The Involvement of Ca$^{2+}$ Signal Pathways in Distal Colonic Myocytes in a Rat Model of Dextran Sulfate Sodium-induced Colitis

Yan Wang, Jun-Xia Li, Guang-Ju Ji, Kui Zhai, Hua-Hong Wang, Xin-Guang Liu

Abstract

Background: Disrupted Ca$^{2+}$ homeostasis contributes to the development of colonic dysmotility in ulcerative colitis (UC), but the underlying mechanisms are unknown. This study aimed to examine the alteration of colonic smooth muscle (SM) Ca$^{2+}$ signaling and Ca$^{2+}$ handling proteins in a rat model of dextran sulfate sodium (DSS)-induced UC.

Methods: Male Sprague-Dawley rats were randomly divided into control (n = 18) and DSS (n = 17) groups. Acute colitis was induced by 5% DSS in the drinking water for 7 days. Contractility of colonic SM strips (controls, n = 8 and DSS, n = 7) was measured in an organ bath. Cytosolic resting Ca$^{2+}$ levels (n = 3 in each group) and Ca$^{2+}$ transients (n = 3 in each group) were measured in single colonic SM cells. Ca$^{2+}$ handling protein expression was determined by Western blotting (n = 4 in each group). Differences between control and DSS groups were analyzed by a two-sample independent t-test.

Results: Average tension and amplitude of spontaneous contractions of colonic muscle strips were significantly enhanced in DSS-treated rats compared with controls (1.25 ± 0.08 g vs. 0.96 ± 0.05 g, P = 0.007; and 2.67 ± 0.62 g vs. 0.52 ± 0.10 g, P = 0.013). Average tensions of carbachol-evoked contractions were much weaker in the DSS group (1.08 ± 0.10 g vs. 1.80 ± 0.19 g, P = 0.006). Spontaneous Ca$^{2+}$ transients were observed in more SM cells from DSS-treated rats (15/30 cells) than from controls (5/36 cells). Peak caffeine-induced intracellular Ca$^{2+}$ release was lower in SM cells of DSS-treated rats than controls (0.413 ± 0.046 vs. 0.548 ± 0.041, P = 0.033). Finally, several Ca$^{2+}$ handling proteins in colonic SM were altered by DSS treatment, including sarcoplasmic reticulum calcium-transporting ATPase 2a downregulation and phospholamban and inositol 1,4,5-trisphosphate receptor 1 upregulation.

Conclusions: Impaired intracellular Ca$^{2+}$ signaling of colonic SM, caused by alteration of Ca$^{2+}$ handling proteins, contribute to colonic dysmotility in DSS-induced UC.

Key words: Calcium; Dextran Sulfate Sodium; Inositol 1,4,5-trisphosphate Receptor; Large-conductance Calcium-activated Potassium Channels; Phospholamban Protein; Sarcoplasmic Reticulum Calcium-transporting ATPase Calcium ATPase; Ulcerative Colitis

Introduction

Ulcerative colitis (UC) involves chronic, relapsing inflammation of the gastrointestinal tract. Previous studies showed that, in UC, colon motility was abnormal, with increased propulsive activity and decreased segmenting contractions.[1-2] These motor abnormalities can persist even in patients with quiescent UC.[3] However, the underlying mechanisms of the abnormal motility are unclear. Changes in the enteric nervous system may contribute to the motility.[4-6] However, the altered contractility of smooth muscle (SM) also plays a potentially important role.

Increased cytosolic Ca$^{2+}$ is crucial to SM contraction, which relies on Ca$^{2+}$ influx from extracellular stores and Ca$^{2+}$ release from intracellular stores during action potentials. It was reported by some that reduced Ca$^{2+}$ influx...
contributed to dysmotility in colitis,[7,8] and by others that disrupted calcium release was the major cause of colonic dysmotility.[9-12] The alteration of Ca\(^{2+}\) pathways in colonic SM during colitis, therefore, remain unclear.

