ABSTRACT
The reaction of isatino-3-benzhydrazone (HIBZ), base and organotin(IV) chloride under anhydrous environment a series of biologically active organotin(IV) complexes of the type \([R_nSnCl_{3-n}(IBZ)]\) \([R= Ph, n=3 ; R=Bu, n=3; R=Bu, n=2; R=Me, n=2]\) were synthesized. Characterizations of all synthesized complexes were done on the principle of elemental examination and UV-VIS, FT-IR, \(^1\)H, \(^{13}\)C and \(^{119}\)Sn-NMR spectral techniques. Ligand and its organotin (IV) complexes were tested against bacteria and fungi namely Escherichia coli, Staphylococcus aureus, Aspergillus niger, and Trichoderma reesei, respectively. Some of the organotin (IV) complexes are found to possess better in vitro antibacterial and antifungal screening activity compared to the ligand.

Keywords: Antimicrobial Activities, Organotin (IV) Complexes, NMR Spectroscopy, Isatin Benzoyalhydrazones

INTRODUCTION
During the last several years, organotin(IV) complexes are among the foremost widely used organometallic species of the P-block element.\(^1\)\(^-\)\(^5\) and are widely employed in a range of commercial, agricultural and conjointly shows beneficial use in the pharmacological application as an antimicrobial, antitumoral, biocidal and cytotoxic agent.\(^6\)\(^-\)\(^10\) The presence of heteroatom such as N, O, or S in the ligand plays an imperative role in the geometry and so the complexes showed biological activity.\(^11\)\(^-\)\(^12\) These ligands are competent in coordinating to metal centers, resulting in stable chelating rings. Higher biological activities of organotin(IV) compounds encourage their applications in pharmaceutical.\(^13\)\(^-\)\(^17\) The isatin based mostly benzoyalhydrazones even have a large application to act as potential ligands in various metal-bound complex formation capability to coordinate to metal ion or atom either in the keto or in anionic (iminol) form via loss of ‘amide’ hydrogen.\(^18\)\(^-\)\(^20\) During this study isatinbenzoyalhydrazones ligand and its new organotin(IV) complexes were chosen to be synthesized and focus on spectral characterization and biological assessment to examine the consequence of organic group on the antimicrobial evaluation of organotin(IV) complexes.

EXPERIMENTAL
Material and Methods
Analytical grade reactants and solvents were used. Organotin precursors, liketriphenyltinchloride, tributyltinchloride, dibutyltinchloride, dimetyltinchloride was purchased from Thermo-fisher Scientific (India). Isatin and hydrazone were obtained from Sigma-Aldrich. The solvents (analytical grade) employed in the experimental work are purchased from Rankem, India, and dried before using conventional methods. All manipulations for the syntheses of complexes were executed in anhydrous conditions. Tin was estimated as tin-oxide and nitrogen were estimated as reported in the literature.\(^21\)\(^-\)\(^22\) Thermo scientific flash 2000 was used for elemental analysis. IR spectra [4000–400 cm\(^{-1}\)] were recorded with dry KBr pellets on a SHIMADZU, FT-IR 8400 spectrometer. The data was collected on JEOL FX 300 FTNMR spectrometer in CDCl\(_3\) solution at 300.4 MHz, 75.45 MHz and 111.92 MHz frequencies for

$^1$H, $^{13}$C{$^1$H} and $^{119}$Sn{$^1$H} NMR spectra, respectively. ESI-mass spectra of complexes were obtained on Thermo Finning LCQ Advantage max ion trap spectrometer using methanol solvent. The molecular weight was analyzed by the Beckmann thermometer. Melting points of solids were determined in sealed capillaries, and the decomposition temperatures of sticky solids were determined on a melting point block. Absorption spectra of complexes were recorded using a UV-Vis spectrophotometer from 200 to 800 nm range.

**General Procedure**

**Synthesis of N’-(2-oxo-2, 3-dihydro-1H-indol-3-yl) benzohydrazide (1) (HIBZ)**

**Preparation of Benzohydrazide**

0.34g of ethyl benzoate (0.1M) was added to the solution hydrazine hydrate 99% (0.2M) in ~20 ml of ethanol and refluxed for 2 hrs. The resulting reaction mixture was transferred into cold water and then filtered. The solid product formed was purified with ethanol and dried in a vacuum. m.p.:125°C. Yield: 80%.

