The Ξ baryons are expected to be naturally narrower as compared to their nonstrange and strange counterparts since they have only one light quark and, thus, their decay involves producing either a light meson and doubly strange baryon or both meson and baryon with strangeness which involves, relatively, more energy. In fact, some Ξ’s have full widths of the order of even 10-20 MeV when, in principle, they have a large phase space to decay to some open channels. Such is the case of Ξ(1690), for which the width has been found to be of the order of 10 MeV in the latest BABAR and BELLE data. In this manuscript we study why some Ξ’s are so narrow. Based on a coupled channel calculation of the pseudoscalar meson-baryon and vector meson-baryon systems with chiral and hidden local symmetry Lagrangians, we find that the answer lies in the intricate hadron dynamics. We find that the known mass, width, spin-parity and branching ratios of Ξ(1690) can be naturally explained in terms of coupled channel meson-baryon dynamics. We find another narrow resonance which can be related to Ξ(2120). We also look for exotic states Ξ⁺ and Ξ⁻ but find none. In addition we provide the cross sections for ¯ KΛ, KΣ → πΞ which can be useful for understanding the enhanced yield of Ξ reported in recent studies of heavy ion collisions.

I. INTRODUCTION

Little is known about Ξ resonances [1] since it is difficult to produce them in the laboratory directly. There are limited facilities around the world which have antikaon beams and a beam of nonstrange nature on a nucleon leads to low yields of Ξ baryons as two pairs of strange quarks are required to be produced in this case. However, efforts are being made to improve this situation. For example, the photoproduction of Ξ’s on nucleons is being explored currently at the Jefferson laboratory [2] considering the possibility of the production of a hyperon resonance in the intermediate state, thus producing the strange quark pairs in two steps. Also, more information is expected to come in the future from the J-PARC [3] and PANDA [4] facilities.

In addition, studies made by BELLE [5] and BABAR [6] collaborations show that it is possible to extract useful information on this subject from rare processes too. Specifically, some intriguing findings related to the properties of Ξ(1690) have been reported in such studies. We find it useful to list these findings, and other relevant information on Ξ(1690), in a separate subsection dedicated to Ξ(1690) below.

A. Ξ(1690)

The first observation of Ξ(1690) in the KΣ invariant mass spectrum was reported in Ref. [7], where the mass and width were determined to be $M = (1694 \pm 6)$ MeV, $\Gamma = (26 \pm 6)$ MeV in the negatively charged channel and $M = (1684 \pm 5)$ MeV, $\Gamma = (20 \pm 4)$ MeV in the neutral channel. The spin-parity of this state was not determined in Ref. [7]. Although the mass values obtained by the latest investigations [5, 6] are not very different, the width of Ξ(1690) has been determined to be even narrower, of the order of 10 MeV [3, 6]. To mention explicit results, the BABAR collaboration deduced the mass and width of Ξ(1690) to be: $M = (1684.7 \pm 1.3^{+2.6}_{-1.0})$ MeV, $\Gamma = (8.1^{+3.5}_{-3.2} \pm 0.9)$ MeV [6], and the BELLE Collaboration reported: $M = (1688 \pm 2)$ MeV, $\Gamma = (11 \pm 4)$ MeV [5]. Both studies obtained spin-parity of this state as $1^-$. It was also found in Ref. [6] that a clear evidence for Ξ⁺(1690) is found in the $K^0\Lambda$ invariant mass spectrum but not in the $\pi^+\Xi^-$ spectrum. The information on the ratio of $\Xi^0(1690)$ to $K\Lambda$ and $K\Sigma$ has been updated in Ref. [6] to,

$$\frac{B(\Xi^0(1690) \rightarrow K^-\Sigma^+)}{B(\Xi^0(1690) \rightarrow K^0\Lambda)} = 0.50 \pm 0.26. \quad (1)$$

as compared to the value $(1.8 \pm 0.6)$ obtained from the older analysis of Ref. [7].

These properties are difficult to understand, for example, the narrow width of Ξ(1690) in spite of having a large phase space to decay to open channels, like, $\pi\Xi$ and $K\Lambda$. Similar is the case of the finding related to the suppressed decay to $\pi\Xi$, as compared to the decay to the $K\Lambda$ channel (as is evident from the difficulty in the identification of the signal of $\Xi^0(1690)$ in the $\pi^+\Xi^-$ spectrum of Refs. [5, 6]). A light quark pair production, within a naive quark model, is equivalently required in both cases (as can be seen in Fig. [1]). The branching fraction to the $K\Sigma$ and $K\Lambda$ channels (shown in Eq. [1]) is
The formalism of the present study is based on solving the Bethe-Salpeter equation in a coupled channel approach. To do this we consider all systems with strangeness −2 formed by a pseudoscalar/vector meson with an octet baryon: \( \pi \Xi, \eta \Xi, K \Sigma, K \Lambda, \rho \Xi, \omega \Xi, \phi \Xi, K^* \Sigma \) and \( K^* \Lambda \).

We obtain the amplitudes for different transitions among these channels using Lagrangians based on effective field theories. To determine the vector-meson–baryon interaction we use the formalism developed in our previous work [25]. A detailed analysis of the low energy vector meson interaction with octet baryons was carried out in Ref [25] by calculating \( s, t \) - and \( u \) -channel
diagrams and a contact interaction, using a Lagrangian invariant under the gauge transformations of the hidden-local symmetry. It was found that the contribution of all the diagrams is of comparable size and that the full (summed) amplitude depended on the total spin as well as the isospin of the system. Following Ref. [25], thus, we write vector-baryon (VB) amplitudes for each spin-isospin configuration as

\[ V^{I,S}_{VB} = V^{I,S}_{i,VB} + V^S_{u,VB} + V^S_{u,VB} + V^S_{CT,VB}. \]  

(2)

These amplitudes can be obtained from the general Lagrangian

\[ \mathcal{L}_{VB} = -g \left\{ \langle B \gamma_\mu [V^\mu_s, B] \rangle + \langle B \gamma_\mu B \rangle (V^\mu_s) \right\} + \frac{1}{4M} (F[B \sigma_\mu \nu V^\mu_w, B] + D[B \sigma_\mu \nu \{V^\mu_w, B\}]) + \langle B \gamma_\mu B \rangle (V^\mu_0) + \frac{g}{4M} \langle B \sigma_\mu \nu V^\mu_0 B \rangle, \]

(3)

where \langle \ldots \rangle refers to an SU(3) trace, the subscript 8 (0) on the meson fields denotes the octet (singlet) part of their wave function (relevant in case of \( \omega \) and \( \phi \), for which we assume an ideal mixing). \( V^{\mu \nu} \) represents the tensor field of the vector mesons,

\[ V^{\mu \nu} = \partial^\mu V^\nu - \partial^\nu V^\mu + ig [V^\mu, V^\nu], \]

and \( V^\mu \) and \( B \) denote the SU(3) matrices for the (physical) vector mesons and octet baryons

\[ V^\mu = \frac{1}{2} \begin{pmatrix} \rho^0 + \omega \sqrt{2} \rho^+ \sqrt{2} K^{*+} \\ \sqrt{2} \rho^- - \rho^0 + \omega \sqrt{2} K^{*0} \\ \sqrt{2} K^{*-} \sqrt{2} \bar{K}^{*0} \sqrt{2} \phi \end{pmatrix}, \]

(5)

and

\[ B = \begin{pmatrix} \frac{1}{\sqrt{6}} \Lambda + \frac{1}{\sqrt{2}} \Sigma^0 & \Sigma^+ & p \\ \Sigma^- & \frac{1}{\sqrt{6}} \Lambda - \frac{1}{\sqrt{2}} \Sigma^0 & n \\ \Xi^- & \Xi^0 & -\sqrt{\frac{2}{3}} \Lambda \end{pmatrix}. \]

(6)

In Eq. (3), the coupling \( g \) is related to meson decay constants as

\[ g = \frac{m}{\sqrt{2} f}, \]

and the constants \( D = 2.4, F = 0.82 \) and \( C_0 = 3F - D \) are such that the anomalous magnetic couplings of \( \rho \bar{N}N \), \( \omega \bar{N}N \) and \( \phi \bar{N}N \) vertices are correctly reproduced. These values have also been found useful in calculations of the magnetic moments of the baryons in Ref. [26].

