Abstract

We prove the discrete triality invariance of the \( N = 2 \) NSR superstring moving in a \( D = 2 + 2 \) target space. We find that triality holds also in the Siegel-Berkovits formulation of the selfdual superstring. A supersymmetric generalization of Cayley’s hyperdeterminant, based on a quartic invariant of the \( SL(2|1)^3 \) superalgebra, is presented.
1 Introduction

Cayley’s hyperdeterminant [1], the generalization to cubic $2 \times 2 \times 2$ matrices of the usual determinant of square $2 \times 2$ matrices, was recently recognized [2] to be at the basis of fascinating connections between black hole entropy in string theory and the quantum entanglement of qubits and qutrits in quantum information theory (see [3] and references therein).

The hyperdeterminant was also used in [4] to rewrite the Nambu-Goto Lagrangian for a $D = 4$ target space with signature $(2,2)$ in a way that makes manifest a hitherto hidden discrete symmetry. The eight variables given by the world-sheet derivatives of the string coordinate functions $\partial_\alpha X^\mu$ are rearranged in a $2 \times 2 \times 2$ hypermatrix $X_{AA'A''}$, whose hyperdeterminant square root is shown to coincide with the Nambu-Goto action. The hyperdeterminant being invariant under interchange of the indices $A, A', A''$, the triality invariance of the Nambu-Goto Lagrangian becomes explicit. Moreover the hyperdeterminant encodes in a symmetric way also the $[SL(2,R)]^3$ symmetry of the action, where the $SL(2,R)$ acting on the index $A$ and the $SL(2,R)$ acting on the index $A'$ are the $O(2,2)$ spacetime symmetry, and the $SL(2,R)$ acting on $A''$ is the world-sheet symmetry.

In [5] the Green-Schwarz $\sigma$-model for the $N = 2$ superstring in $D = 2 + 2$ target space was re-expressed in terms of an hyperdeterminant, once the zweibein is eliminated via its (non-algebraic) field equation. The issue of quantum equivalence of the resulting action with the original GS $N = 2$ superstring, or with the NSR $N = 2$ superstring, is still not completely settled.

In this Letter we make manifest a discrete triality invariance of the NSR $N = 2$ superstring moving in a $D = 2 + 2$ target space, without direct recourse to Cayley’s hyperdeterminant, but rearranging the fields in a way suggested by the hyperdeterminant. This triality could well be the origin of the triality observed in [6] between the worldsheet moduli, the complex moduli of the target, and the metric moduli of the target.

Moreover, considering the Siegel-Berkovits action for the selfdual superstring [7, 8, 9], we find that triality holds also in its matter part.

It is natural to ask whether the NSR $N=2$ superstring in $D = 2 + 2$ target space could be expressed in terms of a supersymmetric generalization of the hyperdeterminant. We present such a generalization, based on a quartic invariant of the $SL(2|1)^3$ superalgebra.

2 The $N = 2$ superstring action

The $N = 2$ NSR superstring action [10] in a flat target space of signature $(2,2)$ and in the conformal gauge is given by:

$$S_{N=2} = -\frac{1}{2\pi} \int d^2 \sigma (\partial_\alpha X^\mu \partial^\alpha X^\nu + \partial_\alpha Y^\mu \partial^\alpha Y^\nu - i \overline{\psi_i} \gamma^\alpha \psi_j \partial_\alpha \psi_j^\nu) \eta_{\mu\nu} \quad (2.1)$$

$^1$The $D = 2 + 2$ critical dimension for the $N = 2$ superstring was first found in [11]
where we have used the notations of [12]: $\eta_{\mu\nu} = (1, -1)$ is the two-dimensional Minkowski metric, $\mu = 0, 1, \ i = 1, 2$ and the $\gamma^\alpha$ are the two-dimensional Dirac matrices

$$\gamma^0 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \ \ \ \gamma^1 = \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix} \quad (2.2)$$

The fermions $\psi^\mu_i$ are two-dimensional Majorana fermions, i.e.:

$$\bar{\psi}^\mu_i \equiv (\psi^\mu_i)^\dagger \gamma^0 = (\psi^\mu_i)^T \gamma^0 \quad (2.3)$$

