Hydrolysis of Element (White) Phosphorus under the Action of Heterometallic Cubane-Type Cluster \{\text{Mo}_3\text{PdS}_4\}

Airt M. Kuchkaev 1,2, Nikita Y. Shmelev 1,3,4, Aidar M. Kuchkaev 1,2, Aleksandr V. Sukhov 1,2, Vasily M. Babaev 1, Khasan R. Khayarov 2, Artem L. Gushchin 3,* , Maxim N. Sokolov 3,4, Oleg G. Sinyashin 1 and Dmitry G. Yakhvarov 1,2,* 1

Abstract: Reaction of heterometallic cubane-type cluster complexes—\{\text{Mo}_3\text{PdS}_4\}\{\text{Pd(tu)}\}S_\text{3} \text{Cl}_3 \text{(dbbpy)}\text{Cl} and \{\text{Mo}_3\text{PdS}_4\}\{\text{Pd(acac)}\}\text{S}_\text{3} \text{Cl}_3 (\text{py})\text{Cl} \{\text{Pd(acac)}\}\text{S}_\text{3} \text{Cl}_3 (\text{py})\text{Cl}, where \text{dbbpy}—4,4′-di tert-butyl-2,2′-bipyridine, tu—thiourea, acac — acetylacetonate, py — pyridine, with white phosphorus (\text{P}_\text{4}) in the presence of water leads to the formation of phosphorous acid H_\text{3} \text{PO}_\text{4} as the major product. The crucial role of the \text{Pd} atom in the cluster core \{\text{Mo}_3\text{PdS}_4\} has been established in the hydrolytic activation of \text{P}_\text{4} molecule. The main intermediate of the process, the cluster complex \{\text{Mo}_3\text{PdO}_\text{3} \text{Cl}_\text{3} (\text{dbbpy})\text{Cl} \}^{+} with coordinated \text{P(OH)}\text{3} molecule and phosphine \text{PH}_\text{3}, have been detected by \text{31P} NMR spectroscopy in the reaction mixture.

Keywords: white phosphorus; heterometallic cubane-type clusters; molybdenum; palladium; phosphorous acid; phosphine

1. Introduction

Both organic and inorganic phosphorus-containing compounds have become widespread agents for various industrial applications. Traditional methods for the preparation of phosphorus compounds involve oxidation and chlorination of the element (white) phosphorus (\text{P}_\text{4}) and use the phosphorus chlorides as phosphorylating agents for the synthesis of various organophosphorus substrates. It should be noted that direct activation and transformation of \text{P}_\text{4} is a very harsh and risky process that involves toxic and hazardous reagents and waste, and which negatively impacts on the environment.

The oxidation of \text{P}_\text{4} in the presence of H_\text{2} \text{O} usually leads to the formation of phosphoric acid H_\text{3} \text{PO}_\text{4}, while phosphorous acid H_\text{3} \text{PO}_\text{3} is more interesting and important phosphorus precursor which can be used as a phosphorylating agent as it contains a functionally capable P-H bond. Moreover, the current methods for the preparation of H_\text{3} \text{PO}_\text{3} leave much to desire and require the use of toxic and hazardous phosphorus trichloride producing a huge amount of corrosive gaseous hydrogen chloride and dangerous phosphorus chloro-derivatives.

We have previously demonstrated that palladium complexes can be efficiently used for the preparation of phosphoric acid H_\text{3} \text{PO}_\text{4} directly from \text{P}_\text{4} by its mild hydrolysis in the coordination sphere of the metal [1,2]. However, the main limitation of these catalytic systems is the formation of catalytically inactive palladium phosphides and palladium black [3]. It is important to note, that ruthenium-mediated \text{P}_\text{4} hydrolysis was thoroughly studied in Florence in the scientific group of M. Peruzzini and P. Stoppioni. It
was shown that the hydrolysis of [CpRu(PPh₃)₂(η¹⁻P₄)] (Cp = cyclopentadienyl) complex leads to the formation of phosphine PH₃ and phosphorous acid H₃PO₃ [4,5]. Moreover, it has been established that the mechanism of this process may involve the formation of binuclear intermediate, when η²-P₄ unite is doubly coordinated to two [CpRu(PPh₃)₂] moieties, which is hydrolyzed with the formation of H₃PO₃ and previously unknown 1-hydroxytriposphane (PH(OH)PHPH₃) as the intermediate of the overall process [6]. Later this process was improved and the kinetic of P₄ hydrolysis was investigated using ruthenium complexes with water-soluble phosphine ligands [7]. There is also a notable example of stabilization of phosphorous acid H₃PO₃ in its tautomeric form P(OH)₃ on the Ru site [8]. Hence, further development of new methods of white phosphorus hydrolysis is of high interest.