Keeping in mind that the thresholds of different VB channels differ by \( \sim 200 \) MeV, which implies that the center of mass energies of the lighter VB channels can vary up to 200 MeV above the respective thresholds, we calculate all the amplitudes relativistically, following Refs. [27, 28].

We start the discussion on different amplitudes with the contact interaction which arises from the commutator part of the tensor field (Eq. (4)). The resulting amplitude has a form,

\[ V^S_{CT,VB} = -C^S_{CT,VB} \frac{g_1g_2}{2\sqrt{M_1M_2}} \left\{ -i \sigma \cdot \epsilon_2 \times \epsilon_1 \right\} \]

(8)

\[ + \frac{1}{E_2 + M_2} \left( -e_0^0 \sigma \cdot \bar{P}_2 \sigma \cdot \epsilon_2 + e_0^0 \sigma \cdot \bar{P}_2 \sigma \cdot \epsilon_1 \right) \]

\[ + \frac{1}{E_1 + M_1} \left( -e_2^0 \sigma \cdot \epsilon_1 \bar{P}_1 \sigma \cdot \epsilon_2 + e_2^0 \sigma \cdot \epsilon_1 \bar{P}_1 \sigma \cdot \epsilon_2 \right) \]

\[ - \frac{1}{2} \frac{E_1 + M_1}{E_2 + M_2} \left( \sigma \cdot \bar{P}_2 \sigma \cdot \epsilon_1 \bar{P}_1 \sigma \cdot \epsilon_2 \right) \left\{ \sqrt{M_1 + E_1} \sqrt{M_2 + E_2} \right\}, \]

where \( M_1, M_2, E_1, E_2, \bar{P}_1, \bar{P}_2 \) represent the mass, energy and the three-momentum of the baryon in the initial (final) state, respectively, and \( g_1 \) (\( g_2 \)) is related to the decay constant of the vector meson in the initial (final) state through Eq. (7). The values of the decay constants used in our work are: \( f_\rho = 93 \) MeV, \( f_\eta = 120.9 \) MeV, \( f_k = 113.46 \) MeV, \( f_\omega = 153.45 \) MeV, \( f_\phi = 168.33 \) MeV, \( f_{\bar{K}^*} = 159.96 \) MeV [29, 30]. In Eq. (8), \( e_1^0 (\epsilon_2^0) \) and \( \epsilon_1 (\epsilon_2) \) represent the temporal and the spatial part of the polarization four-vectors of the mesons in the initial (final) state, respectively, and \( C^S_{CT,VB} \) are isospin dependent coefficients whose values are given in the Appendix [A1] [A2] for the different relevant channels.

We recall that the main purpose of the present article is to study the formation of resonances in a coupled meson-baryon system. We are, thus, interested in low energy dynamics of such a system and, consider the s-wave contribution of different amplitudes. The s-wave part (\( l = 0 \)) of Eq. (8) gives

\[ V^{1,S}_{CT,VB} = -C^{1,S}_{CT,VB} \frac{g_1g_2}{2\sqrt{M_1M_2}} \left\{ -i \sigma \cdot \epsilon_2 \times \epsilon_1 + \frac{1}{E_1 + M_1} \left( -e_0^0 \sigma \cdot \epsilon_1 \bar{P}_1 \sigma \cdot \epsilon_2 + e_0^0 \sigma \cdot \epsilon_1 \bar{P}_1 \sigma \cdot \epsilon_2 \right) \right\}, \]

which is indicated by the superscript \( S \) representing the spin of the VB system (which coincides with the total angular momentum \( J \) of the system).

The amplitude of Eq. (9) is projected on the total spin half base, to get,

\[ V^{1,1/2}_{CT,VB} = C^{1,1/2}_{CT,VB} \frac{g_1g_2}{\sqrt{M_1M_2}} \left\{ \frac{1 + \frac{1}{E_1 + M_1}}{2m_1} \left( \frac{|\bar{K}_1|^2}{2m_1} - |\bar{K}_1||\bar{K}_2| 6m_2 \right) \right\}, \]

(10)

and in case of spin 3/2, we obtain

\[ V^{1,3/2}_{CT,VB} = -C^{1,3/2}_{CT,VB} \frac{g_1g_2}{2\sqrt{M_1M_2}} \left\{ \frac{1 + \frac{1}{E_1 + M_1}}{2m_1} \left( -\frac{4}{3} \frac{|\bar{K}_1||\bar{K}_2|}{3m_2} \right) \right\}. \]
In Eqs. (10) and (11) (and throughout this manuscript) \( m_1, m_2 \) and \( K_1, K_2 \) represent the masses and the three-momenta of the vector mesons in the initial and final state, respectively.

Using the Yukawa-type vertices obtained from Eq. (3), we deduce the s- and u-channel amplitudes by treating the vector mesons relativistically, and obtain,

\[
V_{s,\nu B}^I = \frac{g_1 g_2}{2 - M_z^2} \left\{ (\sqrt{s} + M_a) \left( c_0^I \left[ I_{i, f} + \frac{I_{i, f} K_2^0}{2 \sqrt{M_1 M_2}} \right] - c_1^I \left[ I_{i, f} + \frac{I_{i, f} K_1^0}{2 \sqrt{M_1 M_2}} \right] \right) \left( \frac{\sqrt{s} - m_i}{2 \sqrt{M_1 M_2}} \right) + (\sqrt{s} - M_a) \left( \frac{\sqrt{s} - m_i}{2 \sqrt{M_1 M_2}} \right) \right\},
\]

(12)

where \( M_x \) is the mass of the exchanged (octet) baryon, \( s \) and \( u \) are the Mandelstam variables, \( K_1^0 (K_2^0) \) is the energy of the incoming (outgoing) vector meson, \( I_{i, f}^I, I_{i, f}^s, I_{i, f}^t \) are the isospin coefficients for different channels whose products are given in the Appendix A in Tables A2 - A6. The definitions of \( V_{u, v} \) appearing in Eq. (13) are also given in Eqs. (A1 - A12), in Appendix B. Due to the kinematic dependence of the Mandelstam variable \( u \) on the incoming and outgoing momentum, the s-wave projection of the u-channel amplitude is done numerically. In case of the s-channel amplitude we can project Eq. (12) analytically on s-wave, which gives

\[
V_{s,\nu B}^S = \frac{g_1 g_2}{2 - M_z^2} \left\{ (\sqrt{s} + M_a) \left( c_0^S \left[ I_{i, f} + \frac{I_{i, f} K_2^0}{2 \sqrt{M_1 M_2}} \right] \left( I_{i, f} + \frac{I_{i, f} K_1^0}{2 \sqrt{M_1 M_2}} \right) - c_1^S \left( \frac{\sqrt{s} - m_i}{2 \sqrt{M_1 M_2}} \right) \right) \right\},
\]