$\gamma^0$ being the charge conjugation matrix (see the Appendix A for conventions). The action (2.1) is invariant under the supersymmetry variations:

$$\delta X = \bar{\tau}_i \psi_i \quad (2.4)$$

$$\delta Y = \epsilon_{ij} \bar{\epsilon}_i \psi_j \quad (2.5)$$

$$\delta \psi_i = -i \gamma^\alpha \partial_\alpha X \epsilon_i + i \epsilon_{ij} \gamma^\alpha \partial_\alpha Y \epsilon_j \quad (2.6)$$

We can rearrange the bosonic and fermionic degrees of freedom (respectively $X^\mu, Y^\mu$ and $\psi^\mu_i$) in the $2 \times 2$ matrices:

$$X_{AA'} \equiv \frac{1}{\sqrt{2}} \begin{pmatrix} -X^0 + X^1 & Y^0 - Y^1 \\ -Y^0 - Y^1 & -X^0 - X^1 \end{pmatrix} \quad (2.7)$$

and

$$\psi_{AA'} \equiv \frac{1}{\sqrt{2}} \begin{pmatrix} -\psi^0_1 + \psi^1_1 & \psi^0_2 - \psi^1_2 \\ -\psi^0_2 - \psi^1_2 & -\psi^0_1 + \psi^1_1 \end{pmatrix} \quad (2.8)$$

Using these notations, the Lagrangian in (2.1) can be recast in the form:

$$\mathcal{L}_{N=2} = (X_{AA'} X_{BB'} - i \bar{\psi}_{AA'} \gamma_{AA'} \partial_{BB'} \psi_{BB'}) \left( \eta^{A'B'} \epsilon^{AB} \epsilon^{A'B'} \right) \quad (2.9)$$

with $X_{AA'} \equiv \partial_{A'} X_{AA'}$. The supersymmetry variations (2.6) become:

$$\delta X_{AA'} = \bar{\tau}_i \rho_i A' B' \psi_{A'B'}$$

$$\delta \psi_{AA'} = -i \partial_{A'} X_{AB'} \rho_i A' \gamma_{A''} \epsilon_i \quad (2.10)$$

where the $2 \times 2$ matrices $\rho_i$ are:

$$\rho_1 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \ \ \ \rho_2 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \quad (2.11)$$
3 Triality invariance

Consider now the world-sheet metric:

\[ G''_{A'B'} \equiv \partial A' X^\mu \partial B' Y^\nu \eta_{\mu \nu} + \partial A'' Y^\mu \partial B'' X^\nu \eta_{\mu \nu} = X_{A'A''} X_{B'B''} \epsilon^{AB} \epsilon^{A'B'} \] (3.1)

In terms of \( G''_{A'B'} \) the bosonic part of the Lagrangian (2.9) is given by:

\[ L_b = \eta^{A'B'} G''_{A'B'} \] (3.2)

As shown by Duff in [4], the Nambu-Goto Lagrangian

\[ L_{NG} = \sqrt{-\det(G''_{A'B'})} \] (3.3)

is invariant under the discrete triality transformations interchanging the three indices of \( X_{A'A''} \). In fact the usual determinant of the world-sheet metric \( G'' \) can be reexpressed as (minus) the Cayley’s hyperdeterminant of the cubic matrix \( X_{A'A''} \), which is explicitly triality invariant [4]:

\[ \text{Det}X \equiv -\frac{1}{2} \epsilon^{A'B'} \epsilon^{CD} \epsilon^{E'D'} \epsilon^{A''D''} \epsilon^{B''C''} X_{A'A''} X_{B'B''} X_{C'C''} X_{D'D''} \] (3.4)

We prove now that also the bosonic Lagrangian \( L_b \) in (3.2) is invariant under triality, up to total divergence terms. To show this, we need the metrics \( G \) and \( G' \) defined by:

\[ G_{AB} \equiv X_{A'A''} X_{B'B''} \epsilon^{A'B'} \epsilon^{A''B''} \] (3.5)
\[ G'_{A'B'} \equiv X_{A'A''} X_{B'B''} \epsilon^{A''B''} \epsilon^{AB} \] (3.6)