Heterometallic cubane-type cluster complexes with [M₃Pd₄] (M = Mo, W) core that were first described by Hidai’s group in Japan [9,10] possess a number of attractive properties including unordinary reactivity and catalytic activity of the Pd site [11–22]. To cite the most recent example, [M₃Pd₄] clusters react with fullerene C₆₀ to form hybrid compounds containing a fullerene molecule coordinated to palladium in the cluster core [23]. The [M₃Pd₄] clusters catalyze alkylation of aromatics [24–26] and nucleophilic addition to triple bonds [10,27]. However, until now there have been no examples of P₄ molecule coordination and activation in the coordination sphere of the [M₃Pd₄] cluster core, despite reported ability of such clusters to stabilize the unstable species or less-favoured tautomers, such as As(OH)₃, P(OH)₅, PhP(OH)₂, Ph₂P(OH), HP(OH)₂ through coordination to the palladium site, which indicates high affinity of the latter for pnictogens. [28,29]. From these earlier studies, we have assumed that [M₃Pd₄] complexes could be involved in the process of P₄ activation and its transformation.

In this work we investigated the reactivity of heterometallic complexes [Mo₃(Pd(dbba))S₄Cl₃(dbbpy)]PF₆ (1), [Mo₃(Pd(tu))S₄Cl₃(dbbpy)]PF₆ (2) and [Mo₃(Pd(dbba))S₄(acac)₃(py)₃]PF₆ (3) towards element (white) phosphorus.

2. Results and Discussion

2.1. Synthesis and Characterization

The trinuclear cluster complexes with the [M₃S₄] (M = Mo, W) core are able to incorporate a range of transition metals in low oxidation state (from 0 to +2), affording heterometallic cubane-type derivatives [M₃M’S₄], where M’ = Cu, Ni, Pd, Pt, etc. [11,30–35].

The common approach for synthesis of the [M₃M’S₄] clusters involves the reaction of a low-valent metal precursor with a [M₃S₄] trinuclear complex in a desired coordination environment [12]. The same synthetic approach has been applied in current work, where [Pd₂(dbba)₃] × CHCl₃ was used as the palladium source. The synthetic routes to new cluster complexes 1 and 3 used in this work are depicted in Scheme 1. The cluster complex 2 has been obtained according to a previously published procedure [36].

The reaction of [Mo₃S₄Cl₃(dbbpy)]PF₆ with [Pd₂(dbba)₃] × CHCl₃ (2:1 molar ratio) in CH₂Cl₂ gives complex 1 in 54% yield. The complex 3 was prepared in a similar way in 47% yield from [Mo₃S₄(acac)₃(py)₃]PF₆ as starting compound. The formation and identity of 1 and 3 were confirmed by microanalysis and spectroscopic data.

The IR spectrum of 1 demonstrates the characteristic composite vibration bands, ν(C–C) and ν(C–N) at 1610 cm⁻¹; ν(C=C), δ(C–H), δ(C–N) and δ(Mo–N) in the 1480–1410 cm⁻¹ range; γ(C–H) and δ(C–H) in the 870–830 cm⁻¹ and 1380–1310 cm⁻¹ regions, and ring breathing bands from the coordinated dbbpy ligands in the 1028–906 and 766–423 cm⁻¹ regions. The spectral data are in agreement with those reported for complex 2 [36]. The intensive band (ν(C=O)) at 1625 cm⁻¹ testifies the coordination of dba ligand to the palladium atom, while bands at 839 and 555 cm⁻¹ belong to the hexafluorophosphate anion.
regions. The spectral data are in agreement with those reported for complex range; intensive band \((\text{CH}_2\text{Cl}_2 \text{ gives complex breathing bands from the coordinated } \text{dbbpy ligands in the } 1028–906 \text{ and } 766–423 \text{ cm}^{-1}\).