Inositol 1,4,5-trisphosphate receptor (IP3R) and ryanodine receptor (RyR) are Ca\(^{2+}\) release channels while sarcoplasmic reticulum Ca\(^{2+}\) -ATPase (SERCA) is a Ca\(^{2+}\) pump residing on the sarcoplasmic reticulum (SR). Alteration in these channels can impair Ca\(^{2+}\) homeostasis and result in abnormal SM contractility.

The aim of this study was to determine, in a UC model: (1) whether intracellular Ca\(^{2+}\) stores were changed during inflammation, and if so, how this alteration influenced colonic motility; and (2) the underlying molecular mechanisms of impaired intracellular Ca\(^{2+}\) homeostasis.

**Methods**

**Animals**

Male Sprague-Dawley rats (aged 7 weeks and weighing 190–210 g) were purchased from Vital River Laboratories (Beijing, China) and housed in the animal facility of Peking University First Hospital, in accordance with approved ethical guidelines. Animals were exposed to light: dark cycles (12 h: 12 h) with a controlled environmental temperature (22°C) and were acclimatized for 3 days before entering the study.

**Animal grouping and induction of colitis**

Using a random number table, 35 normal rats were divided into control (n = 18) and dextran sulfate sodium (DSS) (n = 17) groups. Induction of colitis was performed as previously described with minor alteration.[13] Rats of the DSS group were administered 5% DSS (MW 36,000–50,000; MP Biomedicals, LLC, OH, USA) in the drinking water for 7 days. Control, or healthy, rats drank only the same tap water. On day 8, the distal colons were removed from rats anesthetized with 5% chloral hydrate (Sigma-Aldrich, St. Louis, MO, USA). After removing feces, colons were fully cleaned with ice-cold extracellular solution (140 mmol/L NaCl, 2 mmol/L CaCl\(_2\), 10 mmol/L HEPES, 3 mmol/L glucose, pH 7.4). Colon segments at 5 cm above the anus were harvested and used for further analysis. Using a random number table, 8 control and 7 DSS-treated rats were selected and contractility of the muscle strips was measured. In addition, 3 rats were selected from each group to measure Ca\(^{2+}\) transients and another 5 rats to measure cytosolic Ca\(^{2+}\). The remaining 4 rats in each group were used to harvest tissues for Western blotting. The experiment was performed at the National Laboratory of Biomacromolecules, Chinese Academy of Sciences, Beijing, China.

**Histological staining**

Distal colon segments were fixed in paraformaldehyde (Sigma-Aldrich) for 24 h and were then embedded in paraffin and sectioned (5 μm) onto glass slides. Hematoxylin-eosin staining was performed using standard protocols. Images were acquired on a Leica SCN400 Scanner microscope (Leica, Mannheim, Germany).

**Contractile measurement of rat colonic muscle strips in vitro**

Contractile measurements were performed as previously described with minor alteration.[14] To measure isometric tension contractions, approximately 0.5 cm freshly prepared muscle strips with mucosa were suspended in the circular direction in a 10-ml organ bath, coupled with a model BL-420F acquisition system (Chengdu TME Technology Co., Ltd., Sichuan, China), and containing oxygenated Krebs solution (119 mmol/L NaCl, 2.5 mmol/L CaCl\(_2\), 4.7 mmol/L KCl, 1.17 mmol/L MgSO\(_4\), 1.18 mmol/L KH\(_2\)PO\(_4\), 25 mmol/L NaHCO\(_3\), 11 mmol/L glucose) at 37°C. The tissues were allowed to equilibrate for 1 h, with the bath fluid changed every 15 min, at a resting tension of 1 g. After equilibration, 1 μmol/L carbachol (Cch) (Sigma-Aldrich) was used to stimulate contraction of the muscle strips. After washing out the Cch, 20 mmol/L KCl was applied to enhance muscle strip contraction. The mean amplitude, frequency and average tension of spontaneous, Cch- and KCl-enhanced contractions were measured from 5 min before until 5 min after application of each treatment.

