Clinical usefulness of fluorodeoxyglucose–positron emission tomography/computed tomography and carbohydrate antigen 19–9 in patients with periampullary tumors

Jeong Eon Kim, Min Ho Shin, Nam Kyu Choi
Division of Hepatobiliary-Pancreas and Liver Transplantation Surgery, Department of Surgery, Chosun University Hospital, Gwangju, Korea

Purpose: The prognosis of periampullary cancer varies with its origin and early diagnosis influences outcome. Endoscopic ultrasound, computed tomography, fine needle aspiration, and fluorodeoxyglucose–positron emission tomography/computed tomography (\(^{18}\)FDG–PET/CT) are helpful for diagnosis. This study evaluates the diagnostic efficacy of \(^{18}\)FDG–PET for preoperative periampullary tumors.

Methods: A series of 100 patients undergoing \(^{18}\)FDG–PET/CT before surgical resection of periampullary tumors between March 2011 and February 2019 were enrolled. Maximum standardized uptake value (SUVmax) and carbohydrate antigen 19–9 (CA19–9) levels were compared with pathohistological confirmation of periampullary tumors.

Results: The SUVmax and uptake range varied with the origin of the periampullary tumors. The SUVmax was not available for 17 of the 42 pancreas tumors, three of 30 common bile duct tumors, and four of 18 ampulla of Vater tumors. The median SUVmax was 0.0 in benign tumors and 5.05 in malignant tumors. The mean SUVmax was 4.1 ± 5.6 in pancreatic tumors, 3.9 ± 2.4 in ampulla of Vater, and 6.0 ± 3.7 in common bile duct. The SUVmax was higher in common bile duct tumors than others. CA19–9 level was of diagnostic value in pancreatic tumor patients. The median CA19–9 levels were 7.64 U/mL (range, 2.71–45.05 U/mL) in benign tumors and 91.97 U/mL (range, 26.91–276.60 U/mL) in cancers patients.

Conclusion: Preoperative SUVmax and CA19–9 level were of diagnostic value for periampullary tumors originating in the pancreas.

Keywords: Pancreas neoplasm, Positron emission tomography computed tomography, Fluorodeoxyglucose F18, CA–19–9 antigen

INTRODUCTION

Periampullary tumors can arise from structures near the ampulla of Vater, pancreas, common bile duct, or duodenum, and the prog-
CT a noninvasive imaging method that identifies areas of increased glucose metabolism. The maximum standardized uptake value (SUVmax) of $^{18}$FDG-PET/CT is useful for the diagnosis of malignant tumors and metastatic disease [7]. Carbohydrate antigen 19-9 (CA19-9), pathologic T stage, tumor size, lymphovascular invasion, lymph node metastasis and resection margin are prognostic values in periampullary cancer, but most are available only after surgical resection [4]. Preoperative CA19-9 is useful for the diagnosis, determining tumor stage, monitoring therapeutic efficacy and detecting tumor recurrence [8]. Previous studies support the clinical utility of CA19-9 and PET/CT for the diagnosis of periampullary tumors and found correlation with pathological characteristics between SUVmax and CA19-9 level in pancreatic tumors [9,10]. This study was a retrospective review and analysis of the association of $^{18}$FDG-PET SUVmax, CA19-9 level, and the characteristics of pathologically confirmed periampullary tumors.

METHODS

A total of 100 patients with $^{18}$FDG-PET/CT for diagnosis of a suspected periampullary cancer between March 2011 and February 2019 at the Chosun University Hospital were enrolled, and 90 with histologically confirmed periampullary tumor after respective surgery were included in the analysis.

Patients’ work-up data from physical examinations, serologic studies, dynamic abdominopelvic CT and $^{18}$FDG-PET imaging were included on analysis. Eight patients with multiple metastases and two patients with carcinomatosis peritonei were excluded. Neuroendocrine tumor and intraductal papillary mucinous tumor neoplasm were included. Focal $^{18}$FDG uptake was considered positive for malignancy and the SUVmax was calculated. Medical history, complete blood cell count, serum chemistry (aspartate aminotransferase, alanine aminotransferase, total bilirubin, lipase, amylase, γ-glutamyl transpeptidase), serum tumor markers such as carcinoembryonic antigen (CEA), CA19-9, and α-fetoprotein (AFP) were available. The study was approved by the Institutional Review Board of Chosun University Hospital (IRB No. CHOSUN 2019-07-012) and performed in accordance with the principles of the Declaration of Helsinki. Written informed consent was waived.