The IR spectrum of \([\text{Mo}_3\text{S}_4\text{(acac)}_3\text{(py)}]^+\), \(714.7\) \((\text{[Mo}_3\text{S}_4\text{(acac)}_3]^+)\) are detected in the spectrum of from m/z and characteristic isotope patterns.

The ESI-MS (+) of \([\text{Mo}_3\{\text{Pd(dba)}\text{S}_4\text{Cl}_3\text{dbbpy)}_3]^+\) (pseudomolecular peak), \(1436\) \((\text{[Mo}_3\text{PdS}_4\text{Cl}_3\text{dbbpy)}_3]^+)\), \(1327\) \((\text{[Mo}_5\text{S}_4\text{Cl}_3\text{dbbpy)}_3]^+)\) which result from \([\text{Mo}_3\text{(Pd(db)}\text{S}_4\text{Cl}_3\text{dbbpy)}_3]^+\) fragmentation under experimental conditions. The signals with m/z ratio of \(1057.8\) \((\text{[Mo}_5\text{PdS}_4\text{(acac)}_3\text{(py)}_3]^+)\), \(978.6\) \((\text{[Mo}_5\text{PdS}_4\text{(acac)}_3\text{(py)}_3]^+)\), \(899.6\) \((\text{[Mo}_5\text{PdS}_4\text{(acac)}_3\text{(py)}_3]^+)\), \(951.8\) \((\text{[Mo}_5\text{S}_4\text{(acac)}_3\text{(py)}_3]^+)\), \(870.8\) \((\text{[Mo}_5\text{S}_4\text{(acac)}_3\text{(py)}_3]^+)\), \(793.8\) \((\text{[Mo}_5\text{S}_4\text{(acac)}_3\text{(py)}_3]^+)\), \(714.7\) \((\text{[Mo}_5\text{S}_4\text{(acac)}_3\text{(py)}_3]^+)\) are detected in the spectrum of 3. The de-coordination of the pyridine ligands is expectable under ionization conditions and was also observed for the trinuclear \([\text{Mo}_3\text{S}_4]\) precursor \([38]\). All the peaks have been assigned both from m/z and characteristic isotope patterns.

2.2. Interaction with \(\text{P}_4\)

The reactivity of heterometallic cluster complexes \([\text{Mo}_3\text{(Pd(db)}\text{S}_4\text{Cl}_3\text{(dbbpy)}_3)]\text{PF}_6\) (1), \([\text{Mo}_3\text{(Pd(tu)}\text{S}_4\text{Cl}_3\text{(dbbpy)}_3]\text{Cl}\) (2) and \([\text{Mo}_3\text{(Pd(db)}\text{S}_4\text{(acac)}_3\text{(py)}_3]\text{PF}_6\) (3) towards \(\text{P}_4\) was investigated both in the absence and in the presence of water. According to \(31^P\) NMR spectra, addition of the equimolar amount of \(\text{P}_4\) to the solutions of these complexes in DMF, THF and CH\(_2\)Cl\(_2\) does not lead to transformation of \(\text{P}_4\) molecule, and no new signals from phosphorus-containing species were detected.

However, addition of water to the DMF solutions containing complexes 1 or 2 and \(\text{P}_4\) has led to the appearance of the signals associated with inorganic oxo-acids H\(_3\)PO\(_3\) (\(\delta\) 2.1 ppm) and \(\text{H}_2\)PO\(_4\) (\(\delta\) 0.9 ppm) with integral ratio of 3:4:1.0 (for 1) and 7:5:1.0 (for 2). Additionally, new signals around 110 ppm were detected. These signals correspond to the formation of \([\text{Mo}_3\text{(Pd(OH)}_3\text{S}_4\text{Cl}_3\text{(dbbpy)}_3]^+\) (Figure 1), in which the Pd atoms bears the tautomeric form of phosphorous acid H\(_3\)PO\(_3\) (P(OH)\(_3\)) formed by the hydrolysis.
of white phosphorus. These results nicely fit with the previously published data [28, 29], where the signals around 115 ppm in $^{31}$P NMR spectra were attributed to the complexes $[\text{Mo}_3\text{PdP(OH)}_3\text{S}_4\text{H}_2\text{O}]$$_9$$_{3+}$, obtained by the reaction of $[\text{Mo}_3\text{PdClS}_4\text{H}_2\text{O}]$$_9$$_{3+}$ with $\text{PCl}_3$ or $\text{H}_3\text{PO}_3$ in 4M HCl. The total conversion of white phosphorus (by $^{31}$P NMR spectroscopy) in these reactions was 96.7% for complex 1 and 68.0% for complex 2.