**Isolation of smooth muscle cells**

Single SM cells were prepared enzymatically as previously described with minor modifications.[15] The mucosa and serosa of distal colon segments were removed under a microscope. The SM was then minced and incubated in a Ca\(^{2+}\)-free enzyme extracellular solution containing 2 mg/ml papain, 1 mg/ml dithiothreitol, and 1 mg/ml bovine serum albumin (BSA) (all from Sigma-Aldrich) for 20 min at 37°C. The solution was then decanted and the cell suspension rinsed three times and placed in a low Ca\(^{2+}\) (0.1 mmol/L) extracellular solution containing 1 mg/ml collagenase H (Roche Diagnostics, Mannheim, Germany), 1 mg/ml dithiothreitol and 1 mg/ml BSA for an additional 15 min at 37°C. Next, collagenase-free low Ca\(^{2+}\) extracellular solution was used to wash the suspended cells to remove all collagenase and single cells were released by gentle agitation. Cells were maintained in the low Ca\(^{2+}\) extracellular solution supplemented with 1 mg/ml BSA at 4°C.

**Measurement of Ca\(^{2+}\) fluorescence**

Freshly isolated colonic SM cells on glass coverslips were incubated with 5 μmol/L Fluo-4 AM (Molecular Probes, Eugene, OR, USA) for 20 min at 37°C and then perfused for 20 min at room temperature with normal extracellular solution. The 40-μm immersion objective of an inverted microscope (Leica) connected to a software-controlled (Las AF, Leica) cooled charge-coupled camera (Leica SP5 confocal microscope) was used to capture images. X-Y images were obtained every 573 ms for 2 min. To capture spontaneous transients, SM cells were first perfused with normal extracellular solution for about 20 min and then 10 mmol/L caffeine (Sigma-Aldrich) was directly applied to evoke Ca\(^{2+}\) transients and cell contraction. Custom software written in MATLAB (The Mathworks Inc., Natick, MA, USA) was used to calculate kinetic data, including peak F/F\(_0\), starting time, rising time, and half-time of decay.
final offset using nonlinear least squares fitting routine. Leica Las AF software (Leica, Mannheim, Germany) was used to analyze X-Y images, and fluorescence profiles were constructed and transferred to Microsoft Excel (Microsoft Corp., Redmond, WA, USA). The average fluorescence value of the continuous 20 images without Ca\(^{2+}\) transient activity was calculated as F0. The amplitude and frequency of Ca\(^{2+}\) transients were calculated before and after caffeine application. Microsoft Excel software was used to determine kinetic parameters of the Ca\(^{2+}\) signals.

**Cytosolic Ca\(^{2+}\) measurements**

Freshly isolated cells were kept in extracellular solution and incubated with 2 \(\mu\)mol/L Fura 2-AM (molecular probes) for 20 min. Then SM cells were placed in chambers mounted on the stage of an inverted microscope (Olympus, Tokyo, Japan). The excitation wavelengths were switched between 340 and 380 nm and fluorescence emission was measured at 510 nm. Cytosolic Ca\(^{2+}\) concentrations were calculated from fluorescence ratios as previously described.\[^{[16]}\]

**Western blotting analysis**

Western blotting analysis was performed as described previously\[^{[17]}\] with minor modifications. SM samples were homogenized in RIPA buffer (Cell Signaling Technology, Inc., Danvers, MA, USA) to extract protein. Samples were heated at 90°C for 5 min and centrifuged at 5000 \(\times g\) for 5 min. The supernatants were resolved on 10% (for large-conductance calcium-activated potassium channel [BKCa], SERCA2a and nuclear factor-kappa B [NF-\(\kappa\)B]) or 8% (for IP3R1) SDS-polyacrylamide gels and 4–12% Bis-Tris Gels (Invitrogen, NY, CA, USA) (for phospholamban [PLB]). The resolved protein bands were transferred to PVDF membranes (Millipore, Bedford, MA, USA) at 300 mA for 1 h (BKCa, NF-\(\kappa\)B), 300 mA for 1.5 h (SERCA2a), 400 mA for 1.5 h (IP3R1), or 400 mA for 1 h (PLB). The membranes were blocked with Tris-buffered saline-Tween 20 containing 5% nonfat dry milk (Sigma-Aldrich) at room temperature for 1 h and then incubated at 4°C overnight with anti-SERCA IgG (1:1000, ab2801, Abcam, Cambridge, UK), anti-BKCa IgG (1:1000, ab3587, Abcam), anti-NF-\(\kappa\)B IgG (1:2000, 8242, Cell Signaling Technology, Inc.), anti-IP3R1 IgG (1:1000, ab5804, Abcam) or anti-PLB IgG (1:1000, ab2865, Abcam). The membranes were washed and then incubated with the appropriate secondary antibodies at room temperature. After washing, labeled bands were detected using enhanced chemiluminescence solutions 1 and 2 (1:1) (Millipore).