**Preparation of N’-(2-oxo-2, 3-dihydro-1H-indol-3-yl) benzohydrazide (1) (HIBZ)**

A mixture of isatin (0.01M) and benzohydrazide, (0.01M) was taken in 20 ml ethanol solvent. This mixture was traces of CH$_3$COOH and refluxed for 3 hours. The reaction mixture was evaporated on a water bath and the residue was decanted onto packed down ice. The obtained solid product was segregated by filtration process and washed with frigid water and then dried in vacuum. M.P:286°C, Yield: 80%.

**Syntheses of Organotin (IV) Complexes**

To the methanolic solution of ligand (HIBZ) N’-(2-oxo-2, 3-dihydro-1H-indol-3-yl) benzohydrazide(1.73 g, 6.55 mmol), 10 ml methanolic solution of NaOH (2mmol) was added dropwise with constant stirring. The light yellow colour sodium salt was formed. This salt solution was refluxed under anhydrous conditions for 01 hours. This methanolic solution of the sodium salt of ligand was added to the anhydrous benzene solution of Bu$_3$SnCl (6.55 mmol, 2.13 g). The colour of the reaction mixture becomes more intense. The ensuing solution was further refluxed for 6 hours under an anhydrous atmosphere. NaCl produced during reaction was filtrated and concentrated in a vacuum, which gave a dark yellow solid. This solid was purified by recrystallization with a mixture of dichloromethane and n-hexane under vacuum as a dark yellow solid. All other Sn (IV) complexes were synthesized similarly.

**Antimicrobial Activity**

*In-vitro* antibacterial activity of all the ligand (HIBZ) and Organotin (IV) complexes were studied against gram-positive *Staphylococcus aureus* and gram-negative *Escherichia coli* bacterial strains by the agar well diffusion method. The samples (10 mg/ml) were prepared in DMSO and further, diluted for calculating MIC value.

**Antifungal Activity**

The antifungal activity of all compounds was examined through the Agar Well Diffusion method. Sterile PBS was used to prepare suspensions of fungal spores and concentrated to 106 cells/ml. All experiments were made in triplicate and means were calculated.

**RESULTS AND DISCUSSION**

Organotin complexes were obtained when the reactions of R$_n$SnCl$_{4-n}$ with the sodium salt of hydrazone ligand (synthesized by reaction of hydrazone and freshly prepared sodium methoxide) in 1:1 molar ratio refluxing in benzene.

All the above reactions were found to be quite facile and quantitatively yielded dark yellow to brown color solids. All these metal complexes obtained as solids are found to be hygroscopic and mostly insoluble in organic solvents except DMF and DMSO. The new complexes were characterized by elemental analysis and IR and $^1$H, $^{13}$C and $^{119}$Sn NMR spectroscopy. Their physical and analytical data are given in Table-1.
IR Spectra
The important IR spectral vibrations and their assignments of organotin complexes are revealed in Table-2. These IR vibrations of all complexes have been compared with the spectrum of free ligands and their ligands derivatives. The \((\text{NH})\) and \((\text{C}=\text{O})\) absorption bands of the amido group which appeared at 3233 \(\text{cm}^{-1}\) and 1624 \(\text{cm}^{-1}\) in the spectrum of free ligand, were not detected in the spectrum of complexes. The \((\text{NH})\) and \((\text{C}=\text{O})\) absorption bands of the amido group which appeared at 3233 \(\text{cm}^{-1}\) and 1624 \(\text{cm}^{-1}\) in the spectrum of free ligand, were not detected in the spectrum of complexes. The emergence of a new band in the IR spectrum of these complexes at 427–477 and 534–549 \(\text{cm}^{-1}\) region, assigned to \(\nu(\text{Sn}-\text{N})\), \(\nu(\text{Sn}-\text{O})\) also supports the coordination of N and O to the tin metal ion respectively.\(^{24,25}\)

The new \(\nu(\text{C}≡\text{N})\) mode observed at 1535 \(\text{cm}^{-1}\) in spectra of hydrazones undergoes little shifts (1625-1632) in the spectrum of the complexes recommend that N atom of the ligand moiety affixed to the indole ring also coordinating to the metal ion in complexes formation. This information was supported by the emergence of a new weak-medium intensity band at 424-479 \(\text{cm}^{-1}\) due to \(\nu(\text{Sn}-\text{N})\) stretching vibrations.\(^{24-25}\)

The above IR spectral data is indicated that all the above-mentioned complexes Sn, the ligand appeared to bind with metal via N and O in a tridentate fashion.

