The radial-breathing-like phonon modes (RBLMs) of the double-walled carbon nanotubes are studied in a simple analytical model, in which the interaction force constants (FCs) can be obtained analytically from the continuous model. The RBLMs frequencies are obtained by solving the dynamical matrix, and their relationship with the tube radii can be obtained analytically, offering a powerful experimental tool for determining precisely the radii of the multi-walled carbon nanotubes.

\[ H^S = \frac{1}{2} m \dot{r}^2 + \frac{1}{2} m \omega_{RBM}^2 r^2. \]  (1)

Here the superscript \( S \) means the SWNT. \( m = (2\pi rh) n_s m_c \) is the mass of the cylinder, \( n_s \) is the mean surface density of carbon atoms on the tube wall, and \( m_c \) is the mass of carbon atom. \( \dot{r} \) is the time derivative of the radius, and \( \omega_{RBM} \) is the vibration frequency of the RBM mode. It is well known that the RBM frequency of the SWNT satisfies a simple relationship with the nanotube radius,

\[ \omega_{RBM} = D/ (2r_0), \]  (2)

where \( D \) keeps a constant for any kind of SWNTs and \( r_0 \) is the equilibrium radius of the SWNT. Thus we have

\[ H^S = \frac{1}{2} m \dot{r}^2 + \frac{1}{8} m D^2 \left( \frac{r}{r_0} \right)^2. \]  (3)

For the DWCNTs, the Hamiltonian can be further written as\(^{13}\)

\[ H^D = H_{in}^S + H_{out}^S + V_{io}, \]  (4)

where \( H_{in}^S \) and \( H_{out}^S \) are the Hamiltonians of the inner and outer SWNTs, respectively, with their radii as \( r_1 \) and \( r_2 \). And \( V_{io} \) is the interaction potential between the inner and outer tubes.

In this work, we assume the interaction between inner- and outer-tube atoms can be described by the Lennard-Jones (LJ) potential,

\[ u(x) = 4\varepsilon \left[ \left( \frac{\sigma}{x} \right)^6 - \left( \frac{\sigma}{x} \right)^{12} \right], \]  (5)

with parameters, \( \varepsilon = 2.964 \) meV and \( \sigma = 3.407 \) Å\(^{13}\). Based on our previous work\(^{13}\), when the tube height is large enough, the interaction potential can be written as

Right now, the double-walled carbon nanotubes (DWCNTs) become an important research subject after they are successfully synthesized by catalytic chemical vapor deposition\(^{1,2,3}\) and the thermal conversion of C\(_60\) encapsulated in single-walled carbon nanotubes (SWCNTs)\(^4\). Many researches\(^5,6,7,8,9,10,11,12\) have shown that there exists a kind of radial motion in the DWCNTs similar to the radial breathing modes (RBMs) in the SWCNTs, called as the radial breathing-like modes (RBLMs). But their relationship with the tube radii is still an open question, which is the most important for understanding the experimental RBLMs. In some publications\(^5,7,8,9,10,11,12\), the force constants are computed numerically, making the relationship between the RBLM frequencies and the tube radii unclear. Dobardžić et al. suggested a simple analytical model\(^13\), considering the tube walls as coupled oscillators, and the FC values of the coupled oscillators are determined by a fitting to the experimental B\(_2\) graphite phonon frequency of 127 cm\(^{-1}\). With this model, they have successfully calculated the RBLM frequencies of the DWCNT.

In this work, we have investigated further the RBLMs of the DWCNTs, using the simple analytical model\(^13\), and assuming the carbon atoms on the nanotube wall are distributed continuously, which has been used in a lot of systems\(^14,15,16,17,18,19\). Based on the continuum model in Ref.\(^{19}\), we have derived a set of formulae to describe the interaction between an infinite length tube and an atom in any place. With these formulae, the force constants between the inner and outer tubes can be obtained analytically, and furthermore, an accurate relationship between the RBLM frequencies and the tube radii has been obtained. Our final results only involve a few basic parameter values relying on the nanotubes structure and the parameters of Lennard-Jones (LJ) potential.