**Statistical analyses**

Data are expressed as mean ± standard error (SE). Statistical differences between means were determined with SPSS version 16.0 (SPSS, Chicago, IL, USA). Differences between control and DSS groups were analyzed using two-sample independent \(t\)-test and comparison within the group before and after infusion of various stimulations were compared by paired \(t\)-test. Bonferroni correction was performed in multiple comparisons. \(N\) represents the number of cells and \(n\) represents the number of rats. \(P < 0.05\) was considered statistically significant.

---

**RESULTS**

**Morphology and histopathology**

Rats drinking DSS solution for 7 days had colitis with diarrhea and bloody stools. The lengths of the large intestines in DSS treated rats (\(n = 7\)) were much shorter than in controls (\(n = 8\)) (14.4 ± 0.8 cm vs. 18.6 ± 0.3 cm, \(t = 5.174, P < 0.001\)) [Figure 1a and 1b]. In contrast, no statistical differences in

**Figure 1:** Changes in colonic length, body weight and histology. (a and b) The length of the large intestines from control and DSS treated rats. (c) Changes in body weight shown as percentage of weight on d 0. (d-g) Representative H and E stained sections showing histology of colons from control (d-e) and DSS treated rats (f-g). Data are mean ± SE of \(n\) (controls, \(n = 8\) and DSS, \(n = 7\)) independent colonic strips. *\(P < 0.05\); NS: Not significantly different. DSS: Dextran sulfate sodium; SE: Standard error.
weight gain were observed between these two groups (28 ± 2% vs. 29 ± 1%, t = 0.432, P = 0.673) [Figure 1c]. Histopathology indicated that several features of colonic inflammation such as superficial focal ulceration, crypt abscess, areas of crypt destruction and infiltration of inflammatory cells in the submucosa were observed in DSS treated but not in control rats [Figure 1d-1g]. NF-κB, a transcription factor regulating expression of various inflammatory cytokines, was upregulated within the SM layer in DSS treated rats (1.56 ± 0.17 vs. 0.81 ± 0.20, t = 2.844, P = 0.029, n = 4) [Supplementary Figure 1].

Spontaneous and stimului-mediated contractions of colonic smooth muscle strips from control and dextran sulfate sodium treated rats

Average tensions and amplitudes of the spontaneous phasic contractions of SM strips from DSS treated rats (n = 7) were significantly increased compared with those from controls (n = 8) (1.25 ± 0.08 g vs. 0.96 ± 0.05 g, t = 3.198, P = 0.007 and 2.67 ± 0.62 g vs. 0.52 ± 0.10 g, t = 3.676, P = 0.013, respectively) [Figure 2a, 2d and 2g-2h]. The frequencies of spontaneous phasic contractions of SM strips from DSS treated rats were similar to controls (12.14 ± 0.82 cycles per minute [cpm] vs. 13.15 ± 1.17 cpm, t = 0.685, P = 0.523) [Figure 2i].

The average tension (1.59 ± 0.14 g vs. 1.48 ± 0.12 g, for DSS treated and control rats, respectively, t = 0.656, P = 0.523) and frequency (22.20 ± 2.07 cpm vs. 18.80 ± 1.96 cpm, for DSS treated and control rats, respectively, t = 1.193, P = 0.254) of KCl (20 mmol/L)-induced contractions of muscle strips between the control and colitis were not markedly different [Figure 2c, 2f, 2g and 2i]. The amplitude of KCl (20 mmol/L)-induced contractions of muscle strips of colitic rats was higher compared to control rats (2.12 ± 0.40 g vs. 0.94 ± 0.31 g, t = 2.359, P = 0.035) [Figure 2h].