(14)

which, in turn, on spin-half projection reduces to

\[
V_{s,\nu B}^{3/2} = \frac{g_1 g_2}{2 - M_z^2} \left\{ (\sqrt{s} + M_a) \left( \frac{|K_1| |K_2|}{3 m_1 m_2} \left( I_{i, f} + \frac{I_{i, f} K_2^0}{2 \sqrt{M_1 M_2}} \right) \left( I_{i, f} + \frac{I_{i, f} K_1^0}{2 \sqrt{M_1 M_2}} \right) - \frac{|K_2| |K_1|}{m_2} \left( \frac{K_2^0 + 2}{3} \right) \left( I_{i, f} + \frac{I_{i, f} K_2^0}{2 \sqrt{M_1 M_2}} \right) \right) \right\},
\]

(15)
For more details on the conventions/normalizations related to the polarization vectors used in our work, we refer the reader to Appendix [3].

Finally, the contribution of the \( t \)-channel amplitude is obtained as,

\[
V^t_{1, c_{VB}} = \frac{-m^2_{V, x}}{4fV_i fV_j} \left( \begin{array}{c} \epsilon_1 \cdot \epsilon_2 \left( 2\sqrt{s} - M_1 - M_2 + (M_1 - M_2) \frac{(m^2_1 - m^2_2)}{m^2_{V, x}} \right) \cdot C^t_{1, c_{VB}} \\ + \frac{M_1 + M_2}{2M} \left( 2\sqrt{s} - M_1 - M_2 - \frac{s - u}{2M} \right) C^t_{12, c_{VB}} + \frac{\sigma \cdot \vec{P}_2 \cdot \vec{P}_1}{(E_1 + M_1)(E_2 + M_2)} \left( 2\sqrt{s} + M_1 + M_2 \right) \right) \\
- \frac{M_1 + M_2}{2M} \left( 2\sqrt{s} + M_1 + M_2 + \frac{s - u}{2M} \right) C^t_{12, c_{VB}} \right) \\
+ \left( C^t_{1, c_{VB}} + \frac{M_1 + M_2}{2M} C^t_{12, c_{VB}} \right) \left( -2K_1 \cdot \epsilon_2 \left[ \epsilon_1 \cdot - \frac{\sigma \cdot \vec{P}_2 \cdot \vec{P}_1}{E_1 + M_1} - \frac{\sigma \cdot \vec{P}_2 \cdot \vec{P}_1}{E_2 + M_2} + \frac{\epsilon_2 \cdot \vec{P}_2 \cdot \vec{P}_1}{(E_1 + M_1)(E_2 + M_2)} \right] \right) \\
- \frac{2K_2 \cdot \epsilon_1}{E_1 + M_1} \left[ - \frac{\sigma \cdot \vec{P}_2 \cdot \vec{P}_1}{E_1 + M_1} - \frac{\epsilon_2 \cdot \vec{P}_2 \cdot \vec{P}_1}{(E_1 + M_1)(E_2 + M_2)} \right] \right) \\
\times \left( \frac{1}{\left( E_1 + M_1 \right) \left( E_2 + M_2 \right)} \right) C^t_{12, c_{VB}} \right) \sqrt{\frac{M_1 + E_1}{2M_1}} \sqrt{\frac{M_2 + E_2}{2M_2}}
\]

where, \( m^2_{V, x} \) represents the mass of the exchanged meson, \( M_1(M_2) \), \( K_1(K_2) \) represent the mass and four-momentum of the meson in the initial (final) state, \( M \) denotes the SU(3) average mass which is taken as the nucleon mass, \( M_1(M_2) \) and \( E_1(E_2) \), \( \vec{P}_1(\vec{P}_2) \) represent the mass, energy and three-momentum of the baryon in the initial (final) state. The values of \( C^t_{1, c_{VB}} \) and \( C^t_{12, c_{VB}} \) are given in Table [X] \([8, 9, 10]\) in Appendix [3]. The s-wave projection of the \( t \)-channel amplitude is also done numerically, as in the case of the \( u \)-channel amplitude. We have followed the arguments of Ref. [31] for the numerical integration of the \( t \)-channel amplitude.

It can be seen that the amplitude of Eq. (16) is spin degenerate at low energies (where only \( \epsilon_1 \cdot \epsilon_2 \) spin structure contributes). This finding is in agreement with the results found in Refs. [18, 17]. However, such near degeneracy is removed by summing Eqs. (9), (13), (15) to the \( t \)-channel amplitude, giving rise to spin, isospin-dependent results. For a numerical comparison, we show the lowest order amplitudes obtained in the present work for the \( \rho \Xi \) and \( \bar{K}^* \Sigma \) channels, as examples, in Fig. 2 In fact, the general spin-dependence of the vector meson-baryon kernels may be expected since both the interacting hadrons have nonzero spin and similar masses. An alternative mechanism of breaking the spin-degeneracy has been suggested in Ref. [19]. Further, we go a step forward by including pseudoscalar-baryon as coupled channels in our formalism. The consideration of various contributions to the vector-baryon amplitudes, together with the treatment of the vector- and pseudoscalar-mesons at par in the coupled channel dynamics, is the distinct feature of our formalism.

A formalism to obtain the transition amplitudes be-

tween the pseudoscalar-baryon and the vector-baryon channels was developed in our previous work [32], where the Kroll-Ruderman term for the photoproduction of a pion was modified, in consistency with the vector meson dominance phenomenon, by replacing the photon by a vector meson. The deduction was extended to the SU(3) case in Ref. [32] to obtain a general Lagrangian for the transitions among pseudoscalar-baryon (PB) and vector-

FIG. 2: A comparison of the lowest order \( \rho \Xi \) and \( \bar{K}^* \Sigma \) amplitudes (Eq. (2)) for different spin-isospin configurations.
baryon (VB) channels

\[ \mathcal{L}_{PB} = \frac{-igKR}{2f_F} \left\{ F'(B \gamma_5 \gamma_5 [(P, V^\mu), B]) + D'(B \gamma_\mu \gamma_5 [(P, V^\mu), B]) \right\}, \]  

where \( F' = 0.46, D' = 0.8 \) reproduce the axial coupling constant of the nucleon: \( F' + D' \approx g_A = 1.26 \) [32].

In the present work we need the transition amplitudes between pseudoscalar-baryon and vector-baryon channels with strangeness \( |S| \). We obtain them using Eq. (17)

\[ V_{PB}^{I,I} = -ig_{PB}^{I} \frac{g_{KR}}{2\sqrt{FP}} \left\{ \left( \frac{\bar{P}_1 \cdot \bar{P}_2}{E_1 + M_1} + \frac{\bar{P}_1 \cdot \bar{P}_2}{E_2 + M_2} \right) \right\}, \]  

where \( g_{KR} \) is the Kroll-Ruderman coupling [32, 34] obtained from the lowest order chiral Lagrangian [35, 36].