With these metrics, we can write the “triality symmetrized” bosonic Lagrangian, explicitly invariant under triality:

\[ L_b = \left( \eta^{AB} G_{AB} + \eta^{A'B'} G'_{A'B'} + \eta^{A''B''} G''_{A''B''} \right) = \left( g^{AA'}, BB' \eta^{A''B''} + B^{AA'}, BB' \epsilon^{A''B''} \right) X_{A'A''} X_{B'B''} \] (3.7)

where

\[ g^{AA'}, BB' = \epsilon^{AB} \epsilon^{A'B'} = g^{BB', AA'} \] (3.8)

plays the role of a 4-dimensional flat metric, and

\[ B^{AA', BB'} = \left( \epsilon^{AB} \eta^{A'B'} + \epsilon^{A'B'} \eta^{AB} \right) = -B^{BB', AA'} \] (3.9)

plays the role of a 4-dimensional constant \( B \)–field.

The triality-invariant Lagrangian (3.7) differs from \( L_b \) in (3.2) by the \( B \)–term: this term is a total divergence, since it is equal to

\[ B^{AA', BB'} \epsilon^{A''B''} \partial_{A''} X_{AA'} \partial_{B''} X_{BB'} = \partial_{A''} \left( B^{AA', BB'} \epsilon^{A''B''} X_{AA'} \partial_{B''} X_{BB'} \right) \] (3.10)
This result can be generalized to the supersymmetric case. The Lagrangian

\[ \mathcal{L}_{N=2} = \left( g^{AA', BB'} \eta^{A'A''} + B^{AA', BB'} \epsilon^{A''B''} \right) \left( X_{AA'A''} X_{BB'B''} - i \bar{\psi}_{AA'} \gamma_{A''} \partial_{B''} \psi_{BB'} \right) \]

is explicitly invariant under (2.10) and triality transformations, and differs from the original \( N = 2 \) superstring Lagrangian in (2.9) only by the \( B \)-terms. Again these terms are a total divergence. This has already been proven for the \( BXX \) term; to show that also the \( B \bar{\psi} \psi \) term is a total divergence we just have to use the antisymmetry of \( B \) and the equality:

\[ \bar{\psi}_{AA'} \gamma_{A''} \partial_{B''} \psi_{BB'} = -\partial_{B''} \bar{\psi}_{BB'} \gamma_{A''} \psi_{AA'} \]

due to \( \psi \) being a \( D = 2 \) Majorana fermion.

### 4 Siegel-Berkovits formulation

As shown by Siegel [7,8] one can describe self-dual super-Yang-Mills in superspace by extending the bosonic coordinates \( X_{AA'} \) to \( (X_{AA'}, \Theta_{Aj}) \) where \( j = 1, \ldots, N \). (We do not include the antichiral coordinates as in [9].) It is convenient to cast the \( (X_{AA'}, \Theta_{Aj}) \) into a supercoordinate \( Y_{Aj} = (X_{AA'}, \Theta_{Aj}) \) with \( J = (A', j) \), which is a vector representation of the supergroup \( OSp(N|2) \). In order to implement the triality we choose the real form \( OSp(2,2|2) \) which has the subgroups \( SO(2,2) \times Sp(2) \sim SL(2,R) \times SL(2,R) \times SL(2,R) \). Therefore, the supercoordinates are labelled by \( (X_{AA1}, \Theta_{AA2A3}) \) where the \( SO(2,2) \) acts on the \( A_2 \) and \( A_3 \) indices, \( Sp(2) \) acts on \( A_1 \) and the supersymmetry generators \( Q_{A1A2A3} \) act as follows

\[ Q_{A1A2A3} X_{BB1} = \epsilon_{A1B1} \Theta_{BA2A3}, \quad Q_{A1A2A3} \Theta_{BB2B3} = \epsilon_{A2B2} \epsilon_{A3B3} X_{BA1}. \]  

Notice that there are effectively four \( SL(2,R) \) groups. Let us denote them by \( SL_0(2,R) \times SL_1(2,R) \times SL_2(2,R) \times SL_3(2,R) \). In addition, we add the \( SL(2,R) \) of the worldsheet and we denote it by \( SL_w(2,R) \). We have denoted by \( A_0, A_1, A_2, A_3, A_w \) the indices for each of them. Thus, for example, the bosonic coordinates \( X_{A_0A_1A_w} \) transform under \( SL_0(2,R) \times SL_1(2,R) \times SL_2(2,R) \times SL_3(2,R) \).