In control rats, the Cch (1 μmol/L) induced contractions of SM strips had an average tension that was increased about 2-fold above baseline (from 0.96 ± 0.05 g to 1.80 ± 0.19 g, t = 5.424, P = 0.001) [Figure 2b and 2j] and an amplitude of phasic contraction increased over 7-fold (from 0.52 ± 0.10 g to 3.62 ± 0.60 g, t = 5.005, P = 0.002) [Figure 2k]. However, in SM strips from the DSS group, Cch did not significantly increase either average tension or amplitude of phasic contractions [Figure 2e and 2j-2k]. Thus, compared to control groups, the average tension of Cch-evoked contractions in DSS group were much weaker (1.08 ± 0.10 g vs. 1.80 ± 0.19 g, t = 3.253, P = 0.006). In both DSS and control rats, there was no statistically significant effect of Cch on frequency of SM contractions (17.03 ± 3.11 cpm vs. 19.35 ± 2.10 cpm, t = 0.632, P = 0.538) [Figure 2l].

Ca²⁺ transients were significantly altered in colonic smooth muscle of dextran sulfate sodium treated rats

In Fluo-4 AM-loaded colonic SM cells from both control and DSS treated rats (n = 3) spontaneous Ca²⁺ transients were observed but these were more likely to occur in cells

![Figure 2](image-url)
from the DSS treated rats (50% vs. 14%, $N = 30$ in DSS group and $N = 36$ in control group) [Figure 3a and 3b]. The frequency (0.021 ± 0.004 Hz vs. 0.027 ± 0.005 Hz, $t = 0.752, P = 0.462$) and amplitude ($F/F_0$) (0.189 ± 0.025 vs. 0.211 ± 0.025, $t = 0.481, P = 0.636$) of Ca$^{2+}$ transients of SM cells from DSS treated rats were similar to that of control rats [Figure 3c and 3d].

The amplitudes of caffeine-induced Ca$^{2+}$ transients from DSS treated rats were significantly lower than controls (0.413 ± 0.046 vs. 0.548 ± 0.041, $N = 24$ in DSS group and $N = 34$ in control group, $t = 2.184, P = 0.033$) [Figure 3e and 3f]. In myocytes from DSS treated rats, time to peak (0.481 ± 0.054 s vs. 0.749 ± 0.083 s, $t = 2.459, P = 0.017$) and time of decay (2.773 ± 0.294 s).  

Figure 3: Impairment of spontaneous and caffeine induced Ca$^{2+}$ transients. (a-d) Typical fluorescence profiles and summary data showing the number of cells, $F/F_0$ and frequency of spontaneous Ca$^{2+}$ transients (controls, $N = 36$; DSS, $N = 30$). (e-h) Representative fluorescence profiles and summary data showing $\Delta F/F_0$, time to peak and time of decay of caffeine-induced Ca$^{2+}$ transients (controls, $N = 34$; DSS, $N = 24$). (i) Summary data showing cytosolic Ca$^{2+}$ levels in SM cells (controls, $N = 50$; DSS, $N = 58$). Data are mean ± SE of $N$ cells isolated from $n$ rats ($n = 3$). *$P < 0.05$; NS: Not significantly different. DSS: Dextran sulfate sodium; SE: Standard error.
vs. 5.399 ± 0.929 s, t = 2.311, P = 0.010) were significantly shorter than those from controls [Figure 3g and 3h].

The cytosolic Ca²⁺ levels measured in Fura-2 AM-loaded colonic SM cells from DSS treated rats were similar to those in controls (1.768 ± 0.023 vs. 1.727 ± 0.017, N = 58 in DSS group and N = 50 in control group, t = 1.386, P = 0.169) [Figure 3i].