The resulting s-wave amplitudes are consistent with those obtained earlier in Ref. [12].

\[ V_{PB}^{1/2} = -\frac{C_{PB}^{I}}{4f_1f_2} \left( \frac{M_1 + E_1}{M_1 + E_2} \right) \sqrt{\frac{M_1 + E_1}{M_2 + E_2}} \]  

where \( M_1, E_1 \) represent the mass and energy of the baryon in the initial (final) state, respectively, and \( f_1, f_2 \) is the decay constant of the meson in the initial (final) state. We do not give the values of \( C_{PB}^{I} \) here since they are same as those given in Ref. [12].

\[ \Gamma_{PB} = \frac{1}{2} \left( u_i \partial^\mu u + u \partial^\mu u_i \right), \]  

where \( U = u^2 = \exp \left( i \frac{P}{f_P} \right) \).

As defined earlier, \( f_P \) in Eq. (24) is the pseudoscalar decay constant, and \( P \) is

\[ P = \begin{pmatrix} \pi^0 + \frac{1}{\sqrt{2}} \eta & \sqrt{2} \pi^+ & \sqrt{2} K^+ \\ -\sqrt{2} \pi^- & -\pi^0 + \frac{1}{\sqrt{2}} \eta & \sqrt{2} K^0 \\ \sqrt{2} K^- & -\sqrt{2} K^0 & -\frac{2}{\sqrt{3}} \eta \end{pmatrix} \]

The resulting s-wave amplitudes are consistent with those obtained earlier in Ref. [12].

\[ V_{PB}^{3/2} = -\frac{C_{PB}^{I}}{4f_1f_2} \left( \frac{M_1 + E_1}{M_1 + E_2} \right) \sqrt{\frac{M_1 + E_1}{M_2 + E_2}} \]  

where \( G \) is a loop of two hadrons which is divergent in nature. It is possible to evaluate the loop function by using the dimensional regularization or with a three-momentum cutoff. In the former case, the subtraction constants can be fixed to have natural values following Refs. [16, 39, 40], to ensure the interpretation of the resonances found in the calculations as those arising from the dynamics of the system. In the latter case, a cutoff parameter \( \Lambda \) is used to regularize the loop function using a Gaussian form factor as

\[ G_i(\sqrt{s}) = \int_0^{d^3q} \frac{1}{(2\pi)^3} \frac{2M_i}{E_{2i}(\vec{q})} e^{-[(\vec{q}^2 - \vec{q}_{i, on}^2)/\Lambda^2]}, \]  

where the subscript \( i \) is the label for the \( i \)-th channel, \( E_{2i} \) and \( g_{q_{i, on}} \) are the energies of the two particles in the channel, \( M_i \) is the mass of the propagating baryon and, \( q_{i, on} \) is the three momentum of the relative motion of the particles in the intermediate state when they are on mass shell. We have calculated the amplitudes using both methods and find that the results obtained and conclusions are very similar. In the following we show the results obtained by calculating the loop function using Eq. (27) with \( \Lambda = 800 \) MeV, although, later on, we will present the values of the poles found within the dimensional regularization scheme too.
It is important to add here that we take into account the fact that the width of some vector mesons, like $K^*$ and $\rho$, is considerably large. To do this we convolute the loops over the varied mass of these mesons following Ref. [15],

$$\tilde{G}_i(\sqrt{s}) = \frac{1}{N} \int \frac{d\tilde{m}^2}{(m-2\Gamma)^2} G_i(\sqrt{s}) \times \text{Im} \left\{ \frac{1}{\tilde{m}^2 - m^2 + i\Gamma(\tilde{m})} \right\} \tag{28}$$

where $G_i(\sqrt{s})$ is calculated using Eq. (27) and where

$$N = \int \frac{d\tilde{m}^2}{(m-2\Gamma)^2} \left( -\frac{1}{\pi} \right) \text{Im} \left\{ \frac{1}{\tilde{m}^2 - m^2 + i\Gamma(\tilde{m})} \right\},$$

with

$$\Gamma(\tilde{m}) = \Gamma_{\text{meson}} \left( \frac{m^2}{\tilde{m}^2} \right)^{\frac{1}{2}} \left( \frac{m^2 + m_\rho^2 - m_\omega^2}{2\tilde{m}^2} \right)^{\frac{3}{2}} + \frac{m - m_d - m_d'}{\tilde{m}}.$$

In the above equation, $m_d, m_d'$ denote the masses of the decay products of the vector mesons, i.e., pion masses in case of $\rho$, and kaon and pion mass in case of $K^*$. We use $\Gamma_\rho$ and $\Gamma_{K^*}$ as 149.4 MeV and 50.5 MeV, respectively. Thus, for the channels involving the $\rho$ and the $K^*$ mesons, we use Eq. (28) to solve the Bethe-Salpeter equation (Eq. (26)).

To search for resonances/bound states we need to obtain the $T$-matrix of Eq. (26) in the complex energy plane, for which we calculate the loop function in the first (I) and second (II) Riemann sheet as [33, 11]:

$$G_i(\sqrt{s}) = \begin{cases} G^{I\text{I}}_i(\sqrt{s}), & \text{for } \text{Re}\{\sqrt{s}\} < (m_i + M_i) \\ G^{I\text{I}}_i(\sqrt{s}), & \text{for } \text{Re}\{\sqrt{s}\} \geq (m_i + M_i) \end{cases}$$

where

$$G^{I\text{I}}_i(\sqrt{s}) = G_i(\sqrt{s}) \tag{29}$$

$$G^{I\text{I}}_i(\sqrt{s}) = G^{I\text{I}}_i(\sqrt{s}) - 2i\text{Im}\{G^{I\text{I}}_i\} \tag{30}$$

with $(m_i + M_i)$ being the threshold of the $i$th-channel. If a pole appears in the complex plane, it can be seen in the complex amplitude for all the channels. Depending on the threshold of a given channel, the pole can appear below or above the threshold (i.e., on the corresponding first or second Riemann sheet of that channel).

III. RESULTS AND DISCUSSIONS

A. Isospin = 1/2, Spin = 1/2 and Parity = -1

We begin the discussion of the results by showing the squared amplitudes for different coupled channels in the isospin 1/2, spin 1/2 configuration in Fig. 3. It can be seen from Fig. 3 that a clear narrow peak is present around 1690 MeV in all the channels except in $\pi\Xi$. This peak corresponds to a pole in the complex plane (shown in Fig. 4) at

$$M - i\Gamma/2 = 1687 - i2 \text{ MeV.} \tag{31}$$

This pole position is in good agreement with the recent determination of mass and width of $\Xi(1690)$ by the BABAR Collaboration: $M = (1684.7 \pm 1.3^{+2.2}_{-1.6})$ MeV,
$\Gamma = (8.1^{+3.9+1.0}_{-3.5-0.9})$ MeV \cite{4} and those determined by
the BELLE Collaboration: $M = (1688 \pm 2)$ MeV, $\Gamma = (11 \pm 4)$ MeV \cite{5}. The spin-parity 1/2$^-$ also coincides with the experimental data analysis of Ref. \cite{6}. The full
width of 4 MeV in Eq. (31) is a bit larger than the value $\sim 1$ MeV obtained in Ref. \cite{10}. This is because the couplings of the vector-baryon channels pushes the pole to slightly lower energies, hence, bringing it slightly closer to the $\bar{K}A$ channel. Another finding is that in our work, where we insist on using the cutoff variable related to the natural subtraction constants such that the resulting poles can be related to dynamically generated states \cite{16,39,40}, we do not find the pole for $\Xi(1690)$ if we switch off the coupling between PB and VB channels.