![Figure 1](image_url). Structure of $[\text{Mo}_3\{\text{PdP(OH)}_3\}\text{S}_4\text{Cl}_3\text{(dbbpy)}]^{+}$.

In order to boost the activity of clusters 1 and 2, we attempted modification of their ligand surrounding by the substitution of the chloride-ions from the first and the second coordination spheres with weakly coordinated ions, and in this way to increase the electrophilic properties of Pd. Indeed, addition of TINO$_3$ as a halide scavenger increased the reactivity of the cluster towards P$_4$. As a result, increased intensity of the signals related to $\text{H}_3\text{PO}_3$ and $\text{H}_3\text{PO}_4$, and the decreased intensity of the P$_4$ signal were observed in $^{31}$P NMR spectra. In the case of complex 1, full conversion of P$_4$ was accomplished with a 72.0% yield of $\text{H}_3\text{PO}_3$. Complex 2 gave 74.4% conversion of P$_4$ and 53.1% yield of $\text{H}_3\text{PO}_3$.

Addition of H$_2$O to the reaction mixture containing $[\text{Mo}_3\{\text{PdP(OH)}_3\}\text{S}_4\text{Cl}_3\text{(py)}]^{+}$ (3) in DMF and P$_4$ also allowed for the appearance of the signals associated with $\text{H}_3\text{PO}_3$ and $\text{H}_3\text{PO}_4$. The conversion of P$_4$ (34.4%) was, however, substantially lower than with 1 and 2 and no signal attributed to $[\text{Mo}_3\{\text{PdP(OH)}_3\}\text{S}_4\text{(acac)}\text{(py)}]^{+}$ was observed in $^{31}$P NMR spectrum. This can be explained by assuming $[\text{Mo}_3\{\text{PdP(OH)}_3\}\text{S}_4\text{Cl}_3\text{(py)}]^{+}$ being less stable than $[\text{Mo}_3\{\text{PdP(OH)}_3\}\text{S}_4\text{Cl}_3\text{(dbbpy)}]^{+}$, and quickly releases $\text{P(OH)}_3$, which tautomerizes into the final product—phosphorous acid. The observed yield of $\text{H}_3\text{PO}_3$ was only 20.1%.

The solvent influence on the reactivity of P$_4$ and its hydrolysis was also investigated, using the complex 1 as the benchmark. Addition of an excess of H$_2$O to the reaction mixture containing 1 and P$_4$ in CH$_2$Cl$_2$ allowed for detection of the signals associated with $\text{H}_3\text{PO}_3$ and $\text{H}_3\text{PO}_4$. The conversion of P$_4$ was 43.1% with only 8.6% yield of $\text{H}_3\text{PO}_3$.

In case of THF as the solvent, the addition of H$_2$O to the reaction mixture containing 1 and P$_4$ yielded the signal associated with $[\text{Mo}_3\{\text{PdP(OH)}_3\}\text{S}_4\text{Cl}_3\text{(dbbpy)}]^{+}$ with $\delta$ +113.8 ppm in $^{31}$P NMR spectrum. It is worth noting that there were no signals of any phosphorus-containing acids in $^{31}$P NMR spectra in this case. However, the activation of the complex with TINO$_3$ caused both the signal growth and the appearance of new signals related to $\text{H}_3\text{PO}_3$ ($\delta$ 3.3 ppm), $\text{H}_3\text{PO}_4$ ($\delta$ 1.1 ppm), and PH$_3$ ($\delta$ −244.4 ppm). The integrated intensity ratio $\text{H}_3\text{PO}_3$:$\text{H}_3\text{PO}_4$ was 8:3, and the observed conversion of P$_4$ was 85.5% with 24.4% yield of $\text{H}_3\text{PO}_3$.