Altered expression of Ca²⁺ handling proteins
Because SERCA2a, PLB, IP3R1, and BKCa are Ca²⁺ handling proteins in SM cells, their expression in colonic SM from control and DSS treated rats (n = 4) were analyzed by Western blotting. As shown in Figure 4, SERCA2a expression within the SM layer was significantly lower in DSS treated rats than in controls (0.42 ± 0.05 vs. 0.66 ± 0.06, t = 3.274, P = 0.017) [Figure 4b]. Expression of PLB (1.05 ± 0.05 vs. 0.56 ± 0.14, t = 3.187, P = 0.019) [Figure 4c] and IP3R1 (1.56 ± 0.16 vs. 0.63 ± 0.04, t = 5.689, P = 0.001) [Figure 4d] was significantly higher in DSS treated rats than in controls. However, BKCa expression was similar in both groups (0.97 ± 0.04 vs. 0.98 ± 0.04, t = 0.310, P = 0.767) [Figure 4e].

DISCUSSION
In this study, we used DSS-treated rats to assess the impact of Ca²⁺ signaling alterations on the disrupted contractility of colonic SM and further investigated the underlying mechanisms of disrupted Ca²⁺ signaling pathways during UC. DSS-treated rats provide a reliable animal model of the disease, exhibiting some of the clinical and histopathological characteristics of UC.[18-21] In addition, some therapeutic agents for UC were effective in DSS-induced colitis.[19]

All rats treated with DSS in our study had diarrhea and hematochezia. Their colon lengths were shorter than those of control rats and they showed mucosal ulcerations and inflammatory cell infiltrations.

Decreased segmenting colonic contractions and increased propagating contractions in patients with UC[2] were previously demonstrated, but the underlying mechanisms of this process have been controversial. Our results showed that compared with control rats, the amplitude and average tension of spontaneous contractions of the colonic SM from DSS-treated rats were much higher while Cch-evoked contractions were significantly lower. However, contractile responses to KCl were similar in the two groups. Potassium initiates contraction via membrane depolarization and activation of calcium influx through voltage-sensitive channels. Because the response to potassium in the SM strips from DSS-treated rats were similar to that in the control, it is reasonable to speculate that this pathway did not contribute to the alteration of contractility in the...
In our study, we [7,8,24] found that in SM from DSS compared with control animals, SERCA2a, the major isoforms expressed in colonic SM cells. Meanwhile, expression levels of IP3R1 were clearly increased in rats with colitis, which might explain the higher incidence, compared with in control animals, of Ca^2+ transients in inflamed colonic SM cells and the shortened colon length in DSS-treated rats. These preliminary findings agreed with reports by Al-Jarallah et al.[14] and Qureshi et al.[11]

BKCa can be activated directly by Ca^2+ release from the SR in SM cells of the gastrointestinal tract, leading to membrane hyperpolarization and decreased Ca^2+ entry through voltage-dependent Ca^2+ channels and ultimately resulting in muscle relaxation.[127] In our study, we demonstrated that BKCa expression was similar in DSS and control groups, further eliminating this pathway as a contributor in the decreased SM contractility in UC. That is, decreased extracellular Ca^2+ entry is not a likely reason for the dysmotility. However, further investigation will be needed to assess whether BKCa function is altered in UC.

In summary, our study showed that spontaneous contractility increased significantly and Cch-evoked contraction decreased remarkably in DSS-induced UC. Abnormalities in intracellular Ca^2+ stores, including increased Ca^2+ transients and impaired refilling of intracellular stores, accounted for the observed dysmotility. The underlying mechanism involved increased IP3R1 expression and decreased expression and function of SERCA2a.

Supplementary Figure 1: Upregulated NF-κB expression in colonic SM from DSS treated rats, compared with controls. (a) Representative Western blots for NF-κB. (b) Summary data showing NF-κB expression. Values are mean ± SE of n rats (n = 4 per group). At least 3 separate experiments were performed and showed similar results. *P < 0.05 versus vehicle. SE: Standard error; DSS: Dextran sulfate sodium; SM: Smooth muscle; NF-κB: Nuclear factor-kappa B.