We have also calculated the branching ratios (in percentage) of our state to the different open channels for decay

$$\sum_i ^{\Gamma_{R \rightarrow i}} \Gamma_{R \rightarrow i},$$

where $\Gamma_{R \rightarrow i}$ represents the partial decay width of the resonance, $R$, to the $i$th channel, and the sum in the denominator, in case of $\Xi(1690)$ is

$$\sum_i \Gamma_{R \rightarrow i} = \Gamma_{\Xi(1690) \rightarrow \bar{K}A} + \Gamma_{\Xi(1690) \rightarrow \bar{K}\Sigma} + \Gamma_{\Xi(1690) \rightarrow n\Xi}$$

The partial decay width is obtained as \cite{38},

$$\Gamma_{R \rightarrow 1+2} = \int_{W_{\text{min}}}^{W_{\text{max}}} \frac{dW}{W^2} \frac{g}{4\pi^2} M_R M_2 | g_{R12} |^2 \tag{32}$$

$$\times \left[ \frac{\Gamma_R}{(M_R - W)^2 + (\Gamma_R/2)^2} \right],$$

where $M_R$, $\Gamma_R$, $M_2$ denote the mass and width of the decaying resonance and the mass of the baryon in the final state, $g$ represents the magnitude of the relative momentum for the final meson-baryon in the center of mass frame, and $g_{R12}$ represents the coupling of the resonance to the decay channel. The coupling of the different channels to the state we associate with $\Xi(1690)$ are given in Table. 1. The variable mass of the resonance, $W$, in Eq. (32) runs from the minimum value, $W_{\text{min}}$, which can be as low as the threshold of the decay channel, to a maximum value, $W_{\text{max}}$, above the resonance mass, which can be as large as $\infty$. However, the precise value of these limits of integration are taken such that

$$\Gamma_{R, \text{tot}} = \sum_i \Gamma_{R \rightarrow i}, \tag{33}$$

where $\Gamma_{R, \text{tot}}$ is the total width of the resonance obtained from the pole position. In the present case of $\Xi(1690)$, it turns out that using $W_{\text{min}} = M_R - 1.6 \Gamma_{R, \text{tot}}$ (if $W_{\text{min}} >$ threshold of the decay channel) and $W_{\text{max}} = M_R + 1.6 \Gamma_{R, \text{tot}}$ in Eq. (32) satisfies the condition in Eq. (33). Note that these values of $W_{\text{min}}$ and $W_{\text{max}}$, coincidentally, happen to be same as those used in Ref. \cite{38} for $f_0(980) \rightarrow \pi \pi$.

The branching ratios of our state to $\pi\Xi$, $\bar{K}A$ and $\bar{K}\Sigma$ are obtained as 17\%, 28.5\% and 54.5\%, respectively. Using these values, we can see that the branching fraction defined by Eq. \cite{39} is 0.52, which is remarkably similar to the experimental value \cite{5}.

The coupling of a resonance to the different channels can be calculated by recalling that the scattering matrix $T$ in Eq. (1) is 0.52, which is remarkably similar to the experimental value \cite{5}.

$$T_{ij} = \frac{g_i g_j}{z - z_R}, \tag{34}$$

where $z_R$ corresponds to the pole position associated to the resonance in the complex plane. Then, the product of the couplings $g_i g_j$ can be identified with the residue, $R_{ij}$, of $T_{ij}$, which can be calculated via an integration of $T_{ij}$ along a closed contour around pole. In this way, $g_i^2 = R_{ii}$, and we can write

$$g_j = \frac{R_{ij}}{\sqrt{R_{ii}}}. \tag{35}$$

It can be seen from the values of these couplings that the

TABLE I: Couplings of different channels to $\Xi(1690)$.

| Channels | Couplings |
|----------|-----------|
| $\pi\Xi$ | $-0.1 - i0.1$ |
| $\eta\Xi$ | $0.9 + i0.2$ |
| $\bar{K}\Sigma$ | $1.5 + i0.2$ |
| $\bar{K}A$ | $-0.3 + i0.1$ |
| $\rho\Xi$ | $0.2 - i0.3$ |
| $\omega\Xi$ | $-0.4 + i0.2$ |
| $\phi\Xi$ | $1.2 + i0.5$ |
| $K^+\Sigma$ | $-1.4 - i0.4$ |
| $K^0\Lambda$ | $0.6 + i0.0$ |

pole given by Eq. (31) couples very weakly to $\pi\Xi$, thus, explaining the difficulty of identifying the state in the data on $\pi\Xi$ mass spectrum \cite{6}. The small coupling of the state to $\bar{K}A$ and the stronger one to $\bar{K}\Sigma$, in spite of the presence of a larger phase space for decay to the former (the masses and the thresholds of different channels are listed in Table. 1) explains why the branching ratio given in Eq. (39) is larger than expected. Thus, all the findings related to $\Xi(1690)$ can be well explained within the coupled channel dynamics of meson-baryon systems which indicate that this state should be interpreted as a dynamically generated state. It should be mentioned that suggestions on the hadronic dynamical origin of $\Xi(1690)$ have also been made in Refs. \cite{10,13,16,20}.

Further, we find it useful to obtain the $\bar{K}A$ and $\bar{K}\Sigma$ invariant mass spectra and compare with the corresponding data available from the processes $\Lambda_c \rightarrow K^+ K^0 A^0$ and
TABLE II: The isospin averaged masses of different particles and the thresholds of different channels. These thresholds are indicated in Figs. 3 and 8 as vertical dashed lines.

| Channels          | Thresholds (MeV) |
|-------------------|------------------|
| (Masses are given in brackets, in MeV) |                   |
| $\pi(137)\Xi(1318)$ | 1455             |
| $\eta(547)\Xi(1318)$ | 1865             |
| $K(496)\Sigma(1193)$ | 1689             |
| $K(496)\Lambda(1116)$ | 1612             |
| $\rho(770)\Xi(1318)$ | 2088             |
| $\omega(782)\Xi(1318)$ | 2100             |
| $\phi(1020)\Xi(1318)$ | 2338             |
| $K^+(892)\Sigma(1193)$ | 2085             |
| $K^+(892)\Lambda(1116)$ | 2008             |

$\Lambda_c \to K^+K^-\Sigma^+$ in Ref. [5]. The mass spectra are calculated using

$$\frac{d\Gamma}{dM_{KB}} \propto P^*_{K+}P^*_{KB}|T|^2, \quad (36)$$

where the $\bar{KB}$ subscript represents the $K^0\Lambda^0$ or $K^-\Sigma^+$ system, $P^*_{K^+}$ is the momentum of $K^+$ in the $\Lambda_c$ rest frame and $P^*_{KB}$ is the center of mass momentum in the $\bar{KB}$ rest frame. Further, to compare with the data outside the peak region, we add to the $\bar{KB}$ $T$-matrix a small background proportional to the phase space. To be explicit, $T$ in Eq. (36) is

$$T = T_{KB} + \bar{B}, \quad (37)$$

where $\bar{B} = 2 \times 10^{-3}$ MeV$^{-1}$ for the $K^0\Lambda$ mass spectrum and $B = 5 \times 10^{-2}$ MeV$^{-1}$ for the $K^-\Sigma^-$ case. A comparison of our results (which is multiplied by an arbitrary constant factor), as well as the background contribution, with the data are shown in Figs. 5 and 6.

