Uniformly bounded orthonormal polynomials on the sphere

Jordi Marzo and Joaquim Ortega-Cerdà

Abstract

Given any $\varepsilon > 0$, we construct an orthonormal system of $n_k$ uniformly bounded polynomials of degree at most $k$ on the unit sphere in $\mathbb{R}^{m+1}$ where $n_k$ is bigger than $1 - \varepsilon$ times the dimension of the space of polynomials of degree at most $k$. Similarly, we construct an orthonormal system of sections of powers $A^k$ of a positive holomorphic line bundle on a compact Kähler manifold with cardinality bigger than $1 - \varepsilon$ times the dimension of the space of global holomorphic sections to $A^k$.

1. Introduction

In [15], the authors construct what are now known as Ryll–Wojtaszczyk polynomials. These are the elements of a sequence $\{W_k\}_{k \geq 1}$ of homogeneous polynomials of degree $k \geq 1$ in $n$ complex variables such that they are of $L^2$-norm 1 on the unit sphere in $\mathbb{C}^n$ and uniformly bounded there. These polynomials have proved to be very useful to construct functions with precise growth restrictions and most notably they can be used to construct inner functions in the unit ball in several variables, see [1]. For a beautiful monograph about the construction of inner functions in several variables and related problems, we refer the reader to [14].

The existence of inner functions in the unit ball $\mathbb{B}_m$ of $\mathbb{C}^m$, for $m > 1$, was an open problem for many years. As inner functions are (up to multiplication by constants) those $f \in H^2(\mathbb{B}_m)$ such that $\|f\|_{\infty} = \|f\|_2$, it was natural to try to find first uniformly bounded sequences of polynomials. In the unit ball of $\mathbb{B}_2 \subset \mathbb{C}^2$, Bourgain, in [4], found a uniformly bounded orthonormal basis of $H^2(\mathbb{B}_2)$ by constructing a sequence of bounded orthonormal bases of the spaces of holomorphic homogeneous polynomials in $\mathbb{B}_2$. The same question in higher dimensions remains open. Specifically, it is not known if there exist uniformly bounded orthonormal bases for the spaces of homogeneous holomorphic polynomials in $\mathbb{B}_m$, for $m > 2$. (During the revision of this paper, Bourgain presented the construction of a uniformly bounded basis in the spaces of complex homogeneous polynomials on the unit ball of $\mathbb{C}^3$, see [5].) We observe that the existence of Ryll-Wojtaszczyk polynomials, that is, just one bounded polynomial for each degree, implies that $H^2(\mathbb{B}_m)$ do have a uniformly bounded orthonormal basis formed by polynomials for any $m > 2$, the idea of the construction is due to Olevskii [11, Chapter 4]. See also [14, Appendix I] where a better bound (independent of the dimension) for the elements of the basis is obtained by using powers of an inner function instead of Ryll-Wojtaszczyk polynomials.

The space of homogeneous holomorphic polynomials of degree $k$ in $\mathbb{C}^m$ can be identified with the space $H^0(\mathbb{C}P^{m-1}, A^k)$ of global holomorphic sections of the $k$-power of the hyperplane bundle $A \to \mathbb{C}P^{m-1}$ which is endowed with the Fubini–Study metric, so that the $L^2$ norm of the section is the same as the $H^2(\mathbb{B}_m)$ norm of the polynomial. Thus, it is possible to consider the same problem of existence of bounded orthonormal basis in a more general setting. In [16], Shiffman constructs a uniformly bounded orthonormal system of sections
of powers $A^k$ of a positive holomorphic line bundle over a compact Kähler manifold $M$. He proves that the number $n_k$ of sections in the orthonormal system is at least $\beta \dim H^0(M, A^k)$, where $0 < \beta < 1$ is a number that depends only on the dimension of $M$. These orthonormal sections are built in [16] by using linear combinations of reproducing kernels peaking at points situated in a lattice-like structure on the manifold. In the same paper, Shiffman raises the question whether using reproducing kernels peaking at Fekete points one may increase the size of the uniformly bounded orthonormal system of sections. We provide a positive answer to this question.

We proceed as follows: It is known that an arbitrarily small perturbation of an array of Fekete points gives an interpolating sequence, see [9, 13]. Then we use Jaffard’s theorem on ‘well localized’ matrices, together with the interpolation property, to deduce that the inverse of the Gramian matrix defined through the kernels defines a bounded operator in $\ell^\infty$. Finally, we construct the bounded orthonormal sections by following the same arguments as in [16].