\[ R_n\text{SnCl}_{4-n} \+ \text{HIBZ} \xrightarrow{\text{NaOH/MeOH}} N_2 \text{atmosphere} \xrightarrow{} R_n\text{Sn}([\text{IBZ}])\text{Cl}_{3-n} \]

( where \(n=2,3\) or \(R=\text{Ph, Bu or Me}\) )

Table 1: Analytical and Physical Data of Ligand and its Organotin (IV) Complexes

\(^{1}\)H NMR Spectra
The expected NMR spectral information of ligand and their metal complexes are depicted in Table-3. However, in some cases due to the less solubility of complexes in CDCl\(_3\), the \(^{13}\)CNMR spectra could not be resolved. These data were made by the comparison of the spectrum of free ligand and other related organotin complexes, and corroborate the results observed from the IR spectral studies. The signal appeared at 611.2 ppm due to \(-\text{NH}\) proton in free ligand spectrum, was absent in spectra of all these complexes, suggested that deportation took place during the complexation and ligand attached to the Sn in...
anionic and neutral form. The other protons of ligand moiety like aromatic protons appeared as a multiple in the region δ 6.8–8.0 ppm in the spectrum of complexes and almost the same as ligand. In all the tin complexes, another proton resonance of the organic moiety attached to the Sn metal appeared at the expected position with desirable multiplicities (Table-3).

### Table-3: \(^1\)H NMR Spectral Data of the Ligand and its Corresponding Organotin (IV) Complexes

| Compounds             | Chemical Shift (δ ppm)       |
|-----------------------|------------------------------|
|                        | -NH                         | Aromatic       | Sn-Bu | Sn-Me | Sn-Ph                           |
| HIBZ                   | 14(s,1H)                    | 6.8-8.0 (m, 9H) | -     | -     | -                               |
| Ph\(_3\)Sn(IBZ)        | 14(s,1H)                    | 7.2-7.8 (m, 9H) | -     | -     | 7.2-8.0 (m, 15H)                |
| Bu\(_3\)Sn(IBZ)        | 14(s,1H)                    | 6.5-7.8(m, 9H)  | 0.70-1.46 (m,27H) | -     | -                               |
| Bu\(_2\)Sn(IBZ)Cl      | 14(s,1H)                    | 6.5-8.0(m, 9h)  | 0.94-1.4 (m, 18H) | -     | -                               |
| Me\(_2\)Sn(IBZ)Cl      | 14(s,1H)                    | 6.8-8.2(m, 9H)  | -     | 1.14 (s, 1H) | -                               |

Chemical shift (δ) ppm. Multiplicity is given as: s = singlet, d = doublet, t = triplet, q = quartet, m = complex pattern.

**\(^{13}\)C NMR and \(^{119}\)Sn NMR**

The \(^{13}\)C {\(^1\)H} and \(^{119}\)Sn {\(^1\)H}-NMR spectral data of organotin complexes are revealed in table 4. The chemical shift assessment of C=N and C–O in \(^{13}\)C NMR spectra of complexes that appeared in the region δ 144.50–139.14 and 169.98-163.06 indicate the creation of Sn–N and Sn–O bond, respectively. In \(^{13}\)CNMR spectrum of all the organotin derivatives, all signals for alkyl and aryl groups are observed at the expected regions.

The \(^{119}\)Sn {\(^1\)H}-NMR spectrum of (Ph)\(_3\)Sn(IBZ) complex displayed a sharp single resonance in the region δ 226.24 ppm. \(^{119}\)Sn NMR signals for (Ph)\(_3\)SnCl\(_2\) appear at δ -32 ppm. Based on these observed chemical shift difference, it is assumed that the coordination number of Sn in this complex is six.

**UV Spectra**

The UV–Vis absorption spectra of the above free ligand (HIBZ) and their Sn complexes (1-4) were recorded in methanol solution against ligands blank in the wavelength range 200–800 nm (Fig.-1). The ligand (HIBZ) showed two absorptions at 327 and 248 nm in Fig.-1. The absorption at 248 is owing to the \(\pi–\pi^*\) transitions of the aromatic regions while at 327 nm were assigned due to the \(n–\pi^*\) transition of the C=N or C-O groups. It is supported by literature and related to the \(\pi–\pi^*\) transitions of the aromatic rings.

A small shift in the absorption bands of the complexes compared to the ligand in the spectra is owing to the interaction of ligand to metal transitions. There is considerable shifting in the C=N or C-O due to coordination with tin. Consequently, the shift in the absorption bands reveals coordination between ligand and tin (IV).