In the formulation of [9], the matter part of the action reads

\[ S_m = \int d^2 z \left( \partial Y_{A} \partial Y^{A'} \right) \]

\[ = \int d^2 z \left( \eta^{A_wB_w} \epsilon^{A_0B_0} \epsilon^{A_1B_1} X_{A_0A_1A_w} X_{B_0B_1B_w} + \eta^{A_wB_w} \epsilon^{A_0B_0} \epsilon^{A_2B_2} \epsilon^{A_3B_3} \Theta_{A_0A_2A_3A_w} \Theta_{B_0B_2B_3B_w} \right) \]

where \( \Theta_{A_0A_2A_3A_w} \equiv \partial_{A_w} \Theta_{A_0A_2A_3} \).

The contraction of indices is performed with the invariant tensors of \( SL_0(2,R) \times SL_1(2,R) \times SL_2(2,R) \times SL_3(2,R) \) (except for the worldsheet indices, contracted...
with the metric $\eta^{A_w B_w}$. The bosonic term is manifestly invariant under the triality exchange of the three groups in $SL_0(2, R) \times SL_1(2, R) \times SL_w(2, R)$: it means that any permutation of the $A_0, A_1, A_w$ indices leaves the action invariant.

It is easy to verify that the action is invariant under the supersymmetry transformations (4.13).

Notice however, that the bosonic term and the fermionic term are separately invariant under the reshuffling of the $SL(2)$ indices. For the action to be invariant under the same triality, we have to identify the groups $SL_i(2, R)$, $i = 1, 2, 3$. Namely, the action is invariant only under the small triality reshuffling and not under the big pentality reshuffling of the fermionic terms. To see this, consider the bosonic coordinates $X_{A_0 A_1 A_w}$. The action is invariant for example under the reshuffling $X_{A_0 A_1 A_w} \rightarrow X_{A_1 A_w A_0}$ as discussed above. However, if we are reshuffling the indices as $X_{A_0 A_1 A_w} \rightarrow X_{A_0 A_2 A_w}$, where we exchange $SL_1(2)$ with $SL_2(2)$, we have to define the new quantities $X_{A_0 A_2 A_w}$ since they are now charged under a new $SL(2)$. So, in order to complete the triality, we have to identify $X_{A_0 A_2 A_w}$ with $X_{A_0 A_1 A_w}$, which means that they transform only under the diagonal subgroup of $SL_1(2) \times SL_2(2)$.

Adding also $X_{A_0 A_3 A_w}$ we obtain an action invariant under $SL_0 \times SL_{diag} \times SL_w$, $SL_{diag}$ being the diagonal subgroup of $SL_1(2) \times SL_2(2) \times SL_3(2)$. In the same way we proceed for the fermions.

We can therefore rewrite the action as

$$S_m = \frac{1}{2} \int d^2 x \left[ \eta^{A_w B_w} \epsilon^{A_0 B_0} (\epsilon^{A_1 B_1} X_{A_0 A_1 A_w} X_{B_0 B_1 B_w} + \epsilon^{A_2 B_2} X_{A_0 A_2 A_w} X_{B_0 B_2 B_w} + \epsilon^{A_3 B_3} X_{A_0 A_3 A_w} X_{B_0 B_3 B_w}) + \eta^{A_w B_w} \epsilon^{A_0 B_0} (\epsilon^{A_2 B_2} \epsilon^{A_3 B_3} \theta_{A_0 A_2 A_3 A_w} \theta_{B_0 B_2 B_3 B_w}) + \epsilon^{A_1 B_1} \epsilon^{A_2 B_2} \theta_{A_0 A_1 A_2 A_w} \theta_{B_0 B_1 B_2 B_w} + \epsilon^{A_1 B_1} \epsilon^{A_3 B_3} \theta_{A_0 A_1 A_3 A_w} \theta_{B_0 B_1 B_3 B_w} \right].$$