One of our main ingredients is that, given $\varepsilon > 0$, it is possible to find interpolating sequences for $H^0(M, A^k)$ with cardinality $(1 - \varepsilon) \dim H^0(M, A^k)$. It is also known, see [9], that there is no (uniform) Riesz basis of reproducing kernels in the space of sections of $H^0(M, A^k)$. Thus this approach cannot provide uniformly bounded orthonormal basis of sections in $H^0(M, A^k)$ which would be the ultimate goal.

We will consider not only the complex manifolds setting (as in [16]) but we deal also with a real variant of the problem. In particular, we consider spaces generated by eigenfunctions for the Laplace–Beltrami operator on certain compact Riemannian manifolds. The main example is the sphere $S^m$ in $\mathbb{R}^{m+1}$ and the corresponding spaces of polynomials of degree at most $k$. Our aim is to construct many uniformly bounded orthonormal polynomials of degree at most $k$ in $m + 1$ variables restricted to a sphere in $\mathbb{R}^{m+1}$. We observe that there is no orthonormal basis of reproducing kernels for the space of polynomials of degree at most $k$, as this would be equivalent to the existence of tight spherical $2k$-design [2]. It is not known if there is a (uniform) Riesz basis of reproducing kernels [10]. In any case, as before, our approach cannot provide uniformly bounded orthonormal basis.

The proof in this real setting has one extra difficulty when compared to the positively curved holomorphic line bundle setting, because in the real setting the off-diagonal decay of the corresponding reproducing kernel is not fast enough to make the same argument work and some changes are needed. Thus we prefer to present the proof of the more delicate problem, that is, the Riemannian setting, and we will point out along the way which are the relevant changes to make in the complex setting.

2. Main results

Our result in the complex manifold setting reads as follows.

**THEOREM 2.1.** Let $A \to M$ be a Hermitian holomorphic line bundle over a compact Kähler manifold $M$ with positive curvature. Then for any $\varepsilon > 0$, there is a constant $C_\varepsilon$ such that for any $k \in \mathbb{Z}^+$, we can find orthonormal holomorphic sections:

$$s_1^k, \ldots, s_{n_k}^k \in H^0(M, A^k), \quad n_k \geq (1 - \varepsilon) \dim H^0(M, A^k),$$

such that $\|s_j^k\|_\infty \leq C_\varepsilon$ for $1 \leq j \leq n_k$ and for all $k \in \mathbb{Z}^+$.

For $M = \mathbb{CP}^{m-1}$ and $A$, the hyperplane section bundle $\mathcal{O}(1)$ endowed with the Fubini–Study metric, one can identify $H^0(\mathbb{CP}^{m-1}, A^k)$ with the space $H_k(\mathbb{B}_m)$ of homogeneous holomorphic polynomials of degree $k$ on $\mathbb{C}^m$. Then the theorem above gives us the following result.
COROLLARY 2.2. For all $m, k \geq 1$ and any $\varepsilon > 0$, there is a constant $C_\varepsilon$ and a system of orthonormal homogeneous holomorphic polynomials

$$p_1^k, \ldots, p_{n_k}^k \in H_k(\mathbb{B}_m), \quad n_k \geq (1 - \varepsilon) \dim H_k(\mathbb{B}_m),$$

such that $\|p_j^k\|_{L^\infty(S^{2m-1})} \leq C_\varepsilon$ for $1 \leq j \leq n_k$.

Let $(M, g)$ be a compact Riemannian manifold of dimension $m \geq 2$. Let $dV$ be the volume element. The (discrete) spectrum of the Laplace–Beltrami operator is a sequence of eigenvalues

$$0 = \lambda_0 < \lambda_1^2 \leq \lambda_2^2 \leq \ldots \rightarrow \infty,$$

and we consider the corresponding orthonormal basis of eigenfunctions $\phi_i$ (so we have $\Delta \phi_i = -\lambda_i^2 \phi_i$). Consider the following subspaces of $L^2(M)$:

$$E_L = \text{span}_{\lambda_i \leq L} \{\phi_i\}.$$

We denote $\dim E_L = k_L$. By Weyl’s law $k_L \sim L^m$.