$^{18}$FDG-PET/CT

The patients fasted for at least 6 hours before PET/CT scan and serum glucose was tested to confirm a concentration below 180 mg/day. Approximately 370 MBq $^{18}$FDG was administered via the antecubital vein 60 minutes before starting the PET/CT scan. Whole-body coverage included the subcranial to the upper thigh regions. PET acquisition was preceded by low-dose contrast non-enhanced CT followed by contrast-enhanced CT. A GE Healthcare Discovery ST (Chicago, IL, USA) was used for $^{18}$FDG-PET/CT imaging. The SUVmax indicates the maximum rate of metabolic glucose uptake. It was calculated in a circular region of interest in a transaxial image with the highest tumor uptake [10]. $^{18}$FDG is a positron-emitting isotope and malignant cells, which are more metabolically active than benign cells, accumulate more glucose than other tissues and become FDG-avid [11].

Statistical analysis

Variables were expressed as means ± standard deviation, medians, frequencies, and percentages.

The variables were analyzed by Kruskal-Wallis test. The diagnostic efficacy of $^{18}$FDG-PET/CT was indicated by the SUVmax observed by in periampullary cancers. The significance of differences in SUVmax and CA19-9 levels in benign and malignant tumor was determined with the Mann-Whitney nonparametric test when the values were not normally distributed. Statistical analysis was performed with SPSS version 25.0 (IBM Corp., Armonk, NY, USA).

RESULTS

Forty-seven of the 90 patients were included in the analysis; 43 were women and 47 were men with periampullary lesions. Forty-two of the tumors were in the pancreas, 30 were in the common bile duct, and 18 were in the ampulla of Vater (Table 1). The mean patient age was 67 ± 10.2 (range, 23–85 years). Resective surgery

| Location               | No. (%) |
|------------------------|---------|
| Ampulla of Vater       | 18 (20.0) |
| Common bile duct      | 30 (33.3) |
| Pancreas               | 42 (46.7) |
| Total                  | 90 (100) |

Table 1. Tumor location

| Procedure                        | No. (%) |
|----------------------------------|---------|
| PPPD                             | 59 (65.6) |
| Distal pancreatectomy            | 19 (21.1) |
| Total pancreatectomy             | 6 (6.7) |
| Ampullalectomy                   | 3 (3.3) |
| Cholecystectomy & CBD segmental resection, hepaticojejunostomy | 2 (2.2) |
| Palliative Roux-en Y GJ          | 1 (1.1) |
| Total                            | 90 (100) |

Table 2. Surgical procedures
was performed in all patients under general anesthesia. Pylo-
rus-preserving pancreatoduodenectomy was performed in 59 pa-
tients, 19 underwent distal pancreatectomy for pancreas tail can-
cers, and six underwent total pancreatectomy. Ampullectomy was
performed for three ampulla of Vater tumors. Two patients with
common bile duct tumors underwent bile duct resection and he-
paticojejunostomy and one patient underwent Roux-en Y anasto-
mosis and hepaticojejunostomy as palliative treatment (Table 2).

The mean of CA19-9 levels were 149.4± 237.4 U/mL in pancreas,
476.8± 1,433.0 U/mL in common bile duct, and 138.9± 136.8 U/
mL in ampulla of Vater tumors. AFP concentrations were 2.3± 1.6
ng/mL in pancreas, 1.9± 0.9 ng/mL in common bile duct, and 2.3
± 1.2 ng/mL in ampulla of Vater tumors. CT estimated size was 2.9
± 0.4 cm in pancreas, 1.6 ± 0.6 cm in common bile duct, and 0.6 ±
0.7 in ampulla of Vater tumors. The sizes determined by patholog-
ical evaluation were 3.1± 1.6 cm in pancreas, 3.0± 3.7 cm in com-
mon bile duct, 2.1 ± 1.2 cm in ampulla of Vater tumors. The mean
SUVmax was 4.1± 5.6 in pancreas, 6.0± 3.7 in common bile duct,
3.9± 2.4 in ampulla of Vater tumors (Table 3).

**Pathological diagnosis**

This study used American Joint Committee on Cancer Staging
Manual 8th edition. The pathology results are shown in Table 4. Pathological evaluation confirmed benign tumors in 17 patients
and malignant tumors in 70. Most benign lesions were in pancreas. Sixteen patients were TNM staging T1, 21 were T2, 29 were T3,
and four were T4. Three patients who underwent palliative surgery
had no pathological results (Table 4). The SUVmax (0.00 vs. 5.05)
and CA19-9 levels (7.64 vs. 91.97) were higher in patients with
malignant tumors than those with benign tumors. High CA19-9
levels and SUVmax were more common in patients with malig-
nancies (Table 5).