The triality under the exchange of $SL_0$, $SL_{diag}$ and $SL_w$ becomes manifest after adding some boundary terms, as we did in the case of the NSR action. This means adding to the metric the $B$ term as in (3.7), replacing the invariant tensors $\eta^{A_w B_w} \epsilon^{A_0 B_0} \epsilon^{A_1 B_1}$ with $\frac{1}{3} (\eta^{A_w B_w} \epsilon^{A_0 B_0} \epsilon^{A_1 B_1} + \eta^{A_0 B_0} \epsilon^{A_1 B_1} \epsilon^{A_w B_w} + \eta^{A_0 B_0} \epsilon^{A_w B_w} \epsilon^{A_1 B_1})$, $\eta^{A_w B_w} \epsilon^{A_0 B_0} \epsilon^{A_2 B_2} \epsilon^{A_3 B_3}$ with $\frac{1}{3} (\eta^{A_w B_w} \epsilon^{A_0 B_0} \epsilon^{A_2 B_2} \epsilon^{A_3 B_3} + \eta^{A_0 B_0} \epsilon^{A_2 B_2} \epsilon^{A_w B_w} + \eta^{A_2 B_2} \epsilon^{A_w B_w} \epsilon^{A_0 B_0}) \times \epsilon^{A_3 B_3}$ and similarly for the terms $\eta^{A_w B_w} \epsilon^{A_0 B_0} \epsilon^{A_1 B_1} \epsilon^{A_3 B_3}$ and $\eta^{A_w B_w} \epsilon^{A_0 B_0} \epsilon^{A_1 B_1} \epsilon^{A_2 B_2}$.

In this way we add only boundary terms.

For the ghost field, the situation is more involved, but since this is a consequence of the specific gauge choice that reduces the Green-Schwarz action to the Siegel-Berkovits action, the possible violation of the triality is only through BRST exact terms which do not affect the physical amplitudes.

There are two important aspects that we have to point out. The first one is that the boundary terms for the fermionic pieces work as in the case of the bosonic terms, and therefore the action is manifestly invariant under the triality that exchanges the three groups $SL_0(2)$, $SL_w(2)$ and $SL_{diag}(2)$. The second aspect, as was noted in [9], is that the choice $\mathcal{N} = 2 + 2$ is mandatory to cancel the BRST anomaly. Here we found that the triality – which is only present in the case of the supergroup $OSp(2, 2|2)$ – implies that cancellation of the anomalies. This is a confirmation of
previous work and an unexpected present from the triality. There is an additional minor point: the fermionic terms display an additional $SL(2,R)$ symmetry which implies a tetrality instead of a triality. We do not have any interpretation, but it might refer to a twist between the R-symmetry and the triality.

The present formulation is suitable for computations of amplitudes and the manifest duality should show up in the computations. This will be explored in a separate work.

5 Super-Hyper-Det based on $SL(2|1)^3$ algebra

Given the results of the previous sections it is natural to try and generalize the hyperdeterminant, invariant under $SL(2)^3$, to a supersymmetric object, invariant under a superalgebra which contains $SL(2)^3$ as a bosonic subalgebra. In fact we can build a quartic (bosonic) supersymmetric object based on the $SL(2|1)^3$ superalgebra which, by setting a suitable set of fields to zero, precisely reproduces the hyperdeterminant of $\Pi$.

The $SL(2|1)^3$ superalgebra is made out of three copies of the following:

$$\begin{align*}
\{Q_A, Q_B\} &= P_{AB} \\
[P_{AB}, Q_C] &= -\epsilon_{C(AQ_B)} \\
[P_{AB}, P_{CD}] &= 2\epsilon_{(A(CP_D)B)}
\end{align*}$$

(5.1)

The indices $A, A', A''$ label the three $SL(2|1)$ factors of the superalgebra. It is possible to construct a $SL(2|1)^3$ representation with 27 fields, 14 of which, $X_{AA'A''}$, $Y_A$, $Y_{A'}$ and $Y_{A''}$, are bosonic while the remaining 13, $\psi_{AA'}$, $\psi_{A'A''}$, $\psi_{A''A}$ and $\eta$ are fermionic. The action of the algebra on the fields is given by:

$$\begin{align*}
Q_A X_{BB'B''} &= \frac{1}{2}\epsilon_{AB} \psi_{B'B''} \\
Q_A^X X_{BB'B''} &= \frac{1}{2}\epsilon_{A'B} \psi_{B'B''} \\
Q_{A''}^X X_{BB'B''} &= \frac{1}{2}\epsilon_{A''B} \psi_{B'B''} \\
Q_A \psi_{BB'} &= \epsilon_{AB} Y_{B'} \\
Q_A^X \psi_{BB'} &= -\epsilon_{A'B} Y_{B'} \\
Q_{A''}^X \psi_{BB'} &= \epsilon_{A''B} Y_{B'} \\
Q_A \psi_{B'B''} &= X_{AB'B''} \\
Q_A^X \psi_{B'B''} &= \epsilon_{AB} Y_{B''} \\
Q_{A''}^X \psi_{B'B''} &= \epsilon_{A'B} Y_{B''} \\
Q_A Y_B &= \frac{1}{2}\epsilon_{AB} \eta \\
Q_A^X Y_B &= \frac{1}{2}\epsilon_{A'B} \eta \\
Q_{A''}^X Y_B &= \frac{1}{2}\epsilon_{A''B} \eta
\end{align*}$$
In the quartic invariant, only the following bilinear building blocks contribute:

\[ X_{(AB)} = X_{A'A''} X_{BB'} \epsilon^{A'B'} \epsilon^{A''B''} \]
\[ A_{(AB)} = \psi_{AA'} \epsilon^{A'B'} \psi_{BB'} \]
\[ B_{(AB)} = \psi_{A'A} \epsilon^{A''B'} \psi_{BB'} \]
\[ W_{(AB)} = Y_A Y_B \]
\[ \omega_A = Y_A \epsilon^{A''B'} \psi_{BB'} \]
\[ \nu_A = Y_A \epsilon^{A'B'} \psi_{AB'} \]
\[ \Delta_A = X_{A'A''} \psi_{BB'} \epsilon^{A'B'} \epsilon^{A''B''} \]
\[ \chi_A = Y_A \eta \]

together with their prime and double prime counterparts; notice that the building blocks with two indices are bosonic and those with one index are fermionic. These blocks can be rearranged in the combinations:

\[ Z_{AB} \equiv 2X_{AB} - A_{AB} - B_{AB} - 2W_{AB} \]
\[ \Phi_A \equiv 2(\Delta_A - \nu_A + \omega_A - \chi_A) \]

which obey very simple supersymmetry relations:

\[ Q_A Z_{BC} = \epsilon_A (B \Phi_C) \]
\[ Q_A \Phi_B = Z_{AB} \]
\[ Q_A \Phi_{A''} Z_{AB} = 0 \]
\[ Q_A \Phi_A = Q_{A'A''} \Phi_A = 0 \]

Then one easily checks that

\[ H = -\frac{1}{48} \left( Z_{AB} Z_{AB} + Z_{A'B'} Z_{A''B''} + Z_{A''B'} Z_{A'B''} + \Phi_A \Phi_B + \Phi_A \Phi_{A'} + \Phi_{A''} \Phi_{A''} \right) \]

is invariant under the action of the superalgebra. The indices are raised/lowered with the use of the \( SL(2) \)-invariant epsilon tensors according to the rule given in \( \text{A.5} \), and the factor \(-\frac{1}{48}\) has been chosen to reproduce the hyperdeterminant once all the fields but \( X_{AA'A''} \) are set to zero.
Note 1: $H$ can be seen as the definition of the super-Cayley determinant of the cubic supermatrix given in Fig. 1:

![Fig. 1: the $3 \times 3 \times 3$ cubic supermatrix](image)

Note 2: $H$ is also equal to the sum of the Berezinians of the three $3 \times 3$ supermatrices

\[
\begin{pmatrix}
Z_{AB} & \frac{1}{\sqrt{2}} \Phi_A \\
\frac{1}{\sqrt{2}} \chi_B & 1
\end{pmatrix}
\begin{pmatrix}
Z_{A'B'} & \frac{1}{\sqrt{2}} \Phi_{A'} \\
\frac{1}{\sqrt{2}} \chi_{B'} & 1
\end{pmatrix}
\begin{pmatrix}
Z_{A''B''} & \frac{1}{\sqrt{2}} \Phi_{A''} \\
\frac{1}{\sqrt{2}} \chi_{B''} & 1
\end{pmatrix}
\]

(5.2)

with $\chi_B \equiv -\Phi^C Z_{BC}^{-1}$ etc.

