{4} \log M_{\tau \tau} = -\frac{1}{4} \log \Delta
$$

$$
N_1 = - \sin \tilde{\rho} \sin \theta \cos \varphi, \quad N_2 = - \sin \theta (\sin \varphi \cos \tilde{\rho} \sin \tilde{\theta} + \cos \varphi \cos \tilde{\theta})
$$

$$
\tilde{h}_{11} = \frac{1 - (\sin \tilde{\rho} \sin \theta \cos \varphi)^2}{\Delta^{1/2}}, \quad \tilde{h}_{22} = \frac{1 - \sin^2 \theta (\cos \tilde{\rho} \cos \tilde{\theta} \sin \varphi + \cos \tilde{\theta} \cos \varphi)^2}{\Delta^{1/2}}
$$

$$
\tilde{b}_{12} = \frac{\sin \tilde{\rho} \cos \tilde{\theta} + \sin \tilde{\rho} \sin^2 \theta \cos \varphi \cos \tilde{\rho} \cos \tilde{\theta} \sin \varphi + \cos \tilde{\theta} \cos \varphi}{\Delta^{1/2}}
$$

(4.231)

We have that $\tilde{g} = \Delta^{1/6} (g_{\text{AdS}} + h)$ being $h$ given in (5.145) and $\Delta$ given in (5.140). The resulting IIB background is in this case

$$
g_{IIB} = \frac{1}{\tilde{h}_{11}} \left[ - \frac{1}{\sqrt{\Delta}} (D\phi_1)^2 + \sqrt{\Delta} (D\phi_2)^2 \right] + e^{2\phi_D/3} \tilde{g}_{\mu \nu} dx^\mu dx^\nu
$$

$$
B = \frac{\tilde{h}_{12}}{\tilde{h}_{11}} D\phi_1 \wedge D\phi_2 + D\phi_1 \wedge A_1 \quad e^{2\Phi} = \frac{e^{2\phi_D}}{\tilde{h}_{11}}, \quad C^0 = N_1
$$

$$
C^2 = -(N_2 - \frac{N_1}{\tilde{h}_{11}}) D\phi_1 \wedge D\phi_2 - D\phi_1 \wedge A_3
$$

$$
C^4 = \frac{1}{6} C^3 \wedge D\phi_1 + d^4 + \tilde{\theta}^3 \wedge D\phi_2
$$

$$
D\phi_1 = d\phi_1
$$

The one forms $A_i$ are defined in (5.143). The 3-form $\tilde{\theta}^3$ and the four form $d^4$ takes values in the eight-dimensional metric and are determined by imposing that the five form field strength $F_5 = dC_4$ is self-dual, that is $F_5 = *_{10} F_5$. In our case we have that

$$
C^3 = -\frac{k}{3} \sin u \sin^3 \rho \rho dt \wedge du \wedge dv
$$

$$
\frac{1}{6} d(C^3 \wedge D\phi_1) = -\frac{k}{6} \sin u \sin^2 \rho \rho \rho dt \wedge du \wedge dv \wedge d\phi_1
$$

and the self-duality condition is satisfied if $d^4$ is zero and

$$
C^4 = \frac{1}{6} (C^3 \wedge d\phi_1 + \sqrt{\Delta} \tilde{C}^3 \wedge D\phi_2)
$$

being $\tilde{C}^3$ such that $d\tilde{C}^3 = \sqrt{\Delta} *_{8} dC^3$. The hodge star operation $*_{8}$ concerns to the 8-dimensional metric $\tilde{g}$. By comparing these expressions with (3.224) we obtain that

$$
F = \tilde{h}_{11}, \quad B_{12} = \frac{\tilde{h}_{12}}{\tilde{h}_{11}}, \quad B_1 = B_2 = 0,
$$

$$
\bar{b} = \bar{c} = 0, \quad \bar{c}_{12} = \frac{\tilde{h}_{12}}{\tilde{h}_{11}} N_1 - N_2, \quad \bar{c}_1 = A_3, \quad \bar{c} = N_1
$$

and it follows that all these quantities are defined by formulas (4.231). From (3.227) and (3.228) we obtain directly the explicit deformed fields. The procedure is finished.