A technical remark is here in order. To compare our results with the data, we calculate the momenta in Eq. (36) using the physical masses of the mesons and baryons involved in the process, although the $|T|^2$ has been calculated using average masses (as mentioned earlier). We would like to add here that if we would have used isospin average masses in the phase space to obtain the invariant mass distribution, a peak structure, though closer to the average $K\Sigma$ threshold, would appear in Fig. 6 in spite of having the pole (given by Eq. (31)) below the average $K\Sigma$ threshold. The latter would be a consequence of the finite width of the pole (= 4 MeV). A manifestation of the resonance with the mass below the threshold of a particular channel but with a finite width, allowing the tail of the resonance fall in the physical energy region, has been discussed in Ref. [62].

We have also solved the Bethe-Salpeter equation by calculating the loop function within the dimensional regularization scheme by using natural values of the subtraction constants:

$$a_{\pi\Xi} = -1.05 \quad a_{\eta\Xi} = -2.30 \quad a_{\Lambda\Xi} = -1.90$$
$$a_{K\Lambda} = -1.65 \quad a_{\rho\Xi} = -2.63 \quad a_{\omega\Xi} = -2.64 \quad (38)$$
$$a_{\phi\Xi} = -2.93 \quad a_{K\Sigma} = -2.60 \quad a_{K^*\Lambda} = -2.50.$$

These constants have been obtained by using the condition

$$G[\mu = 630 \text{ MeV}; \sqrt{s} = \sqrt{s_{thr,min}}] = 0, \quad (39)$$

for all the channels, where $\sqrt{s_{thr,min}}$ is the lowest threshold. Such a calculation leads to a pole at $1688 - i1$ MeV, which is similar to Eq. (31). All other results obtained in our work are comparable in a similar way when obtained by using a cutoff or dimensional regularization to calculate the loop integrals. We, thus, would show only the results obtained with a cutoff in the following discussions.

Before proceeding further, it should be mentioned that another pole appears in the spin, isospin 1/2 configuration but deep in the complex plane, around 1530 MeV,
with full width around 200 MeV. A broad structure around this energy region is seen in the $\pi\Xi$ t-matrix (in Fig. 3). However, identifying such broad states in experimental data should be difficult, especially because a narrow $3/2^+$ resonance, $\Xi(1530)$, exists in this energy region. As an example, we show the narrow experimental data should be difficult, especially because a broad structure in the $\pi\Xi$ subsystem and the center of mass momentum are around this energy region is seen in the $\Xi(1530)$ resonance to the s-wave $t$-matrix obtained in the present work. It is possible to notice the presence of a structure around 1690 MeV and a $KA$ cusp around 1612 MeV.

### B. Isospin = 1/2, Spin = 3/2 and Parity = −1

Next, we show the squared amplitudes for the isospin 1/2 and spin 3/2 configurations in Fig. 8. In this case the presence of a resonance can be clearly seen around 2050 MeV, which couples strongly to the $K^*\Sigma$ channel. It is important to mention here that a difficulty arises when investigating the pole corresponding to this state in the complex plane, since the widths of unstable mesons like $\rho$, $K^*$ transform a fixed threshold into a band of energies related to a variable threshold. An appropriate way to tackle this problem would be to calculate the loop functions by including the self-energy of the unstable mesons in the system (for more discussions see, for example, Refs. [43]). Alternatively, an estimation of the effect of the widths of the unstable mesons in the system can be made following the procedure suggested in Ref. [15], which consists of calculating the mass, width and couplings of the state from the squared amplitudes obtained on the real axis. We follow this latter procedure and determine the mass and half width of the spin 3/2 state found in our work as

$$M - i\Gamma/2 = 2046.0 - i8.2 \text{ MeV.} \quad (43)$$

The presence of the pole in the complex plane is confirmed by neglecting the widths of $\rho$ and $K^*$ in the calculations. In such a limit, we do find a pole (as shown in Fig. 9) at

$$M - i\Gamma/2 = 2055 - i2 \text{ MeV,} \quad (44)$$

where the mass value is similar to the one in Eq. (43) obtained from the amplitudes shown in Fig. 8. However,

![Figure 7](image7.png)

**FIG. 7:** The $\pi\Xi$ mass spectrum in the process $\Lambda_c^+ \to \Xi^-\pi^+K^+$ obtained by summing a Breit-Wigner distribution for the $\Xi(1530)$ resonance to the s-wave $t$-matrix obtained in the present work. It is possible to notice the presence of a structure around 1690 MeV and a $KA$ cusp around 1612 MeV.

![Figure 8](image8.png)

**FIG. 8:** Squared amplitudes for total isospin 1/2 and spin 3/2. The vertical dashed lines indicate the thresholds as summarized in Table II.
the width in Eq. (44) is not well determined since \( \rho \) and \( K^* \) have been considered as stable particles for the sake of calculations in the complex plane. In any case, Fig. 8 shows that there exists a pole in the complex plane associated to the peaks seen in squared amplitude in Fig. 8. We can, thus, conclude that a \( \Xi \) baryon with spin-parity \( 3/2^- \) arises at 2046.0–18.2 MeV due to the vector meson-baryon coupled channel dynamics. Once again we come across a \( \Xi \) with a narrow width in spite of the availability of a large phase space to decay. In fact the decay width of this \( \Xi \) is mostly through the decay of \( \rho \) and \( K^* \), and this corresponding peaks in the squared amplitudes tend to get narrower (corresponding to a nearly bound state seen in Fig. 9) if the widths of \( \rho \) and \( K^* \) are considered to be zero.

The question that arises is if we can relate this peak structure with any known state. Two poorly known states around 2 GeV are listed in Ref. [1]: \( \Xi(2030) \) and \( \Xi(2120) \). The former one seems to have a spin \( J \geq 5/2 \) [1]. The existence of the latter one is based on a signal found in the \( \Lambda \Sigma \) mass spectrum [1]. Although the mass of the state in Eq. (43) is far from that of \( \Xi(2120) \), it may be possible to relate the two of them. One reason being the narrow width of \( \Xi(2120) \), which is listed as \( < 20 \) MeV in Ref. [1], which is in good agreement with Eq. (43). Another reason may be that the \( K \Lambda \) channel may not be the most suited channel to investigate the properties of \( \Xi(2120) \), if the latter is related to the state found in our work. As we shall argue now, in such a case, \( \pi \Xi \), \( K \Sigma \) channels should be more suitable to study \( \Xi(2120) \). The couplings of the state in Eq. (43) to different channels are given in Table III. These couplings have been obtained from the amplitudes calculated on the real axis (following Ref. [15]). It can be seen from Table III that the largest coupling of the state are found to \( K \Sigma \) and \( \phi \Xi \) channels. Under the assumption that our state is related to \( \Xi(2120) \), we can say that \( \Xi(2120) \) should mainly decay through \( K \Sigma \) and \( \phi \Xi \) to final states: \( \pi \Xi \), \( K \Sigma \), \( K \Lambda \), as shown in Fig. 10. It can be anticipated that

We also calculate isospin 3/2 amplitudes for spin 1/2 and 3/2 but find no resonance in such configurations, thus, implying absence of any exotic states in our study. A claim of the existence of a narrow, exotic \( \Xi^{--} \) state, with mass \( \sim 1862 \text{ MeV} \), in the \( \pi \Xi \) mass spectrum was reported in Ref. [45]. However, later investigations have failed to confirm the existence of this state (see Ref. [46] for some recent results on this topic).