The summary of the results obtained in the reaction of $[\text{Mo}_3\text{PdS}_4]$ complexes with P$_4$ is presented in Table 1.
Table 1. Interaction of \([\text{Mo}_3\text{PdS}_4]\) complexes 1–3 with \(\text{P}_4\).

| Complex. | Solvent | Complex + \(\text{P}_4\) + \(\text{H}_2\text{O}\) | Complex + \(\text{P}_4\) + \(\text{H}_2\text{O}\) + \(\text{TlNO}_3\) |
|----------|---------|--------------------------------|--------------------------------|
|          |         | Conversion of \(\text{P}_4\) (%) | Conversion of \(\text{P}_4\) (%) | Yield of \(\text{H}_3\text{PO}_3\) (%) | Yield of \(\text{H}_3\text{PO}_3\) (%) |
| 1        | DMF     | 96.7 | 61.5/20.5 | 100.0 | 72.0/27.9 |
|          | \(\text{CH}_2\text{Cl}_2\) | 33.6 | 6.1/1.2 | 43.1 | 8.6/4.3 |
|          | THF     | 14 | 0/0 | 85.5 | 24.4/10.4 |
| 2        | DMF     | 68.8 | 37.1/3.7 | 74.4 | 53.1/16.2 |
| 3        | DMF     | 34.4 | 20.1/11.6 | - | - |

It should be noted, that the presence of the \(\text{Pd}\) site in the cluster moiety to realise the hydrolysis of \(\text{P}_4\) molecule is mandatory, as this reaction does not proceed with \(\text{Pd}\)-free trinuclear cluster complexes \([\text{Mo}_3\text{S}_2\text{Cl}_3\text{(dbbpy)}_3]\)\(\text{Cl}\) and \([\text{Mo}_3\text{S}_2\text{Cl}_3\text{(dbbpy)}_3]\)\(\text{PF}_6\). This fact confirms that the transformation and followed hydrolysis of \(\text{P}_4\) requires the presence of \(\text{Pd}\) center. Moreover, the use of cluster core \([\text{Mo}_3\text{PdS}_4]\) for hydrolysis of white phosphorus tetrahedron and its transformation into phosphorous acid (\(\text{H}_3\text{PO}_3\)) allows to avoid the formation of the insoluble and inactive \(\text{Pd-black}\) that is very important for the further use of these \([\text{Mo}_3\text{PdS}_4]\) clusters as catalysts for the hydrolysis of white phosphorus.

3. Conclusions

Based on the experimental data, we can conclude that heterometallic cubane-type clusters \([\text{Mo}_3\text{Pd(dbca)}\text{S}_3\text{Cl}_3\text{(dbbpy)}_3]\)\(\text{PF}_6\) (1), \([\text{Mo}_3\text{Pd(tu)}\text{S}_3\text{Cl}_3\text{(dbbpy)}_3]\)\(\text{Cl}\) (2) and \([\text{Mo}_3\text{Pd(dbca)}\text{S}_3\text{(acac)}_3\text{(py)}_3]\)\(\text{PF}_6\) (3) efficiently promote the hydrolysis of \(\text{P}_4\) molecule leading to the formation of \(\text{H}_3\text{PO}_3\) as the major product. The complexes 1 and 2 bearing ddbbpy ligand demonstrate higher activity in comparison with complex 3 containing acac ligand. Moreover, removal chloride anions from the coordination sphere of the cluster core with \(\text{TINO}_3\) increases both the activity of the cluster complexes in \(\text{P}_4\) activation process and the yield of \(\text{H}_3\text{PO}_3\). The use of the cluster with embedded \(\text{Pd}\) atom allows to avoid the \(\text{Pd-black}\) formation which occurs when non-cluster \(\text{Pd}\) complexes are used for white phosphorus hydrolysis process. Thus, this work opens up prospects for studying the potential of heterometallic cubane-type clusters as catalysts for the selective conversion of white phosphorus to phosphorous acid. Further studies are in progress.