DEFINITION 2.3. We say that a compact Riemannian manifold is admissible if it satisfies the following product property: there exists a constant $C > 0$ such that for all $0 < \varepsilon < 1$ and $L \geq 1$:

$$E_L \cdot E_{\varepsilon L} \subset E_{L(1+C\varepsilon)}.$$

In [12], this notion was introduced to study Fekete points in compact Riemannian manifolds. There it was proved that the sphere and the projective spaces over the fields $\mathbb{R}$, $\mathbb{C}$ and $\mathbb{H}$ are admissible manifolds. Moreover, the product of two admissible manifolds is admissible.

The reproducing kernels of $E_L$ are given by

$$B_L(z, w) = \sum_{i=1}^{k_L} \phi_i(z)\overline{\phi_i(w)}.$$

These are functions defined by the properties that, for any $w \in M$, we have that $B_L(\cdot, w) \in E_L$ and $\langle \phi, B_L(\cdot, w) \rangle = \langle \phi, w \rangle$, when $\phi \in E_L$. It is known that $\|B_L(\cdot, w)\|_{L^2(M)}^2 = B_L(w, w) \sim L^m$ and also $k_L \sim L^m$, see [7]. We denote by $b_L(z, w) = B_L(z, w)/\|B_L(\cdot, w)\|_{L^2(M)}$ the normalized reproducing kernels.

The main example is the sphere $M = S^m$, where the eigenfunctions $\phi_i$ are spherical harmonics and the spaces $E_L$ are the restriction to the sphere of spaces of polynomials in $\mathbb{R}^{m+1}$. In particular, the restriction to $S^m$ of polynomials of degree at most $L$ corresponds to $E_{L(L+m-1)}$.

Our result is the following theorem.

THEOREM 2.4. Let $M$ be an admissible manifold. Given $\varepsilon > 0$, there exists $C_\varepsilon > 1$ such that for each $L \in \mathbb{Z}^+$ there is a set $\{s_{1L}, \ldots, s_{n_LL}\}$ of orthonormal functions in $E_L$ with $n_L \geq (1 - \varepsilon) \dim E_L$ such that $\|s_{1L}\|_{L^\infty(M)} \leq C_\varepsilon$, for $1 \leq j \leq n_L$.

As we mentioned before, we use Fekete arrays in the construction of the orthonormal functions.

DEFINITION 2.5. Let $\{\psi_1, \ldots, \psi_{k_L}\}$ be any basis in $E_L$. A set of points $x_1^*, \ldots, x_{k_L}^* \in M$ such that

$$|\det(\psi_1(x_i^*))|_{i,j} = \max_{x_1, \ldots, x_{k_L} \in M} |\det(\psi_1(x_j))|_{i,j}$$

is a Fekete set of points of degree $L$ for $M$.  

BOUNDED ORTHONORMAL POLYNOMIALS 885
Fekete points are well-suited points for interpolation formulas and numerical integration. One reason is that the corresponding Lagrange polynomials are bounded by 1. We use the interpolating properties of these Fekete points. In the following lines, we provide the definition of interpolating arrays and some related concepts. For any degree \( L \), we take \( m_L \) points in \( M \)

\[
Z(L) = \{ z_{L,j} \in M : 1 \leq j \leq m_L \}, \quad L \geq 0,
\]

and assume that \( m_L \to \infty \) as \( L \to \infty \). This yields a triangular array of points \( Z = \{ Z(L) \}_{L \geq 0} \) in \( M \).

**Definition 2.6.** Let \( Z = \{ Z(L) \}_{L \geq 0} \) be a triangular array with \( m_L \leq k_L \) for all \( L \). We say that \( Z \) is interpolating for the spaces \( E_L \), if for all arrays \( \{ c_{L,j} \}_{L \geq 0, 1 \leq j \leq m_L} \) of values such that

\[
\sup_{L \geq 0} \frac{1}{k_L} \sum_{j=1}^{m_L} |c_{L,j}|^2 < \infty,
\]

there exists a sequence of functions \( Q_L \in E_L \) uniformly bounded in \( L^2(M) \) such that \( Q_L(z_{L,j}) = c_{L,j} \), for \( 1 \leq j \leq m_L \), and for all \( L \).