Now, let us introduce the simple analytical model. For the RBLMs, the only degree of freedom is the motion along the radial direction of the tube, so we can simply consider the RBLMs as the motion of a harmonic oscillator. A segment of SWNT can be described as a smooth cylinder with its radius and height represented by \( r \) and \( h \). Then its Hamiltonian can be written as:
$$V_{io} = N_{in} \ast 3\pi r_1\varepsilon_\sigma \ast V_{KERNEL} + N_{out} \ast 3\pi r_2\varepsilon_\sigma \ast V_{KERNEL},$$ \hspace{1cm} \text{(6)}$$

where

$$V_{KERNEL} = \left[ -\frac{\sigma^6}{(4r_1r_2)^{\frac{5}{2}}} I_5 + \frac{21}{32} \frac{\sigma^{12}}{(4r_1r_2)^{\frac{11}{2}}} I_{11} \right],$$ \hspace{1cm} \text{(7)}$$

$$I_{2k+1} = \int_0^{\frac{\pi}{2}} \frac{dt}{(a^2 + \sin^2 t)^{\frac{1}{2}}}, \quad a^2 = \frac{(r_1 - r_2)^2}{4r_1r_2}. \hspace{1cm} \text{(8)}$$

Now we can obtain the dynamical matrix analytically,

$$F = \begin{bmatrix} \frac{1}{m_{out}} \frac{\partial^2 V_{io}}{\partial r_1^2} & \frac{1}{m_{out} m_{in}} \frac{\partial^2 H^0}{\partial r_1 \partial r_2} \\ \frac{1}{m_{out} m_{in}} \frac{\partial^2 H^0}{\partial r_2 \partial r_1} & \frac{1}{m_{in}} \frac{\partial^2 V_{io}}{\partial r_2^2} \end{bmatrix} = \begin{bmatrix} \left(\omega_{RBM}^{out}\right)^2 & 0 \\ 0 & \left(\omega_{RBM}^{in}\right)^2 \end{bmatrix} + \begin{bmatrix} K_{11} & K_{12} \\ K_{21} & K_{22} \end{bmatrix}. \hspace{1cm} \text{(10)}$$

Here,

$$K_{11} = \frac{1}{m_{out}} \frac{\partial^2 V_{io}}{\partial r_1^2} \approx C_0 \left[ \frac{88}{3} s_0^2 - \frac{20}{3} s_6 - \frac{44}{3} \beta s_0^{11} - \frac{20}{3} s_0 s_5 \right] s_1 - \left( \frac{33}{10} s_0^{10} - \frac{5}{4} s_0^4 \right) s_1^2 + \ldots, \hspace{1cm} \text{(11a)}$$

$$K_{21} = K_{12} = \frac{1}{m_{out} m_{in}} \frac{\partial^2 V_{io}}{\partial r_1 \partial r_2} \approx C_0 \left[ \frac{88}{3} s_0^2 + \frac{40}{3} s_6 + \left( \frac{11}{30} s_0^{10} + \frac{5}{12} s_0^4 \right) s_2 + \ldots \right], \hspace{1cm} \text{(11b)}$$

$$K_{22} = \frac{1}{m_{in}} \frac{\partial^2 V_{io}}{\partial r_2^2} \approx C_0 \left[ \frac{88}{3} s_0^2 - \frac{40}{3} s_6 + \frac{44}{3} \beta s_0^{11} - \frac{20}{3} s_0 s_5 \right] s_2 - \left( \frac{33}{10} s_0^{10} - \frac{5}{4} s_0^4 \right) s_2^2 + \ldots, \hspace{1cm} \text{(11c)}$$

where $s_0 = \frac{e}{m_e}$, $s_1 = \frac{\varepsilon}{m_e}$, and $s_2 = \frac{\sigma}{m_e}$. $d_0 = r_1 - r_2$ is the distance between the inner and outer tubes. Above formulae are suitable for any tube-tube distance.

Assuming $d_0 = 3.4 \AA \approx \sigma$, which is equal to the inter-layer spacing of graphite, we can further get

$$K_{11} = \frac{1}{m_{out}} \frac{\partial^2 V_{io}}{\partial r_1^2} \approx C_0 \left[ 16 - 8s_1 - \frac{11}{2} s_2^2 - \frac{11}{2} s_1^2 + \ldots \right], \hspace{1cm} \text{(12a)}$$

$$K_{21} = K_{12} = \frac{1}{m_{out} m_{in}} \frac{\partial^2 V_{io}}{\partial r_1 \partial r_2} \approx C_0 \left[ -16 + \frac{1}{20} s_1^2 + \frac{1}{20} s_2^2 + \ldots \right], \hspace{1cm} \text{(12b)}$$

$$K_{22} = \frac{1}{m_{in}} \frac{\partial^2 V_{io}}{\partial r_2^2} \approx C_0 \left[ 16 + 8s_2 - \frac{41}{20} s_2^2 + \frac{41}{40} s_1^2 + \ldots \right]. \hspace{1cm} \text{(12c)}$$

For the DWCNTs, when inner tube radius $r_2$ is larger than $(r_1 - r_2) \approx 3.4 \AA$, the $a^2 \leq \frac{1}{8}$, so we can use our series expression for the Eq. (8), and get

$$N_{in} = 2\pi r_2 n_\sigma h \text{ and } N_{out} = 2\pi r_1 n_\sigma h \text{ are the number of atoms of the inner and outer tube segment, respectively. } k \text{ is an integer.}$$
is always chosen as 225 cm\(^{-1}\) nm. By diagonalizing the
dynamical matrix of Eq. 10, the RBLM frequencies can be
obtained.