6 Conclusions and outlook

We have constructed the supersymmetric generalization of the triality invariance first found by Duff in the Nambu-Goto string moving in a flat $D = 2 + 2$ target space. This we achieve by adding boundary terms in the NSR superstring action, and in the Siegel-Berkovits formulation of the selfdual superstring. Moreover we have proposed a supersymmetric generalization of the Cayley hyperdeterminant, based on a quartic invariant of the $SL(2|1)^3$ superalgebra. It may be intriguing to speculate on its possible applications in quantum information or in the description of black holes in string/brane theory.

A $D = 2$ gamma matrices

We use the representation:

\[
\begin{pmatrix}
0 & -i \\
i & 0
\end{pmatrix}
\begin{pmatrix}
0 & i \\
i & 0
\end{pmatrix}
\]

(A.1)
for the two-dimensional $\gamma$-matrices, satisfying the usual relations

\[
\{\gamma^\alpha, \gamma^\beta\} = -\eta^{\alpha\beta} \quad \text{and} \quad \gamma^\alpha \gamma^\beta = -\eta^{\alpha\beta} \mathbf{1} + \epsilon^{\alpha\beta} \gamma_3
\]

where the metric is $\eta = (-, +)$, $\epsilon$ is the usual Levi-Civita symbol and $\gamma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$

The charge conjugation matrix is $C = \gamma^0$, so that all the spinors are real and the following relations hold:

\[
\gamma^0 (\gamma^\alpha)\dagger \gamma^0 = \gamma^\alpha, \quad \gamma^0 (\gamma^\alpha)^t \gamma^0 = -\gamma^\alpha
\]

Finally, for Majorana fermions the currents satisfy:

\[
\xi \zeta = \zeta \xi \quad \text{(A.2)}
\]

\[
\bar{\xi} \gamma_3 \zeta = -\bar{\zeta} \gamma_3 \xi \quad \text{(A.3)}
\]

\[
\bar{\xi} \gamma^\alpha \zeta = -\bar{\zeta} \gamma^\alpha \xi \quad \text{(A.4)}
\]

The $SL(2)$-invariant tensor $\epsilon^{\alpha\beta}$ is used to raise and lower the indices according to:

\[
V_\alpha = \epsilon_{\alpha\beta} V^\beta \\
V^\alpha = -\epsilon^{\alpha\beta} V_\beta \quad \text{(A.5)}
\]

## B Some notes on $OSp(2, 2|2)$

The supergroup is characterized by the following superalgebra generated by the bosonic generators $P_{A'B'}, P_{A'B''}$ and by the fermionic generators $Q_{A'A''}$:

\[
\left\{ Q_{AA'A''}, Q_{BB'B''} \right\} = \frac{1}{2} \epsilon_{A'B'} P_{A'B'} + \frac{1}{2} \epsilon_{AB} P'_{A'B'} \epsilon_{A'B''} - P_{AB} \epsilon_{A'B'} \epsilon_{A'B''},
\]

\[
[P_{AB}, P_{CD}] = 2 \epsilon_{(A(C)P_{D)}B)} \\
[P'_{A'B'}, P'_{C'D'}] = 2 \epsilon_{(A'(C')P'_{D'B'})},
\]

\[
[P^n_{A'B''}, P^n_{C'D''}] = 2 \epsilon_{(A'(C')P^n_{D'B''})},
\]

\[
[P_{AB}, Q_{CC'C''}] = -\epsilon_{C(A)Q_{B)C''}},
\]

\[
[P'_{A'B'}, Q_{CC'C''}] = -\epsilon_{C'(A')Q_{B')C''}},
\]

\[
[P^n_{A'B''}, Q_{CC'C''}] = -\epsilon_{C''(A'')Q_{CC''(B'')}},
\]

They provide the adjoint representation of the superalgebra. Denoting by $T_M$ the supergenerators of $OSp(2, 2|2)$, by $V_M$ the components of the supermultiplet and by $f_{MN}^{\mathcal{R}}$ the super-structure constants, we set

\[
T_M V_N = f_{MN}^{\mathcal{R}} V_{\mathcal{R}}. \quad \text{(B.2)}
\]

and it is obvious to see that it forms a representation. Notice that since the representation is linear, there is no problem to set either $X_{AA'A''}$ as a fermion or as a boson.