An equivalent definition is the following. The array \( Z \) is interpolating if and only if the normalized reproducing kernel of \( E_L \) at the points \( Z(L) \) form a Riesz sequence, that is,

\[
C^{-1} \sum_{j=1}^{m_L} |a_{L,j}|^2 \leq \int_M \left| \sum_{j=1}^{m_L} a_{L,j} b_L(z, z_{L,j}) \right|^2 dV(z) \leq C \sum_{j=1}^{m_L} |a_{L,j}|^2,
\]

for any \( \{ a_{L,j} \}_{L,j} \) with \( C > 0 \) independent of \( L \). This explains the factor \( 1/k_L \) in Definition 2.6; it corresponds to the normalization \( B_L(z_{L,j}, z_{L,j}) \sim k_L \sim L^m \).

It is well known also that the interpolating property is equivalent to saying that the Gramian matrices

\[
G_L = G = ( (b_L(\cdot, z_{L,i}), b_L(\cdot, z_{L,j}))_{i,j} = (L^{-m/2} b_L(z_{L,i}, z_{L,j}))_{i,j}
\]

define uniformly bounded operators in \( L^2 \) which are uniformly bounded below, where uniformly means with respect to \( L \), see [6, p. 66].

A nice property of interpolating sequences is that they are uniformly separated. We denote by \( d(u, v) \) the geodesic distance between \( u, v \in M \).

**Definition 2.7.** An array \( Z = \{ Z(L) \}_{L \geq 0} \) is uniformly separated if there is a positive number \( \varepsilon > 0 \) such that

\[
d(z_{L,j}, z_{L,k}) \geq \frac{\varepsilon}{L+1} \quad \text{if} \quad j \neq k,
\]

for all \( L \geq 0 \).

The right-hand side inequality in (2.2) holds if and only if \( Z \) is uniformly separated, see [10, 13]. The next result provides us with Riesz sequences of reproducing kernels with cardinality almost optimal. See [9] for the definition of separation in the complex setting, and [9, 13] for a proof of the following result in the two different settings we are considering.

**Theorem 2.8.** Let \( M \) be an admissible manifold. Given \( L \geq 0 \), let \( Z(L) \) be a set of Fekete points of degree \( L \) for \( M \). Then, for any \( \varepsilon > 0 \), the array \( \{ Z(L^-) \}_{L \geq 0} \) is interpolating for the spaces \( E_L \), where \( L^- = (1-\varepsilon)L \).
Remark 2.9. This is the only point in the real setting that one uses the hypothesis that $M$ is admissible. In [13], the admissibility is needed to establish the connection between Fekete points and interpolating arrays. The equivalent version of Theorem 2.8 that we need is the following: if $Z(L)$ a set of Fekete points of degree $L$ for $M$, then $Z(L)$ is interpolating for the spaces $E^{L^I}_+$ where $L^I_+ = (1 + \varepsilon)L$.

The theorem above shows that the normalized reproducing kernels $\{b_L(\cdot, z)\}_{z \in Z(L)}$ form a Riesz sequence. In the compact complex manifolds setting, one can use directly these kernels to continue with the construction of sections satisfying the conclusions of Theorem 2.1. This is because the Bergman kernel $B_k$ of the $k$th power of a positively curved holomorphic line bundle over a compact complex manifold of dimension $m$ has very fast off-diagonal decay, see [3]:

$$|B_k(z, w)| \lesssim k^m e^{c \sqrt{d} d(z, w)}.$$

Unfortunately, when working with Riemannian manifolds the off-diagonal decay of the reproducing kernels is not fast enough. So we are going to introduce better kernels.

Definition 2.10. Given $0 < \varepsilon \leq 1$, let $\beta_\varepsilon : [0, +\infty) \to [0, 1]$ be a nonincreasing $C^\infty$ function such that $\beta_\varepsilon(x) = 1$ for $x \in [0, 1 - \varepsilon]$ and $\beta_\varepsilon(x) = 0$ if $x > 1$. We consider the following Bochner-Riesz type kernels

$$B^*_L(z, w) = \sum_{k=1}^{k_L} \beta_\varepsilon \left( \frac{\lambda_k}{L} \right) \phi_k(z) \overline{\phi_k(w)}.$$

In the limiting case, when $\varepsilon = 0$, we recover the reproducing kernel for $E_L$. Observe that one obtains easily, from the corresponding result for the reproducing kernel, that $\|B^*_L(\cdot, w)\|_2 \sim L^m$ for any $w \in M$. The main advantage of these modified kernels is that they have better pointwise estimates than the reproducing kernels. The following was proved in [17]:

$$|B^*_L(z, w)| \lesssim C_{\varepsilon, N} \frac{L^m}{(1 + L d(z, w))^N}, \quad z, w \in M,$$

where one can take any $N > m$ (changing the constant). The bound for the reproducing kernel is the same than (2.3) with $N = 1$. As before, we denote by lower-case $b^*_L(z, w)$ the normalized kernel.