4. Experimental Section

CAUTION: White phosphorus and phosphine mentioned in this communication are hazardous compounds. White phosphorus needs to be stored under water in a well-ventilated dark place. White phosphorus is highly toxic and burns spontaneously when exposed to air. In an emergency, white phosphorus can be treated with aqueous copper(II) sulfate solution or sand. On contact with skin, white phosphorus gives highly painful, badly healing burns. In case of skin burns, washing with diluted aqueous solutions of \(\text{KMnO}_4\) or \(\text{CuSO}_4\) is advised. The continuous inhaling of white phosphorus vapors results in disease of the bone tissue, loss of teeth, and necrosis of parts of the jaw. An aqueous copper(II) sulfate solution (2%) can be used as an immediate antidote for poisoning. All reactions and handling of phosphine and white phosphorus must be carried out under an inert atmosphere in a well-ventilated hood.

All experiments related to the synthesis of the complexes, preparation of the solutions, solvents, and the manipulations with white phosphorus and all chemical reagents were performed under nitrogen atmosphere using standard Schlenk-line techniques.

Trinuclear precursors \([\text{Mo}_3\text{S}_2\text{Cl}_3\text{(dbbpy)}_3]\)\(X\) (\(X = \text{Cl}^-\), \(\text{PF}_6^-\); \(\text{dbbpy} = 4,4’\text{-di-tert-Bu-2,2’-bipyrindine}\)) [39] and \([\text{Mo}_3\text{S}_4\text{(acac)}_3\text{(py)}_3]\)\(\text{PF}_6\) (acac—acetylacetonate, py—pyridine) [40] used to synthesize complexes 1, 2 and 3 as well as complex \([\text{Mo}_3\text{Pd(tu)}\text{S}_3\text{Cl}_3\text{(dbbpy)}_3]\)\(\text{Cl}\) (2) (tu—thiourea) [36], were prepared according to the published procedures. Commercially
available reagents \([\text{Pd}_2(\text{dba})_3] \times \text{CHCl}_3\) (\text{dba}—dibenzylideneacetone) (Sigma-Aldrich, Steiheim, Germany), thallium(I) nitrate (99.5%, ACROS Organics, Geel, Belgium) were used as purchased. White phosphorus was stored under a protective nitrogen atmosphere in a flask filled with water in a dark place and was washed sequentially in ethanol, acetone, and diethyl ether prior to use. 0.05 M THF solution was prepared by dissolving P4 in a required amount of solvent. Organic solvents were distilled before used.

Elemental C, H, N analyses were performed with a EuroEA3000 Eurovector analyzer (Eurovector SpA, Milano, Italy). IR spectra of samples in KBr pellets were recorded in the 4000–400 cm\(^{-1}\) range with a Perkin-Elmer System 200 FTIR spectrometer (PerkinElmer, Waltham, Massachusetts, USA). \(^1\)H and \(^31\)P\(^{1}\)H NMR spectra were registered at room temperature on a Bruker Avance III 400 MHz spectrometer (Bruker, New York, New York, USA) at frequencies of 400.0 \((^1\)H) and 161.9 \((^{31}\)P) MHz. UV–vis spectra were recorded with a Specord M40 (Carl Zeiss, Jena, Germany), Helios \(\gamma\) spectrophotometer (ThermoFisher Scientific, Waltham, Massachusetts, USA) in the 200–900 nm range in the CH\(_3\)CN solution. A mass spectrometer (Agilent, 6130 Quadrupole MS, 1260 infinity LC, Santa Clara, California, USA) was utilized for the ESI measurements of 1. The drying gas was nitrogen at a 300 L \(\times\) h\(^{-1}\) flow rate. The sample solution (approx. 5 \(\times\) \(10^{-5}\) M) in acetonitrile was infused through a syringe pump directly into the interface at a flow rate of 0.4 mL min\(^{-1}\). The temperature of the source block was set to 120 °C and the interface to 150 °C. A capillary voltage of 2.0 kV was used in the positive scan mode, and low values of the cone voltage \((U_c = 5–10\) V\) were used to control the extent of fragmentation. The observed isotopic pattern of each compound perfectly matched the theoretical isotope pattern calculated from their elemental composition by using the MassLynx 4.1 program (Waters Corporation, Milford, Massachusetts, USA). ESI measurements of 3 were performed using an AmazonX (Bruker Daltonics, Bremen, Germany) ion trap mass spectrometer in positive mode in the mass range of 200–3000 Da. The sample solution (approx. 5 \(\times\) \(10^{-3}\) M) in DMF was infused through a syringe pump directly into the interface at a flow rate of 0.2 mL min\(^{-1}\). The ESI-MS conditions were as follows: capillary voltage, 2.5 kV; nitrogen drying gas, 10 L \(\times\) min\(^{-1}\), 250 °C. Data processing was performed by DataAnalysis software (Bruker Daltonik GmbH, Version 4.0 SP4, Bremen, Germany).

