**Abstract**

We use integer programming (IP) and constraint programming (CP) to search for sets of mutually orthogonal latin squares (MOLS). We improve the performance of the solvers by formulating an extended symmetry breaking method and provide an alternative CP encoding which performs much better in practice. Using state-of-the-art solvers we are able to quickly find pairs of MOLS (or prove their nonexistence) in all orders up to and including eleven. We also analyze the effectiveness of using CP and IP solvers to search for triples of MOLS and estimate the running time of using this approach to resolve the longstanding open problem of determining the existence of a triple of MOLS of order ten.

**Introduction**

A latin square of order \( n \) is an \( n \times n \) array, \( L \), of symbols \( \{0, 1, \ldots, n-1\} \) in which each symbol appears exactly once in each row and column. The entry in row \( i \) and column \( j \) of a square \( L \) is denoted \( L_{ij} \). Two latin squares of the same order, \( L \) and \( M \), are said to be orthogonal if there is a unique solution \( L_{ij} = a, M_{ij} = b \) for every pair of \( a, b \in \{0, 1, \ldots, n-1\} \). A set of \( k \) latin squares of order \( n \), is called a set of mutually orthogonal latin squares (MOLS) if all squares are pairwise orthogonal—in which case we label the system as \( k \) MOLS(\( n \)).

There is a long history of using automated reasoning tools like constraint and integer programming solvers to search for and construct latin squares (Gomes 2000). In this project we use off-the-shelf constraint programming (CP) and integer programming (IP) solvers to find mutually orthogonal latin squares (or disprove their existence) in all orders up to and including eleven. We also develop two main improvements to the IP and CP models originally described by Appa et al. (Appa, Magos, and Mourtos 2006). First, we improve the constraint programming model by using indexing constraints to encode orthogonality, which performed significantly better than the standard constraint programming encoding—using a CP solver we were able to find or prove the nonexistence of \( 2 \) MOLS(\( n \)) for \( n \leq 11 \) with our improved encoding compared to \( n \leq 8 \) with the usual encoding. Our improved constraint programming formulation is described below. Table 1 compares the running times across all three models encoding the \( 2 \) MOLS(\( n \)) problem, and shows the superiority of this encoding. Second, we developed an improved symmetry breaking method (described below) that removes more symmetry from the search space than the “domain reduction” symmetry breaking method used in previous searches (Appa, Magos, and Mourtos 2006; Appa, Mourtos, and Magos 2002). Our new symmetry breaking method reduces the amount of symmetry present in the \( k \) MOLS(\( n \)) search by an exponential factor in \( n \) when compared with domain reduction symmetry breaking. The new symmetry breaking method performs well in practice, particularly with the integer programming model—using an IP solver we were able to find or prove the nonexistence of \( 2 \) MOLS(\( n \)) for \( n \leq 10 \) with our improved symmetry breaking compared to \( n \leq 8 \) with domain reduction symmetry breaking.

**Constraint and Integer Programming Models**

Let \( X \) and \( Y \) be two mutually orthogonal latin squares of order \( n \) with entries \( X_{ij} \) and \( Y_{ij} \) for \( 0 \leq i, j < n \). One method of approaching the \( 2 \) MOLS(\( n \)) problem is to express it as a pure binary linear program and use an integer programming (IP) solver to generate solutions (Dantzig 1963, §26.3.IV). Our IP model for a set of two mutually orthogonal latin squares contains the \( n^4 \) binary variables

\[
x_{ijkl} := \begin{cases} 1 & \text{if } X_{ij} = k \text{ and } Y_{ij} = l \\ 0 & \text{otherwise} \end{cases}
\]

for all \( i, j, k, l \in \{0, 1, \ldots, n-1\} \). The latin and orthogonality constraints are expressed as six sets of \( n^2 \) equalities grouped by which subscripts of \( x_{ijkl} \) are fixed. A CP solver allows a more natural formulation of the \( 2 \) MOLS(\( n \)) problem using the \( 2n^2 \) integer-valued variables

\[
X_{ij} := \text{value of cell } (i, j) \text{ in square } X, \\
Y_{ij} := \text{value of cell } (i, j) \text{ in square } Y,
\]

where \( i, j, X_{ij}, Y_{ij} \in \{0, 1, \ldots, n-1\} \). The squares \( X \) and \( Y \) can be forced to be latin squares via “AllDifferent” constraints which specify that the rows and columns of the squares each contain different values. Appa et al. provide an encoding of orthogonality by defining \( Z_{ij} := X_{ij} + nY_{ij} \) and imposing AllDifferent(\( Z_{ij} \forall i, j \)); we call this the CP-linear encoding.
We call this the CP-index encoding and altogether it uses
within each square can be permuted independently and the
where \( Z \)
the first column permutation of \( X \) is in lexicographic order and the first column of \( Y \) is in lexicographic order. The \emph{first column permutation} of \( Y \) is \( \rho(i) = Y_{i0} \). We prove that any pair of orthogonal latin squares is isomorphic to a pair \((X, Y)\) in standard form where \( \rho \)'s disjoint cycles, when
listed in lexicographic order, are from shortest to longest. This fact applies equally well to a set of \( k \) MOLS\((n)\), and implies that we can restrict the first column of the second square to be in a fixed set of canonical representatives (one from each cycle type). Figure 1 contains a plot comparison of the running times observed by using each of our available symmetry breaking methods. More detailed timings, proofs and complete implementations of our programs can be found at https://github.com/noahrubin333/CP-IP.