For example, the RBLM frequencies of (5, 5)@(10, 10)
DWCNT are calculated using above \(C_0\) and \(D\). Then one
can easily obtain \(\omega_{LF} = 173.9\) cm\(^{-1}\) and \(\omega_{HF} = 340.8\)
cm\(^{-1}\). And the corresponding RBM frequencies of (5, 5)
and (10, 10) SWNTs obtained by Eq. 2 are \(\omega_{(5,5)} = 331.9\)
cm\(^{-1}\) and \(\omega_{(10,10)} = 165.9\) cm\(^{-1}\). Thus the frequency
shifts of the RBLMs in the DWCNT are \(\Delta \omega_{LF}^i = \omega_{LF} - \omega_{(5,5)} = 8.0\) cm\(^{-1}\) and \(\Delta \omega_{HF}^i = \omega_{HF} - \omega_{(5,5)} = 8.9\)
cm\(^{-1}\), respectively.

To make a comparison, a first-principle calculation has
been performed on the (5, 5)@(10, 10) DWNT to check the
validity of our method. A supercell geometry was
adopted so that the DWCNT is aligned in a hexagonal ar-
ray with nearby DWCNT center distance of 25 Å, which
is found to be larger enough to prevent the tube-tube in-
teractions. The K-points sampling in the reciprocal space
is a uniform grid \(1 \times 1 \times 24\) along the nanotube axis (Z di-
rection) in our calculations. After structure relaxation on
both of the lattice constant along the tube axis and the
atomic positions, the optimal structure is obtained when
the residue forces acting on all the atoms were less than
0.01 eV/Å. The final dynamical matrix is constructed
using cumulant force-constant (CFC) method\(^{20,21}\). Be-
cause of the advantage of the CFC method in dealing
with the low frequency part of the phonon dispersion,
only a small supercell \((1 \times 1 \times 2)\) is sufficient to calcu-
late accurately the phonon modes on the \(\Gamma\) point and the
X point. Our \textit{ab initio} calculations were performed
using highly accurate projected augmented wave (PAW)
method\(^{22}\), implemented in the Vienna \textit{ab initio} simula-
tion package (VASP) package\(^{23}\). They are based on the
density-functional theory in the local-density approxima-
tion (LDA).

The obtained phonon dispersion curves and the den-
sity of states for the (5, 5)@(10, 10) DWCNT are shown in
Fig. 1, in which the low-frequency dispersions are very
well reproduced. Its RBLM frequencies can be
determined by analysis of the normal modes, which are
\(\omega_{LF}^{ab} = 182.2\) cm\(^{-1}\) and \(\omega_{HF}^{ab} = 354.6\) cm\(^{-1}\). The
RBM frequencies of (5, 5) and (10, 10) SWNTs are
also calculated by the same \textit{ab initio} method under the
same calculation conditions as the DWCNT, which
are \(\omega_{(5,5)}^{ab} = 343.8\) cm\(^{-1}\) and \(\omega_{(10,10)}^{ab} = 173.6\) cm\(^{-1}\).
Then, the corresponding frequency shifts of them in
the DWCNT are \(\Delta \omega_{LF}^{ab} = \omega_{LF}^{ab} - \omega_{(5,5)}^{ab} = 8.6\) cm\(^{-1}\)
and \(\Delta \omega_{HF}^{ab} = \omega_{HF}^{ab} - \omega_{(5,5)}^{ab} = 10.8\) cm\(^{-1}\), respectively.
These results are consistent with our above obtained re-
results. The residual difference can be further minimized
by adopting the first-principle tube radii of \(R_{(5,5)} = 3.411\)
Å and \(R_{(10,10)} = 6.766\) Å, and the first-principle RBM
frequencies of the SWNTs in the dynamical matrix of
Eq. 10. By this way, the new frequency shifts obtained
by our analytical method will be \(\Delta \omega_{LF}^{ab} = 9.0\) cm\(^{-1}\) and
\(\Delta \omega_{HF}^{ab} = 10.3\) cm\(^{-1}\), agreeing very well with above first-
principle values.