Our next result shows that one may replace the reproducing kernels by the Bochner-Riesz type and still get a Riesz sequence.

Lemma 2.11. Given $\varepsilon > 0$, there exists a set of $n_{L, \varepsilon}$ points $\{z_j\}_{j=1, \ldots, n_{L, \varepsilon}}$ with $n_{L, \varepsilon} \geq (1 - \varepsilon) \dim E_L$ such that the normalized Bochner-Riesz type kernels $\{b^*_L(\cdot, z_j)\}_{j=1, \ldots, n_{L, \varepsilon}}$ form a Riesz sequence with uniform bounds, that is,

$$C^{-1} \sum_{j=1}^{n_{L, \varepsilon}} |a_j|^2 \leq \int_M \left| \sum_{j=1}^{n_{L, \varepsilon}} a_j b^*_L(z, z_j) \right|^2 dV(z) \leq C \sum_{j=1}^{n_{L, \varepsilon}} |a_j|^2,$$

for any $\{a_j\}_j$ with $C > 0$ independent of $L$.

Proof. We choose the points $z_j$ for $j = 1, \ldots, k(1 - 2\varepsilon)L$ to be a Fekete array in $E_{(1 - 2\varepsilon)L}$. It is clear that by an application of Theorem 2.8 (see Remark 2.9) they are an interpolating array for $E_{(1 - \varepsilon)L}$. We denote $n_{L, \varepsilon} = k(1 - 2\varepsilon)L$. 

The right-hand side inequality in (2.4) follows essentially from the uniform separation of the sequence. Indeed, let

$$S_{L,\varepsilon}(a) = \sum_{j=1}^{n_{L,\varepsilon}} a_j b_L^j(z, z_j).$$

By duality and $\|B_L^j(\cdot, w)\|_2^2 \sim L^m$:

$$\|S_{L,\varepsilon}(a)\|_2 = \sup_{\|P\|_2=1} |\langle P, S_{L,\varepsilon}(a) \rangle| \sim \frac{1}{L^{m/2}} \sup_{\|P\|_2=1} \left| \sum_{j=1}^{n_{L,\varepsilon}} a_j \int_M B_L^j(z_j, w) P(w) \, dV(w) \right|. $$

The set $\{z_j\}_{j=1,...,n_{L,\varepsilon}}$ is uniformly separated and Plancherel–Polya inequality says that

$$\frac{1}{k_L} \sum_{j=1}^{n_{L,\varepsilon}} |\phi(z_j)|^2 \lesssim \|\phi\|_2^2,$$

for all $\phi \in E_L$, see [12, Theorem 4.6]. Therefore,

$$\frac{1}{k_L} \sum_{j=1}^{n_{L,\varepsilon}} \left| \int_M B_L^j(z_j, w) P(w) \, dV(w) \right|^2 \lesssim \left\| \int_M B_L^j(\cdot, w) P(w) \, dV(w) \right\|_2^2 \lesssim \|P\|_2^2.$$

By Cauchy–Schwarz, we get the desired inequality.

For the left-hand side in (2.4), let $P_{(1-\varepsilon)L}$ be the orthogonal projection from $L^2(S^d)$ onto $E_{(1-\varepsilon)L}$. Then as $P_{(1-\varepsilon)L}(B_L^j(\cdot, w)) (z)$ is the reproducing kernel in $E_{(1-\varepsilon)L}$, and $z_j$ for $j = 1, \ldots, n_{L,\varepsilon}$ is interpolating for $E_{(1-\varepsilon)L}$

$$\sum_{j=1}^{n_{L,\varepsilon}} |a_j|^2 \lesssim \|P_{(1-\varepsilon)L}|S_{L,\varepsilon}(a)\|_2^2 \lesssim \|S_{L,\varepsilon}(a)\|_2^2. \quad \square$$