Synthesis of \([\text{Mo}_3(\text{Pd}(\text{dbbpy})_3]\]PF\(_6\) (I). A mixture of \([\text{Mo}_3\text{S}_4\text{Cl}_3(\text{dbbpy})_3]\]PF\(_6\) (0.2 g, 0.13 mmol) and \([\text{Pd}_2(\text{dba})_3] \times \text{CHCl}_3\) (0.07 g, 0.068 mmol) was stirred in CH\(_2\)Cl\(_2\) (20 mL) for 24 h. An excess of n-hexane was layered onto the resulting brown solution to give a brown product of 1 that was washed by n-hexane and diethyl ether. Yield: 0.133 g (54%).

IR (\(\nu\), cm\(^{-1}\)): 3395 w, 3158 m, 3123 m, 2960 s, 2903 s, 2869 s, 1626 s, 1618 s, 1549 m, 1460 (\([\text{Mo}_3\text{Pd}(\text{acac})_3(\text{OH})_3(\text{dbbpy})_3]\]PF\(_6\)), 1313 (\([\text{Mo}_3\text{Pd}(\text{acac})_3(\text{OH})_3(\text{dbbpy})_3]\]PF\(_6\)), 1277 (\([\text{Mo}_3\text{S}_4\text{OH}_3(\text{dbbpy})_3]\]PF\(_6\)) ppm. ESI-MSI (+, CH\(_3\)CN): \(m/z = 1671\) (\([\text{Mo}_3(\text{Pd}(\text{dba})_3]\]PF\(_6\)), 1437 (\([\text{Mo}_3\text{PdS}_2\text{Cl}_3(\text{dbbpy})_3]\]PF\(_6\)), 1313 (\([\text{Mo}_3\text{S}_2\text{Cl}_2(\text{OH})(\text{dbbpy})_3]\]PF\(_6\)), 1383 (\([\text{Mo}_3\text{Pd}_4(\text{OH})(\text{dbbpy})_3]\]PF\(_6\)), 1277 (\([\text{Mo}_3\text{S}_4(\text{OH})_3(\text{dbbpy})_3]\]PF\(_6\)).

Anal. Calc. for C\(_{71}\)H\(_{86}\)Cl\(_2\)F\(_2\)Mo\(_3\)N\(_6\)OPPdS\(_4\): C, 47.0; H, 4.8; N, 4.6%. Found: C, 46.7; H, 4.4; N, 5.0%.

Synthesis of \([\text{Mo}_3(\text{Pd}(\text{tu})_3]\]PF\(_6\) (2). A mixture of \([\text{Mo}_3\text{S}_4\text{Cl}_3(\text{dbbpy})_3]\]Cl (0.1 g, 0.74 mmol), \([\text{Pd}_2(\text{dba})_3] \times \text{CHCl}_3\) (0.038 g, 0.37 mmol), and thiourea (0.056 g, 0.74 mmol) in 20 mL of CH\(_2\)Cl\(_2\) was stirred for 24 h. An excess of hexane was layered onto the resulting brown solution to give a greenish-brown product of 2. Yield: 0.080 g (71%). The obtained analytical data nicely fit with previously published results [36].