Our approach can be further applied to the multi-
walled carbon nanotubes (MWCNTs). Here we take a
3-layer MWCNT as an example. Again, we can write
the system Hamiltonian as

\[
H^T = \sum_{i=1}^{3} H_i^S + \sum_{i \neq j} V_{ij},
\]  

where \(H_i^S\) is the Hamiltonian of the \(i\)th layer, and \(V_{ij}\)
is the interaction potential between the \(i\)th and the \(j\)th
layer nanotubes. And the radius of the \(i\)th layer is repre-
sented by \(r_i\) with \(r_1 > r_2 > r_3\). So, its dynamical matrix
can be written as:
where $K_{ij}^{\alpha\beta}$ means the $(\alpha, \beta)$ element of the $K$ matrix, which comes from the interaction between the $i$th and the $j$th layer tubes. If condition $a_{13}^2 = \frac{\left| r_{13} - r_{23} \right|^2}{4r_{13}r_{23}} \ll 1$ can be satisfied, the Eq. (11) can also be used to get the force constants between the 1st and the 3rd layer tubes. So using Eq. (11), the force constants between any two different layer tubes can be obtained easily. Here, for the 3 layers MWNT, we use $d_0 = 6.8 \text{ Å}$ as the distance between the 1st and the 3rd layer tubes, then Eq. (14) is fully determined.

To examine the precision of our result, we compare them with other numerical ones. The RBLM frequencies as a function of the outer tube radius for $(n, n)@ (n + 5, n + 5)@ (n + 10, n + 10)$ MWCNTs are plotted in Fig. 2 (For comparison, please see figure 5 of Ref. 12). From Fig. 2, it is found that our results match Ref. 12 very well, and the residual difference may come from the choice of some parameters, e.g., $D$, $d_0$ and $n_\sigma$. In fact, if we only slightly adjust both of $D$ and $C_0$, our RBLM frequencies can match all the other publications perfectly.

![FIG. 2: (Color online) Dependence of the RBLM frequencies on the outermost tube radius for 3 layer MWCNTs, i.e., $(n, n)@ (n + 5, n + 5)@ (n + 10, n + 10)$. The highest (HF), the middle (MF) and the lowest (LF) RBLM are plotted.]

Furthermore, we show the dependence of the RBLM frequencies on the number of layers in Fig. 3, in which the radius of the innermost tube is fixed at 30Å. This result matches the Fig. 6 of Ref. 12 perfectly. Based upon Fig. 3, a new method to determine the number of layers for the MWCNTs can be proposed, i.e., if the position of the lowest RBLM for a MWNT is obtained, one can easily find out how many layers are present in the MWCNT by comparing the experimental data with Fig. 3.

![FIG. 3: (Color online) Dependence of the RBLM frequencies on the layer number. Here, the radius of the innermost tube is fixed at 30 Å.]

Now we would like to illustrate the application of our approach. In Ref. 8, the Raman investigation of the DWCNTs prepared from thermal conversion of C$_{60}$ encapsulated in the SWCNTs has been reported, in which the Eq. (24), suitable only to the SWCNTs, was used to obtain the tube radii. Now we used our approach to determine the inner tube radius and the tube-tube distance. Here we choose a pair of experimental data from Ref. 8, $\omega_{LF} = 150 \text{ cm}^{-1}$ and $\omega_{HF} = 267 \text{ cm}^{-1}$. By Eq. (11), the high and low RBLM frequencies for different $r_2$ can be obtained at the certain $d_0$. Then comparing them with the experimental frequencies, we can get two different inner tube radii. In a real system, these two inner
tube radii value must be the same, and so we have to adjust the distance \( d_0 \) between the inner and outer tubes. Finally, a most reliable inner tube radius can be found. In Fig. 4, we finally set \( d_0 \) to be 3.558 Å, making the cross points of low and high frequencies with the experimental frequencies lie on one vertical line, from which a reliable inner tube radius of about 4.453 Å is obtained, i.e., \( R_{\text{in}} = 4.453 \) Å, and so \( R_{\text{out}} = 8.011 \) Å.

**FIG. 4:** (Color online) The Raman frequency vs the inner tube radius, which is obtained after adjusting the distance \( d_0 \) between the inner and outer walls to about 3.558 Å.

In summary, we presented an analytically solvable approach for the radial breathing-like phonon modes of the MWNTs, where the tube walls are treated as coupled oscillators, and the carbon atoms on nanotubes are distributed continuously. Then the force constants between inner and outer tubes, and the relationship of the RBLM frequencies with the tube radii can be obtained analytically. It is found that our obtained RBLM frequencies are well consistent with those in other publications and experiments. Finally, our result can be helpful to determine the radii of the DWCNTs and MWCNTs.