**DISCUSSION**

Periampullary tumors arise from the ampulla of Vater, pancreas,
Jeong Eon Kim et al. • 18FDG-PET/CT is useful for diagnosis of periampullary tumors

common bile duct, or duodenum. Those that arise in the pancreas are lethal, mortality closely parallels incidence. As most patients with pancreatic cancer remain asymptomatic until the disease reaches an advanced stage, there is a need for screening patients at risk of periampullary cancers. Imaging is very important in the workup of periampullary cancers and is noninvasive. Mohammad Alizadeh et al. [12] and Kamisawa et al. [13] both found that EUS and EUS-guided FNA had good diagnostic efficacy; 85% accuracy and high sensitivity for pancreatic cancer. Ibrahim et al. [14] reported that EUS-guided FNA was not sufficiently sensitive to identify low-grade intraductal papillary mucinous neoplasm, mucinous cystic neoplasm, or serous cystadenoma. However, its specificity was high enough to allow clinical identification of patients with high-grade dysplasia and/or coexistent carcinoma; EUS-guided FNA of pancreatic cysts does have real clinical value. The diagnostic accuracy of EUS-guided FNA makes useful as an adjunct to CT/MRI in determining the resectability of pancreatic cancer. However, EUS-guided FNA and ERCP are invasive and are associated with complications such as bleeding, tissue damage, and pancreatitis [15]. The use of PET and PET/CT for the initial staging and treatment planning has been valid [16]. The 18FDG uptake pattern can differentiate malignant from benign pancreatic masses, though a recent study failed to determine a sufficiently specific and sensitive SUVmax cutoff value because the pancreatic tuberculosis lesions had very high sensitive SUV max cutoff value because the pancreatic tuberculosis though a recent study failed to determine a sufficiently specific and pattern can differentiate malignant from benign pancreatic masses, imaging and treatment planning has been valid [16]. The 18FDG uptake pattern can differentiate malignant from benign pancreatic masses, though a recent study failed to determine a sufficiently specific and sensitive SUVmax cutoff value because the pancreatic tuberculosis lesions had very high 18FDG uptake [17]. Nasr Shaban [1] reported that 18FDG-PET/CT significantly increased the ability (P = 0.025) to detect of pancreatic cancer and extra abdominal recurrences. Sun et al. [10] found that SUVmax and CA19-9 significantly improved the sensitivity and specificity of the diagnosis of pancreatic cancer and evaluation of prognosis. Burge et al. [18] reported that inflammation increased FDG uptake in nonmalignant tissue, but was useful for surgical planning because it was able to detect metastasis. Jha and Bijan [19] reviewed the use of PET/CT in the evaluation of pancreatic cancer. The value of PET/CT for the of periampullary tumors has not been established. Akcam et al. [20] reported that PET/CT was not useful for the diagnosis of tumors originating in the ampullary region, and that low or normal SUVmax may indicate the presence of a periampullary mass. Verma et al. [15] reported that PET scans provide information on occult metastasis, but its clinical benefit in diagnosis is not yet established. In this study, the SUVmax was elevated in pathologically confirmed periampullary lesions but the mean SUVmax and range varied in different periampullary tumors depending on the origin. The SUVmax ranged from 0 to 25.6 for pancreatic tumors, and 0 to 7.1 in both ampulla of Vater and distal common bile duct. The SUVmax was higher in pancreatic tumors than other malignant periampullary tumors. However, 17 of the 42 pancreatic tumors, three of 30 common bile duct tumors, four of 18 ampulla of Vater tumors did not have SUVmax. CA19-9 is a diagnostic serum marker of pancreatic cancer in symptomatic patients and preoperative serum CA19-9 levels have prognostic value in pancreatic cancer patients with nonspecific symptoms or signs. However, malignancies have false-negative results because of genotype and increased false positive results in the obstructive jaundice [21]. In this study, CA19-9 levels were higher in patients with pancreatic lesions than in those with ampulla of Vater or common bile duct lesions.

The study limitations include limited data on the association of SUVmax and tumor differentiation, and not including perineural invasion and differentiation, but on pathological characteristics. The retrospective design was subject to patient selection bias. Finally, presurgical CA19-9 data was lacking.

In conclusion, preoperative PET/CT and SUVmax were useful for the evaluation of patients with periampullary tumors. Elevated SUVmax is associated with malignancy in common bile duct. CA19-9 was of diagnostic value in patients with pancreatic tumors. The SUVmax and CA19-9 level would be useful in planning surgical treatment of patients with periampullary tumors.

CONFLICT OF INTEREST

No potential conflict of interest relevant to this article was reported.