![Absorption Spectra of Ligands and their Complexes (against Ligands)](image-url)
Efforts to obtain good quality crystals of complexes were unsuccessful. In absence of crystal structures, it is intricate to comment on the solid-state structure of the complexes. Nevertheless, the above studies do indicate the possibility of the following structures (Fig.-2).

\[
\begin{align*}
R=\text{Ph} & \quad X=\text{Ph} & (1) \\
R=\text{Bu} & \quad X=\text{Bu} & (2) \\
R=\text{Bu} & \quad X=\text{Cl} & (3) \\
R=\text{Me} & \quad X=\text{Cl} & (4)
\end{align*}
\]

### Antimicrobial Activity of Organotin (IV) Complexes

Antimicrobial activity of the new ligand and their organotin complexes were investigated against two bacteria and two fungus, *S. aureus* (G⁺) & *E. coli* (G⁻) and fungal *T. reesei* (G⁺) and *A.niger* (G⁻), respectively. The results of the Antimicrobial activity are revealed in Table-5 and Figs.-3 and 4.

The ligand HIBZ did not show any anti-bacterial as well as antifungal activity against the tested microorganisms like *S. aureus* (G⁺) and *A.niger* (G⁻) while it shows activity against *E. coli* (G⁻) and *T. reesei* (G⁺). Higher anti-microbial activity of ligand complexes is because of the consequence of metal ions on the normal cell processes. An apparent mode for the activity raise may be measured in the light of Tweedy’s-Chelation theory. Chelation significantly reduced the polarity of metal ions owing to the fractional allocation of its +ve charge with donor groups and the π-electron delocalization over the complete chelate ring. Such chelation could increase the lipophilic nature of the central metal atom, which favors its permeation through the lipid layer of the cell membrane.

As shown in Table-5 all organotin complexes were observed significant activity against all the screened microorganisms and fungi but complexes Bu$_2$Sn(IBZ)Cl and Bu$_3$Sn(IBZ) do not show any bacterial and fungal growth against tested microorganisms and fungi, *S. aureus* and *A. Niger*, respectively.

### Table 5: Antibacterial Activity Data for Ligands and their Anionic Complexes after 24 hours.

| Compound         | Concentration (mg/Disc) | Average Value of Bacteriostatic Diameter (mm)* | Average Value of Fungal Static Diameter (mm)* |
|------------------|-------------------------|-----------------------------------------------|---------------------------------------------|
|                  |                         | *S. aureus* | *E. coli* | *T. reesei* | *A.niger* |
| Standard         | 1                       | 22          | 21        | 20          | 20        |
| HIBZ             | 1                       | 0           | 12        | 15          | -         |
| Ph$_3$Sn(IBZ)    | 1                       | 15          | 19        | 21          | 22        |
| Bu$_3$Sn(IBZ)    | 1                       | 27          | 25        | 26          | -         |
| Bu$_2$Sn(IBZ)Cl  | 1                       | 0           | 20        | 22          | 22        |
| Me$_2$Sn(IBZ)Cl  | 1                       | 35          | 24        | 25          | 23        |

Agar well diffusion method (in vitro) = 1.0mg mL$^{-1}$; Reference drug = Ciprofloxacin (for bacteria) Inhibition zone - 22mm, Ketokenazole (for fungi) – Inhibition zone-20mm. * Standard.
In general complexes Me₂Sn(IBZ)Cl showed high activity against all G− or G+ bacteria and fungi. This effect indicates that the methylorganotin complex is highly active compared to the other organotin complexes. Complexes Me₂Sn(IBZ)Cl and Bu₂Sn(IBZ)Cl were shown the most potent activity than the standard for both the bacteria and fungi as shown in the table. The result shows that all organotin complexes showed enhanced antimicrobial activity as compared to the parent ligands.

**CONCLUSION**

The four new organotin complexes with hydrazine ligand were synthesized and characterized through elemental analyses, MS, IR and NMR spectral data. Monofunctional tridentate behaviour of hydrazine ligand was suggested based on spectral data. ¹H, ¹³C and ¹¹⁹Sn-NMR values support the hexa coordinated to tin atom. The metal complexes appeared more potent activity than the corresponding ligand because of antimicrobial activities, and the activity affected the group attached to the Sn atom.

**ACKNOWLEDGEMENT**

The authors are thankful to the Head, Department of Chemistry, for providing the necessary research facilities. This study received financial assistance from the University of Rajasthan, Jaipur during the research work. We are also thankful to USIC (University Science Instrumentation Centre) and MNIT Jaipur for providing analytical and spectral data.