Finally, we have checked the stability of our results against the variation of the unique parameter of the calculation, which is the cutoff (\( \Lambda = 800 \text{ MeV} \)) used to calculate the loop function (Eq. (27)). We change the cutoff \( \Lambda \) by \( \pm 4\% \) and show, as an example, the variation of the squared amplitudes of the \( K \Sigma \) and \( K^* \Sigma \) channels in Figs. 11 and 12 respectively. The variation in the pole position and half widths of the resonance associated to \( \Xi(1690) \) as well as the \( 3/2^- \) state related to \( \Xi(2120) \) can be summarized as \((1689 \pm 1) + i(2 \pm 1) \text{ MeV}\) and \((2046 \pm 6) + i(8.2 \pm 2.2) \text{ MeV}\), respectively. It can be seen from these summarized results that the states found in our work are reasonably stable.
The possibility of formation of resonances, like $\Xi(1690)$, due to meson-baryon coupled channel dynamics, can affect relevant cross sections. Such a modification of cross sections, in turn, can be useful in understanding the subthreshold $\Xi(1314)$ production observed in Ar+Kcl collisions at 1.76 A GeV (the threshold in nucleon-nucleon collisions is 3.74 GeV) by the HADES Collaboration [24]. The measured $\Xi^-$ abundance is more than one order of magnitude larger than predicted by the statistical model [47] and by the relativistic transport model [48]. An attempt to explain the observed excess of $\Xi^-$ has been presented in Ref. [49], where, with the help of an SU(3) effective Lagrangian model, the authors computed the cross section for the $YY \to N\Xi$, $K\Lambda \to \pi\Xi$ and $\bar{K}N \to \bar{K}\Xi$ reactions. Including these processes in the RVUU transport model the authors obtained the abundance ratio $R_\Xi = \Xi/(\Lambda + \Sigma^0) = 3.38 \times 10^{-3}$, to be compared with the experimental value of $(5.6 \pm 1.2) \times 10^{-3}$. However, the cross sections used for the process $K\Lambda \to \pi\Xi$ in Ref. [49] does not account for the $\Xi(1690)$ resonance formation. The inclusion of such an information drastically enhances the $\bar{K}\Lambda \to \pi\Xi$ cross sections in the lower energy region and changes the line shape of the energy dependence, which should be important. This is shown in Fig. 13, which should be compared with Fig. 2 of Ref. [49]. We also show the cross sections for $\pi\Xi \leftrightarrow \bar{K}\Lambda$, $\pi\Xi \leftrightarrow \bar{K}\Sigma$ processes. The horizontal axis corresponds to the total energy above the respective threshold of each process.

IV. A COMPARISON OF THE RELATIVISTIC AND NONRELATIVISTIC TREATMENT OF THE AMPLITUDES

It is a standard approach to obtain the lowest order amplitudes within a nonrelativistic approximation when studying meson-baryon interactions with the idea of searching for dynamical generation of resonances. In the present case, though, we disregard such an approximation, keeping in mind that the thresholds of the different coupled channels differ up to $\sim 200$ MeV. We find it useful to end this article with a comparison of the different amplitudes obtained within a nonrelativistic approximation with those depicted in Figs. 3 and 8. To be explicit, we wish to compare the squared $t$-matrices shown in Figs. 3 and 8 with those obtained by solving the Bethe-Salpeter equation with the kernels, $V_{\Lambda\Sigma}$, deduced in the nonrelativistic limit, while the loop function $G$ in Eq. (26) continues to be relativistic. Under the nonrelativistic approximation the lowest order amplitudes within a nonrelativistic approximation when studying meson-baryon interactions with the idea of searching for dynamical generation of resonances. In the present case, though, we disregard such an approximation, keeping in mind that the thresholds of the different coupled channels differ up to $\sim 200$ MeV. We find it useful to end this article with a comparison of the different amplitudes obtained within a nonrelativistic approximation with those depicted in Figs. 3 and 8. To be explicit, we wish to compare the squared $t$-matrices shown in Figs. 3 and 8 with those obtained by solving the Bethe-Salpeter equation with the kernels, $V_{\Lambda\Sigma}$, deduced in the nonrelativistic limit, while the loop function $G$ in Eq. (26) continues to be relativistic.
tivisitic approximation (considering energy of the baryon \( E \approx M \), and neglecting the time component of the polarization vector of the vector meson), the contact term, for example, becomes

\[
V_{CT,VB}^{I,s} = i C_{CT,VB}^{I} \frac{g^2 g_2}{2 \sqrt{M_1 M_2}} \vec{\sigma} \cdot \vec{c} \times \vec{c}_1, \quad (45)
\]

where the meaning of \( C_{CT,VB}^{I} \), \( g \) and \( M_1 \), \( M_2 \) is the same as in Eq. (1). Consistently, neglecting the terms of order \( O(|\vec{p}|/\text{mass}) \) (modulus of momentum divided by mass), or bigger, the \( t \)-channel amplitude given by Eq. (16) reduces to

\[
V_{t,VB}^{I} = \frac{-m_{V_x}^2}{4 f_{V_1} f_{V_2}} \left\{ \epsilon_1 \cdot \epsilon_2 \left[ \left( 2 \sqrt{s} - M_1 - M_2 \right) \right. \right.
\]

\[
\left. + (M_1 - M_2) \frac{m_{V_{12}}^2 - m_{V_x}^2}{m_{V_x}^2} C_{i1,VB}^{I} \right. \right.
\]

\[
\left. + \left( \frac{M_1 + M_2}{2M} \right) \left( 2 \sqrt{s} - M_1 - M_2 \right) - \frac{s - u}{2M} \right) C_{i2,VB}^{I} \left\} \right. \right. \}
\]

which can be further simplified by considering that: (1) the term multiplied by \( C_{i2,VB}^{I} \), which is much smaller than the one multiplied by \( C_{i1,VB}^{I} \), is much smaller than the one multiplied by \( C_{i1,VB}^{I} \); (2) the term with \( (m_{V_x}^2 - m_{V_x}^2)/m_{V_x}^2 \) is negligible as compared to the remaining terms; (3) \( \epsilon_1 \cdot \epsilon_2 \). These approximations simplify the \( t \)-channel amplitude to

\[
V_{t,VB}^{I} = \frac{-\vec{c}_1 \cdot \vec{c}_2}{4 f_{V_1} f_{V_2}} \left[ \left( 2 \sqrt{s} - M_1 - M_2 \right) C_{i1,VB}^{I} \right]. \quad (47)
\]