Given $\varepsilon > 0$, let $z_j$ for $j = 1, \ldots, n_{L,\varepsilon}$ be the points given by Lemma 2.11 and let

$$\Delta = (\Delta_{ij})_{i,j=1,...,n_{L,\varepsilon}} = \begin{pmatrix} (b_L^1(\cdot, z_1), b_L^1(\cdot, z_1)) & \cdots & (b_L^1(\cdot, z_{n_{L,\varepsilon}}), b_L^1(\cdot, z_{n_{L,\varepsilon}})) \\ \vdots & \ddots & \vdots \\ (b_L^{n_{L,\varepsilon}}(\cdot, z_{n_{L,\varepsilon}}), b_L^{n_{L,\varepsilon}}(\cdot, z_{n_{L,\varepsilon}})) & \cdots & (b_L^{n_{L,\varepsilon}}(\cdot, z_{n_{L,\varepsilon}}), b_L^{n_{L,\varepsilon}}(\cdot, z_{n_{L,\varepsilon}})) \end{pmatrix}$$

be the $n_{L,\varepsilon} \times n_{L,\varepsilon}$ corresponding Gramian matrix. This matrix defines a uniformly bounded operator in $L^2$ which is also bounded below uniformly.

It is clear that one can apply the estimate (2.3) to the Bochner-Riesz type kernel with coefficients given by the function $\beta^2(x)$ getting

$$|\Delta_{ij}| \sim \frac{1}{L^m} \left| \int_M B_L^j(z, z_i) B_L^i(z, z_j) \, dV(z) \right| \lesssim \int_M \frac{L^m \, dV(z)}{(1 + Ld(z, z_i))^{N}(1 + Ld(z, z_j))^{N}}.$$

We are going to estimate the last integral. Define the sets $A = \{z \in M : 2d(z, z_i) \geq d(z_i, z_j)\}$ and $B = \{z \in M : 2d(z, z_j) \geq d(z_i, z_j)\}$. Clearly, $A = M \cup B$, and

$$\int_A \frac{L^m \, dV(z)}{(1 + Ld(z, z_i))^{N}(1 + Ld(z, z_j))^{N}} \lesssim \frac{1}{(1 + Ld(z_i, z_j))^{N}} \int_M \frac{L^m \, dV(z)}{(1 + Ld(z, z_j))^{N}}.$$

Now

$$\int_M \frac{L^m}{(1 + Ld(z, z_j))^{N}} \, dV(z) = L^m \int_0^1 V\left(\{w \in M : (1 + Ld(z_j, w))^{-N} > t\}\right) \, dt,$$

and using that for geodesic balls $V(B(z, r)) \sim r^m$ one can bound the integral above by a constant times $L^{-m} \int_0^1 t^{-m/N} \, dt$. (2.5)
The same estimate holds for the integral over $B$, therefore we have proved that
\[ |\Delta_{ij}| \lesssim \frac{1}{(1 + Ld(z_i, z_j))^N}. \tag{2.6} \]

To define our uniformly bounded functions, we will use the entries of matrix $\Delta^{-1/2}$. The following localization result by Jaffard [8, Proposition 3] says basically that if we have an invertible matrix in $\ell^2$ which is well localized on the diagonal, its inverse matrix is also localized along the diagonal and thus bounded in $\ell^p$.

**Theorem 2.12 (Jaffard).** Let $(X, d)$ be a metric space such that for all $\varepsilon > 0$ there exists $C_\varepsilon$ with
\[ \sup_{s \in X} \sum_{t \in X} \exp(-\varepsilon d(s, t)) \leq C_\varepsilon \]
and that for a given $N > 0$
\[ \sup_{s \in X} \sum_{t \in X} \frac{1}{(1 + d(s, t))^N} = B < \infty. \]
Let $A = (A(s, t))_{s, t \in X}$ be a matrix with entries indexed by $X$ and such that for $\alpha > N$
\[ |A(s, t)| \leq \frac{C}{(1 + d(s, t))^{\alpha}}. \tag{2.7} \]
Then, if $A$ is invertible as an operator in $\ell^2$, then the entries of the matrix $A^{-1}$ (and also $A^{-1/2}$ when $A$ is positive definite) satisfy the same kind of bound (2.7), and therefore the operators defined by these matrices are bounded in $\ell^p$ for $1 \leq p \leq \infty$, with bounds depending only on the constants $C_\varepsilon, B$ and $C$.