Synthesis of \([\text{Mo}_3(\text{Pd}(\text{dba})_3]\]PF\(_6\) (3). A mixture of \([\text{Mo}_3\text{S}_4(\text{acac})_3(\text{py})_3]\]PF\(_6\) (0.2 g, 0.17 mmol) and \([\text{Pd}_2(\text{dba})_3] \times \text{CHCl}_3\) (0.089 g, 0.086 mmol) were stirred in CH\(_2\)Cl\(_2\)
(20 mL) for 24 h. An excess of $n$-hexane was layered onto the resulting brown solution to give a green-brown product of 3 that was washed by $n$-hexane and diethyl ether. Yield: 0.121 g (47%).

IR (ν, cm$^{-1}$): 2918 m, 1627 s, 1611 m, 1603 m, 1597 s, 1578 m, 1568 m, 1523 s, 1485 m, 1444 s, 1416 m, 1366 s, 1280 s, 1177 w, 1106 s, 1021 s, 1013 s, 975 w, 876 s, 838 s, 782 w, 755 w, 672 m, 622 m, 551 s, 540 s, 490 s, 425 s.

NMR 1H (400 MHz, CDCl$_3$, 293 K): δ = 9.58, 9.47 (6H, α-py), 8.15, 8.13, 8.10 (3H, γ-py), 7.80–7.30 (2H + 10H, dba; 6H, β-py), 7.03 (2H, dba) 5.36 (γ-CH, acac), 1.85 (CH$_3$, acac) ppm.

ESI-MSI (+, DMF): m/z = 1057.8 ([Mo$_3$Pd$_3$(acac)$_3$(py)$_3$]$^+$), 978.6 ([Mo$_3$Pd$_4$(acac)$_3$(py)$_2$]$^+$), 899.6 ([Mo$_3$Pd$_4$(acac)$_3$(py)$_2$]$^+$), 951.8 ([Mo$_3$S$_4$(acac)$_3$(py)$_3$]$^+$), 870.8 ([Mo$_3$S$_4$(acac)$_3$(py)$_2$]$^+$), 793.8 ([Mo$_3$S$_4$(acac)$_3$(py)$_2$]$^+$), 714.7 ([Mo$_3$S$_4$(acac)$_3$(py)$_2$]$^+$).

Anal. Calc. for C$_{47}$H$_{50}$(Mo$_3$N$_3$O$_2$P)$_3$: C, 39.0; H, 3.1; N, 3.3%.

Interaction of 1, 2, and 3 with P$_4$ in the presence of H$_2$O. A solution of P$_4$ (0.0025 g, 0.02 mmol) was added at room temperature to a solution of complex 1, 2, or 3 (0.02 mmol) in 1 mL of solvent (DMF, CH$_2$Cl$_2$, or THF). Then, H$_2$O (0.043 mL, 2.4 mmol) was added dropwise to the reaction mixture. After 12 h of stirring, TINO$_3$ (0.021 g, 0.08 mmol) was added. An analysis of the reaction mixture was provided by $^{31}$P NMR spectroscopy after each of the consequent steps.

Funding: This research was funded by the Russian Foundation for Basic Research (grant numbers 19-33-50136 and 18-33-20056) and by the Russian Government Program of Competitive Growth of Kazan Federal University (Reg. Nr. AAAA-A19-119053190012-8) and the Government assignment for FRC Kazan Scientific Center of RAS (Reg. Nr. AAAA-A18-118041760011-2).

Informed Consent Statement: Informed consent was obtained from all subjects involved in the study.

Data Availability Statement: Data sharing is not applicable to this article.

Acknowledgments: We acknowledge the financial support from the Russian Foundation for Basic Research (grants 19-33-50136 and 18-33-20056). The authors are thankful to the Russian Government Program of Competitive Growth of Kazan Federal University for performing of the NMR experiments in KFU and to the Government assignment for FRC Kazan Scientific Center of RAS for supporting this research activity dealing with the synthesis of the cluster complexes and phosphorus derivatives. The authors also gratefully acknowledge the CSF-SAC FRC KSC RAS for providing necessary facilities to carry out this work.

Conflicts of Interest: The authors declare no conflict of interest.

Sample Availability: Samples of the compounds 1–3 are available from the authors.