The amplitude in Eq. (47) corresponds to the one used in Refs. \[13-17, 25, 32, 33\]

\[
V_{t,VB}^{I} = -\frac{C_{i1,VB}^{I}}{4 f_{V_1} f_{V_2}} (\omega + \omega^{'}) \vec{c}_1 \cdot \vec{c}_2, \quad (48)
\]

where \( \omega + \omega^{'}, \) represents the sum of the energies of the incoming and outgoing meson, which, in the center of mass, is \( \omega + \omega^{'}, = \sqrt{s} - E_1 - E_2 \approx 2 \sqrt{s} - M_1 - M_2 \) in the nonrelativistic approximation. Analogously, one can easily reduce the lowest order amplitudes for the \( s \)- and \( u \)-channel to

\[
V_{s,VB}^{I,s} = C_{s,VB}^{I} \left( \frac{g^2}{2 \sqrt{M + m}} \right) \vec{c}_2 \cdot \vec{\sigma} \vec{c}_1 \cdot \vec{\sigma}, \quad (49)
\]

\[
V_{u,VB}^{I,s} = C_{u,VB}^{I} \left( \frac{g^2}{2 \sqrt{M - m}} \right) \vec{c}_1 \cdot \vec{\sigma} \vec{c}_2 \cdot \vec{\sigma}, \quad (50)
\]

where \( M \) and \( m \) are SU(3) average masses of the baryon and vector meson and

\[
C_{s,VB}^{I} = \frac{\left( I_{f_1}^{s} I_{11}^{s} - \frac{m}{2M} \left( I_{11}^{s} I_{12}^{s} + I_{22}^{s} I_{11}^{s} \right) + \left( \frac{m}{2M} \right)^2 I_{22}^{s} I_{22}^{s} \right)}{2},
\]

\[
C_{u,VB}^{I} = \frac{\left( I_{f_1}^{u} I_{11}^{u} + \frac{m}{2M} \left( I_{11}^{u} I_{12}^{u} + I_{22}^{u} I_{11}^{u} \right) + \left( \frac{m}{2M} \right)^2 I_{22}^{u} I_{22}^{u} \right)}{2}.
\]

It can be seen from the comparison of the isospin and spin 1/2 amplitudes in Fig. 14 that the presence of the pole and its position corresponding to \( \Xi(1690) \) does not get affected by the nonrelativistic approximation, although the magnitude of the squared amplitudes is different within such an approximation. Yet another difference is the presence of another bump like structure near 2050 MeV in the \( \rho \Xi \) amplitude which does not correspond to a pole in the complex plane but a small variation in the cutoff value can produce a pole corresponding to this peak. We can, thus, summarize that a state with isospin, spin 1/2 and mass near 2050 MeV is not stable and depends on a relativistic or nonrelativistic treatment of the lowest order amplitudes.

We show the comparison of the results obtained within a nonrelativistic approximation considered for the lowest order amplitudes for the meson-baryon system in isospin 1/2 and spin 3/2 configuration in Fig. 15. In this case, we can say that the presence of the pole is not affected by the nonrelativistic approximation but the pole positions differs by about 30 MeV and its coupling to the \( K^* \Lambda \) channel gets too weak to show any signal of the resonance. Like the isospin, spin 1/2 case, the strength of the squared amplitude gets weaker within a nonrelativistic approximation.
Finally, the existence of such cascades in nature might be an interesting information in statistical models trying to understand the ratio of $\Xi^-/\Lambda$ production found in heavy ion collisions [21]. We show the cross sections for the processes $\pi\Xi \leftrightarrow K\Lambda$, $\pi\Xi \leftrightarrow K\Sigma$ which can be useful in studying corresponding in-medium processes.

Next, we list the definitions of the coefficients $V_{u_1}, \ldots V_{u_{12}}$ of Eq. (13):
Here, as in the main part of this manuscript, $M_x$ is the mass of the baryon exchanged, $M_1$ ($M_2$), $E_1$ ($E_2$), represent the mass and energy of the incoming (outgoing) baryon in the process and $K^0$ ($K^0_0$), $\bar{K}_1$ ($\bar{K}_2$) represent the energy and three-momentum of the incoming (outgoing) meson. The products of different isospin coefficients; $I_{i 1}^n$, $I_{f 1}^n$, $I_{i 2}^n$, $I_{f 2}^n$ are given in Tables A13–A16.

**TABLE A12: $C_{PB \rightarrow VB}^{1/2}$ coefficients of the PB $\rightarrow$ VB amplitude (Eq. (19)).**

**TABLE A15: The product $I_{i 3}^n I_{f 3}^n$ appearing in Eqs (A1–A12).**

| $\rho \Xi$ | $\omega \Xi$ | $\phi \Xi$ | $K^* \Sigma$ | $K^* \Lambda$ |
|------------|-------------|-------------|--------------|--------------|
| $\rho \Xi$  | $\frac{(D-F)}{4}$ | $\frac{\sqrt{3}}{2}(D-F)$ | $-(D+3F)$ | $\frac{3}{4}(D+F)$ |
| $\omega \Xi$ | $\frac{(F-D)}{4}$ | $\frac{\sqrt{3}}{2}(D+F)$ | $-(D-3F)$ | $\frac{3}{4}(D+F)$ |
| $\phi \Xi$ | $2F$ | $\frac{1}{2}(D+F)$ | $-(D-3F)$ | $\frac{3}{4}(D+F)$ |
| $K^* \Sigma$ | $\frac{(D-F)}{4}$ | $\frac{1}{2}(D+F)$ | $-(D-3F)$ | $\frac{3}{4}(D+F)$ |
| $K^* \Lambda$ | $\frac{(D-F)}{4}$ | $\frac{1}{2}(D+F)$ | $-(D-3F)$ | $\frac{3}{4}(D+F)$ |
The three-polarization vector of the incoming meson is taken as
\[ \tilde{\epsilon}_{1,\pm} = \mp \frac{1}{\sqrt{2}} (\tilde{\epsilon}_x \pm \tilde{\epsilon}_y), \]  
and the corresponding four vectors are
\[ \epsilon_{1, \pm} = (0, \tilde{\epsilon}_{1, \pm}), \]
\[ \epsilon_{1, 0} = \left( \frac{|\vec{K}_1|}{m_1}, \frac{\epsilon_{1, 0}}{m_1} \right). \]

In this way, we have the Lorenz gauge condition \( K_1 \cdot \epsilon_1 (\lambda) = 0 \), as well as the following conditions, satisfied:
\[ \tilde{\epsilon}_{1, \lambda} \cdot \epsilon_{1, \lambda'} = \delta_{\lambda, \lambda'}, \]
\[ \sum_{\lambda=1}^{3} \epsilon_{1, \mu, \lambda} \epsilon_{1, \nu, \lambda} = -g_{\mu \nu} + \frac{K_{1 \mu} K_{1 \nu}}{m_1^2} \]
\[ \sum_{\lambda=0}^{3} g_{\lambda \lambda} \epsilon_{1, \mu, \lambda} \epsilon_{1, \nu, \lambda} = g_{\mu \nu} \]

The three-polarization vector of the outgoing meson is obtained by rotating the \( \tilde{\epsilon}_{1, \lambda} \), such that \( \tilde{\epsilon}_{2, 0} \) is parallel to \( \vec{K}_2 \), which gives [50]
\[ \epsilon_{2, +} = \frac{1}{\sqrt{2}} \begin{pmatrix} -\cos \theta \\ -i \sin \theta \end{pmatrix}; \epsilon_{2, 0} = \begin{pmatrix} \sin \theta \\ 0 \end{pmatrix}; \epsilon_{2, -} = \frac{1}{\sqrt{2}} \begin{pmatrix} \cos \theta \\ -i \end{pmatrix} \]
and the corresponding four vectors are:
\[ \epsilon_{2, \pm} = (0, \tilde{\epsilon}_{2, \pm}); \]
\[ \epsilon_{2, 0} = \left( \frac{|\vec{K}_2|}{m_2}, \frac{\epsilon_{2, 0}}{m_2} \right). \]

These four vectors satisfy the Lorenz gauge condition as well as the normalization conditions listed by Eqs (B3-B5).