The following proposition allows us to apply Jaffard’s result to the matrix $\Delta$ and it will be used also to bound our orthonormal functions. We observe that it is precisely in this point where we need estimate (2.3). As we mentioned before, the reproducing kernel can be bounded with the same bound as in (2.3) but just with $N = 1$.

**Proposition 2.13.** Let $\{z_j\} \subset M$ be uniformly separated and let $N > m$. Then
\[ \sup_{z \in M} \sum_j \frac{1}{(1 + Ld(z, z_j))^N} \lesssim 1. \]

**Proof.** Let $\delta > 0$ be the separation. Assume that $d(z, z_j) \geq \delta/(L + 1)$ for all $j$. Then $d(z, w) \leq \frac{3}{2} d(z, z_j)$ for $w \in B_j = \{ w \in M : d(z, w) < \delta/2(L + 1) \}$. Therefore, arguing as in (2.5) we get
\[ \sum_j \frac{1}{(1 + Ld(z, z_j))^N} \lesssim L^m \sum_j \int_{B_j} \frac{1}{(1 + Ld(z, w))^N} dV(w) \]
\[ \leq L^m \int_M \frac{1}{(1 + Ld(z, w))^N} dV(w) \leq C. \]
The case when $d(z, z_j) < \delta/(L + 1)$ for some $j$ follows easily. \qed

We apply Jaffard’s result to the matrix $\Delta$ considering the distance $d(i, j) = Ld(z_i, z_j)$ in $X = \{1, \ldots, n_{L, \varepsilon}\}$ and the estimate (2.6). The two required properties in Theorem 2.12 can be easily deduced as in Proposition 2.13 so we get
\[ |\Delta_{ij}^{-1/2}| \lesssim \frac{1}{(1 + Ld(z_i, z_j))^N} \]
and
\[ \|\Delta^{-1/2}\|_{\ell^\infty \to \ell^\infty} = \max_i \sum_j |\Delta^{-1/2}_{ij}| \lesssim 1. \]

To define the orthonormal functions, we follow [16]. Denote \( \Delta^{-1/2}_{ij} = B_{ij} \) and define the orthonormal set of functions from \( E_L \)
\[ \Psi^L_i = \sum_j B_{ij} b^L_\varepsilon (\cdot, z_j). \]
And then the functions from \( E_L \)
\[ s^L_i = \frac{1}{\sqrt{n_{L,\varepsilon}}} \sum_j \zeta_{ji} \Psi^L_j, \]
where \( \zeta = e^{2\pi i / n_{L,\varepsilon}} \). They are orthonormal because
\[ \langle s^L_i, s^L_k \rangle = \frac{1}{n_{L,\varepsilon}} \sum_{j=1}^{n_{L,\varepsilon}} \zeta_{ji} = \delta_{ik}, \quad 1 \leq i, k \leq n_{L,\varepsilon}. \]

To verify that the \( s^L_i \) are indeed uniformly bounded we define the linear maps
\[ F_L : \mathbb{C}^{n_{L,\varepsilon}} \to E_L, \quad v = (v_i) \mapsto \sum_j v_j b^L_\varepsilon (\cdot, z_j). \]
Again, by Proposition 2.13, these maps have \( \ell^\infty \) to \( L^\infty (M) \) norm bounded by
\[ \sup_{z \in M} \sum_j |b^L_\varepsilon (z, z_j)| \lesssim L^{m/2} \sup_{z \in M} \sum_j \frac{1}{(1 + Ld(z, z_j))^N} \lesssim L^{m/2}. \]
So, finally we get
\[ \|s^L_i\|_{L^\infty (M)} \leq \frac{1}{\sqrt{n_{L,\varepsilon}}} \|F_L\|_{\ell^\infty \to L^\infty (M)} \|\Delta^{-1/2}\|_{\ell^\infty \to \ell^\infty} \lesssim 1, \]
for all \( L \in \mathbb{Z}^+ \) and \( 1 \leq i \leq n_{L,\varepsilon} \).

Acknowledgements. We would like to thank the referee for a careful review of the paper.
